AN INTRODUCTION TO GYNECOLOGY. By C. JEFF MILLER, M.D. Quarto of 327 pages, illustrated. St. Louis, The C. V. Mosby Company, 1931. Cloth, $5.00.

BOOK REVIEWS

THE MORBID PERSONALITY Psycho Analytical Studies in the Structure of Character and Personality By SANDOR LORAND, M D Octavo of 181 pages New York, Alfred A Knopf, 1931 Cloth $3 00

Following the basic work of Freud and his followers, Doctor Lorand demonstrates that the primitive sexual instincts play so clamorous a role in the evolution of personality that they cannot be ignored

As Doctor Brill suggests in his foreword, psychiatry *has never learned anything from the adjusted, normal person* Doctor Lorand has chosen to present his subject by the study of the character development in ten typical patients whose personalities have deviated from the normal to an extent that they sought the assistance of the psycho-analyst *Analysis in each case demonstrated* early arrest and fixation of natural sexual development

Doctor Lorand approaches his subject with profound sympathy for the individual entangled in the bonds of sex *We are accustomed as medical men,"* he writes to believe any complaints of somatic or physical nature which the patients bring to us Why not show more tolerance towards granting the possibility of mental torture? There is much truth in the complaint of the neurotic *that no one understands him, that everyone is* against him, and that he is accused of imagining things because he has no physical signs of illness"

Written primarily for the physician and the psychiatrist, Doctor Lorand's text will be of service, also to *educators* and social workers in helping them more sympathetically to understand the sex perversions and anti social demonstrations which come within their ken It presupposes a knowledge of scientific terminology and deals at length with eroticism

The book has sixty two bibliographical references both from the foreign and English psychiatry texts

FREDERIC DAMRAU

BIO-ASSAYS A HANDBOOK OF QUANTITATIVE PHARMACOLOGY By JAMES C MUNCH Octavo of 958 pages illustrated Baltimore The Williams & Wilkins Company, 1931 Cloth, $10 00

The author has succeeded admirably in presenting in logical fashion the important factors, technique and method of quantitative pharmacology More than five thousand references are divided into groups according to subject matter and placed at the end of the chapter on which they have bearing The mere fact that it was necessary to tabulate *so many articles indicates* the chaotic state of this subject and the unnecessary duplication of work by various investigators

The second and third chapters deal with experimental technique, supplemented by ink sketches of the sites of *of results The drugs with* ty of each are listed rather predominant action as those affecting the nervous system circulation respiration and the muscles, with one chapter each on glandular products and special types of drugs The chapter on the circulation is quite voluminous and complete, the part allotted to the chemical and physiological assay of heart stimulants, such as digitalis strophanthus, squill, etc is especially detailed The other drugs are dealt with in a similar manner, the author having compiled a mass of data and presented it in a form that is readily utilizable.

METHODS AND PROBLEMS OF MEDICAL EDUCATION (Fifteenth Series) Quarto of 76 pages, illustrated New York, The Rockefeller Foundation, 1929

The fifteenth series of these Rockefeller brochures is devoted entirely to Albany Medical College The teaching methods of the various departments are described and floor plans including the Albany Hospital are included The photographs are excellent C A G

THE PRACTICAL MEDICINE SERIES Comprising Eight Volumes on the Year's Progress in Medicine and Surgery Series 1930 Chicago, The Year Book Publishers, 1930 General Medicine Edited by GEORGE H WEAVER, M D, and others 12mo of 848 pages illustrated Cloth, $3 00

This volume on 'General Medicine, Series 1930,' presents in the usual thorough and comprehensive manner, the advancement made upon the subject of general medicine *The departments of the volume* are separated into the infectious diseases, diseases of the chest, excepting the heart, diseases of the blood and blood making organs, diseases of the kidney, diseases of heart and blood vessels and diseases of the digestive system and metabolism *It is impossible to give in detail* the newer aspects of the diseases reviewed in this year book The editor of each department has thoughtfully presented the advances A study of this volume will well repay the time taken to keep abreast of the times It is indeed, surprising to learn how *much can be presented in so* small a space with the typographical work so agreeably done.

HENRY MONROE MOSES

THE THEORY OF OBSTETRICS A functional study of child bearing based on a new definition of normal labor and on a new theory of uterine inertia By M C DE GARIS M D Octavo of 272 pages New York, William Wood and Company, 1931 Cloth $5 00

The author gives us a functional study of child bearing, based on a new definition of normal labor, and on a new theory of uterine inertia The book is illustrated by a detailed statistical analysis of one hundred consecutive labors, and *some records of cases of painless* labor

The writer argues for a new standard for normal labor—one in which the mother will in a short time deliver herself spontaneously of a healthy baby with but little *pain or distress*

He contends that if all other types of labor are considered abnormal, more attention would be focused on some of the unsolved problems of childbirth Why do most labors cause pain? What causes uterine inertia? He makes a *plea for more studies* in regard to physiology of pregnancy and labor, and he is of the opinion that long and painful labors are more often due to abnormal maternal physiology than to faulty mechanism The high mortality and morbidity rate in obstetric patients is viewed with grave *concern* and the writer seeks to find a part of the cause in poor general health of the patient foci of infection faulty diet etc. Whether or not the reader agrees with the author, it must be admitted that he views pregnancy and labor from a new and unusual angle The book is *most interesting,* and is worth reading by teachers as well as by clinicians

SPECIALISTS' CERTIFICATION IN NEW JERSEY

The June issue of the Journal of the Medical Society of New Jersey contains a plan for certifying specialists presented to the meeting of the Second District Branch of New Jersey. The report is as follows:

"(I) Formation of a State Society Committee on Credentials for accrediting members for special practice, with subsidiary county committees to refer approved applicants to the state committee for action. These committees might be formed as follows: State—President, ex-officio, the Chairman of the Welfare Committee, Chairman of Publicity Committee, Chairman of Board of Trustees, and member of the State Examining Board.

"County—12 members, with the president ex-officio; the members to be chiefs of departments or ranking attendings in their respective hospitals, and members of the colleges or groups now nationally accrediting physicians for special practice, apportioned as follows: Surgery 2, Medicine 2, Obstetrics 1, Eye and Ear 1, Nose and Throat 1, Roentgenology 1, Genito-Urinary 1, General Practice 1, Gynecology 1, Pediatrics 1.

"(II) Requirements for Acceptance as Specialists:

"(1) Those accepted by the respective groups of specialists gathered under the following Societies and Colleges:

"(a) American College of Surgeons.

"(b) American College of Physicians.

"(c) American Society of Obstetricians and Gynecologists.

"(d) American Boards of Otolaryngology and Ophthalmology.

"(e) American College of Radiology and the Radiologic Society of North America.

"(f) American Society of Psychiatrists.

"(2) Accrediting by recognition of experience:

"(a) Men in practice longer than 10 years who have been notably identified with certain branches of medicine and surgery and who are accepted in their communities by their fellow practitioners as competent in the field to which they are giving special attention.

"(b) Men in general practice, holding a hospital service in a special branch of medicine, which service is sufficiently active to allow of attainment of a high degree of proficiency in that branch of medicine. The duration of appointment must be not less than five years.

"(c) Properly qualified and trained men, not classified in (a) and (b). Those of ample hospital and post-graduate training in practice five years or more, who furnish proof of qualifications which are acceptable to the State Committee on Credentials.

"(III) Distribution of Information Regarding Accrediting of Members for Special Practice and Those So Accredited:

"(1) Newspaper notices, prepared by County Committee on Credentials and certified by the State Committee on Credentials.

"(2) Radio talks; best through the State Committee.

"(3) Through agency of the medical profession; office placards and pamphlets on the subject of 'Choosing a Specialist.'

"(4) Display of Certificate issued by the State Society through the State Committee on Credentials for Special Practice.

"(5) Distribution of information through a Central information Office in each county medical district; (a) Physicians' and Surgeons' Telephone Exchange; (b) Secretary's Office of the County Society."

CHILD HEALTH CONFERENCE IN NEW JERSEY

The June number of the Journal of the Medical Society of New Jersey contains a description of a State conference on Child Health and Protection, held on April 17 and 18, in the New Jersey College for Women in New Brunswick. It had been called by Governor M. F. Larson in order to "Measure the State's facilities and program with the standards set by the White House Conference; and to make recommendations for State action."

"The conference was conducted by the New Jersey Conference of Social Work, of which William J. Ellis is President, in cooperation with the four major state departments that deal with the child; the Department of Education,

OVER THREE GENERATIONS

the standard barley flour for infant and invalid feeding

(1) In the feeding of infants as a modifier of cow's milk and source of carbohydrate—

(2) In the treatment of infant diarrhea or other digestive disturbances—

(3) In the treatment of intestinal and kidney disorders—

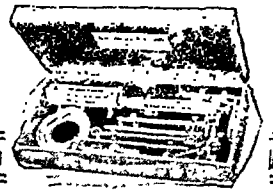
(4) As an adjunct to diet after surgical operations—

MANY specialists today are specifying *Robinson's "Patent" Barley* because it is a finely milled barley flour, and they are sure of a product prepared in a strictly hygienic factory from the finest barley. It is subjected to routine biochemical and bacteriological tests in order to control its quality.

The result is that a physician can prescribe *Robinson's "Patent" Barley* in the knowledge that it is a uniform and clean product, free from irritating husks and from bleaching agents. It is readily available in drug stores throughout the country.

ROBINSON'S *"PATENT"* BARLEY

ELECTRICALLY LIGHTED SURGICAL INSTRUMENTS



OUTSTANDING PERFECTION IN QUALITY AND DESIGN

. . . of "E. S. I. Co." electrically-lighted diagnostic and surgical instruments accounts for the confidence physicians and surgeons place in our complete line for specialists in practically every field.

The imprint "E. S. I. Co." is your guarantee of quality and service. Behind it are thirty years of experience which, coupled with the experience and direction of eminent physicians and surgeons, assures you of dependable, accurate electrically-lighted instruments.

without a dissenting voice, as follows: Resolved that the Welfare Committee of the State Society be urged to secure, if possible, at the coming session of the legislature an amendment of the hospital lien law to include doctors and nurses.

"Dr. Waters, of Hudson, presented a careful résumé of the attitude of other states, Canada, and Europe, on the 'Problem of Licensing Specialists.' He then submitted a carefully thought out plan for proper accrediting and control of specialists and specialism by the State Medical Society. (Page 928.)

"Dr. Joseph R. Morrow, of Bergen, opened a discussion on the 'Supervision of Public Health Nursing,' and was followed by Drs. Knox, Marris and others.

"'The Need for Better Public Relations Through County Medical Society Publicity' was spoken of by Dr. Spencer T. Snedecor, of Bergen. This was discussed and the following motion passed: Resolved that the State Medical Society be asked to appoint a special committee for the promotion and supervision of county society publicity.

"Dr. Harry Perlberg, of Hudson, spoke on the problem of 'Medical Charity.'

"Dr. Wilbur, of Sussex, presented for consideration a 'Plan for Continuing Immunization Against Diphtheria.'

"Dr. Wayne Hall, of Passaic, discussed the subject of 'Pre-school Examinations,' and urged the need for a campaign to encourage this work.

"When the meeting adjourned it was felt that a great deal of fruitful discussion had been held on topics which are of vital interest to the general profession."

ANNUAL MEETING IN IOWA

The following editorial in the June issue of the Journal of the Iowa State Medical Society summarizes the editor's impressions of the eightieth annual meeting held on March 13-15, 1931, in Des Moines:

"The eightieth annual session of the Iowa State Medical Society, which recently convened in a three-day meeting in Des Moines, was generally conceded to have been the most outstanding in the history of the society." . . . "This year a new high mark in interest was demonstrated by a registration of 790. This fact alone demonstrates a healthy spirit of unity which has been developed during the past few years and could not prevail if dissensions existed without our membership.

(*Continued on page 933—adv. xv*)

(*Continued from page 932—adv. xiv*)

"Interest in the annual session of the Society was also strikingly demonstrated in the uniformly good attendance at every scientific session. In the past it has frequently been observed that following each presentation there was much restlessness and shifting of the audience. Members would take occasion to enjoy a friendly chat in the corridors while papers of lesser appeal were presented. This year the corridors were noticeably deserted during the time of the scientific programs and frequently between addresses the audience would not vary a score. Back of such interest was manifestly the exceptionally high type program which had been so thoughtfully prepared by the section chairmen. Every section of the state was duly represented and every phase of practice touched upon. By the aid of well placed and skillfully controlled loud speakers, the audience was uniformly enabled to hear and enjoy every presentation.

"The banquet and smoker bore testimony of the feeling of fraternity which permeated the entire group. Great credit was due the local arrangements committee for the splendid entertainment prepared for both the members and the visiting ladies. At all functions there was record attendance and accommodations were taxed to the limit.

"Most far-reaching perhaps in accomplishments was the resolution enabling the redistricting of the state for more uniform representation and in effecting an increase in dues sadly needed to carry on the enlarged activities of the organization. The program for redistricting the state as approved was chosen from a number suggested as being most equitable in representation and most workable from the standpoint of unity. It provides for eleven councilor districts formed as nearly as possible in rectangles in order to facilitate councilor activities. The dues for the ensuing year were advanced from $7.50 to $12.00."

PRESIDENT'S ADDRESS IN IOWA

The first article in the June issue of the Journal of the Iowa State Medical Society is the Presidential address given on May 13, by Dr. W. A. Rohlf, before the Eightieth Annual Meeting of the Iowa State Medical Society. Doctor Rohlf said in part:

"During the year I traveled 13,846 miles in the interest of the Iowa State Medical Society (and I hope it was for the best interest.) I addressed thirty county and other medical societies during this period. I made fifteen trips to Des Moines for meetings of various com-

To improve lactation

—when nursing infants do not thrive

ACTUAL RESULTS conclusively prove that Cocomalt is an important factor in stimulating lactation. It increases the flow and improves the quality of milk. *Because of its high caloric value* Cocomalt amply meets the demands made upon the nursing mother's strength and energy by the drain of lactation. Cocomalt is of assistance not only when lactation is inadequate—but for growing children, convalescents, nervous, run-down men and women.

A perfect galactagogue—quickly assimilated

Cocomalt provides all the necessary food elements for the production of milk. It contains Vitamins A, B Complex and D.

Mixed with milk, hot or cold, Cocomalt increases the caloric value of each glass 70%—adding 45% more protein, 48% more mineral salts, 184% more carbohydrates. It is easily digested, imposes no strain upon the digestion.

Available in 5 lb. cans for hospital use. Or at grocers and leading drug stores, in ½ lb. and 1 lb. sizes. Mail coupon for *free* trial can.

Cocomalt

DELICIOUS HOT OR COLD

ADDS 70% MORE NOURISHMENT TO MILK

mittees and other groups. This entailed fifty-five days of time. I am hoping that perhaps this effort on my part may have contributed in a small way to the accomplishments of the Iowa State Medical Society and allied medical and health agencies.

"The society can take just pride in the accomplishments of the Speakers Bureau; a detailed report will be available for your perusal. I predict that continued effort by this very efficient committee will bring results beyond the most sanguine hopes of those who originated its work in Iowa.

"It is gratifying to note that there is progress being made in the coordination of various organizations, lay and professional, in public health and hygiene. That the State Society is more active in this field than ever before is one of the results of the educational program of our Speakers Bureau. Closer relationship, better understanding, and greater efficiency for both the profession and the medical department of our State University is being brought about by the University Extension courses and by the work of the Medical Education and Hospitals Committee.

"I cannot refrain from expressing my appreciation of the splendid efforts put forth by the members of our legislative committee who were on the job all the time, day and night. Perhaps they were more keenly disappointed than the rest of us because we did not get everything asked for, but much progress for the good of the profession and humanity at large was accomplished. Considering that there were others whose programs failed to pass, we have every reason to be pleased, hopeful, and optimistic for the future.

"I want to add my personal word of appreciation for the splendid work done by Dr. Jeannette Dean-Throckmorton in administering the office of the Medical Department of the Iowa State Library. I am very sure that as this service is better understood, that more and more of our members will avail themselves of the great help this institution affords."

Doctor Rohlf also advocated the establishment of a students' loan fund to assist needy medical students.

OBITUARIES OF MAINE PHYSICIANS

The May issue of the *Maine Medical Journal* contains the following note by the Necrologist of the State Society:

(Continued on page 935—adv. xvii)

(*Continued from page 934—adv. xvi*)

"During the past year we have lost rather more members than usual, and largely from heart disease. They left us in a minute or in their sleep. Having already printed their careers in our columns, a reference list here follows, with the date of their deaths. Thus we salute them."

Then follows the names of twenty deceased members, with a brief characterization of each as follows:

"A young leader in Aroostook.
"Distinguished eye surgeon.
"The right-hand man of Portland's organist.
"Versatile country doctor.
"Man of mark in Penobscot medicine.
"Skillful physician.
"Beloved citizen and physician.
"Maine's first Medical Councilor.
"A universal favorite.
"State Medical Adviser in the Spanish War.
"Prominent surgeon in York County.
"Model county secretary.
"The man who ran the town.
"All-round practitioner.
"Skillful surgeon and staunch friend.
"Good physician and citizen.
"Pharmacist and physician.
"Good in emergencies.
"Famous neurologist, east and west.
"State Board of Health worker."

No modification necessary . . .

It is not necessary to further modify S.M.A. for normal full term infants, for the same reason that it is not necessary to modify breast milk - for S.M.A. contains the essential food elements in proper balance. Because of this close resemblance to breast milk, the very young infant can tolerate the fat as well as the other essential constituents of S.M.A. and it is possible to give it in the same strength to normal infants from birth to twelve months of age.

As the infant grows older, therefore, it is only necessary to increase the total amount of S.M.A. diluted according to directions.

Orange juice, of course, should be given the infant fed on S.M.A. just as it is the present practice to give it to breast fed infants, to supply an adequate amount of the anti-scorbutic vitamin "C".

POPULAR MEDICAL EDUCATION IN MICHIGAN

How popular medical education is carried on by the Medical Society of Kent County, Michigan, which includes the City of Grand Rapids, is told by Dr. E. B. Andersen, Chairman of the Public Health Committee, in the following item from the June issue of the Journal of the Michigan State Medical Society:

"We have inaugurated four projects. *One,* we have extended an invitation to both the Grand Rapids *Herald* and the Grand Rapids *Press* to send a reporter to all meetings of the Kent County Medical Society. In this connection we have also stated that when the meeting is a dinner meeting provision will be made for dinner for the reporter if he will let his presence be known. We have requested that the reporter covering our meetings interview the Chairman of the meeting before leaving in order to avoid misstatement and wrong interpretation of anything that is said in the meeting.

"*Two,* we have arranged with the American Medical Association to furnish both of the above-mentioned papers with the medical broadcast for the week in sufficient time to have them appear in the Sunday and Monday editions weekly.

"*Three,* through the courtesy of Mr. Frank Sparks, editor of the Grand Rapids *Herald,* we will publish in the magazine section of the Sunday edition, weekly, a public health article. These articles are to be written by members of our County Society and published under the authority of the Society by our committee. For the present these articles will be anonymous, but the newspapers are very anxious that the authors' names appear with the article. They explain this by the fact that the public is much more interested in reading anything if they know the writer. These articles are to be approximately one thousand words in length, written in popular language and dealing with some particular subject. The space required in the paper is the equivalent of one full column and is donated by the Grand Rapids *Herald* provided we agree to use as outlined.

"*Four,* several members of the Society have already agreed to cooperate in the matter of circularizing their own patients with pamphlets on public health. These pamphlets will be provided through the committee and will be of such size that they can be enclosed with statements on the first of the month. We expect to obtain these pamphlets from the biological and pharmaceutical houses without their names appearing on the same. All the cooperating doctors will be furnished with the same pamphlets at the same time."

CHIROPRACTOR SUIT IN TEXAS

The Texas State Journal of Medicine of June contains the following news item on the successful prosecution of a chiropractor for practicing medicine without a license:

"*The Brownsville Herald,* of May 3, advises that a $250.00 fine and a thirty-day jail sentence were assessed against W. S. Hamel, Brownsville chiropractor, charged with practicing medicine without a license, by a jury in the Cameron county court at law, May 1. It further states that the courtroom was filled with chiropractors and their attorneys who were anxious to see how the test case would be handled. The prosecution was handled by Martin Hall, Cameron county attorney. The defense attempted to prove that chiropractors did not practice medicine, but Judge E. T. Yates' definition of medicine in his charge to the jury included chiropractors. County Attorney Hall quickly brought out that Hamel gave treatments and charged for them and that he did not have a State license to practice medicine. He vigorously opposed expert testimony concerning chiropractors. The plaintiff is on trial for not having a State medical license; not for being a chiropractor, Hall said."

THE TREATMENT OF CHRONIC OSTEOMYELITIS WITH LIVE MAGGOTS

By FRANK S. CHILD, M.D., PORT JEFFERSON, N. Y., AND EDWARD F. ROBERTS, M.D., Ph.D., PEARL RIVER, N. Y.

The work of which this article is a report was done in the St. Charles Hospital for Crippled Children, Port Jefferson, the Mather Memorial Hospital, Port Jefferson, and the Lederle Laboratories, Inc., Pearl River, N. Y.—Editor's Note.

ABOUT three years ago the late Dr. William S. Baer began treating chronic osteomyelitis with disinfected maggots (1). Because of the difficulty in propagating the maggots and rendering them sterile, the treatment did not become available to the medical profession until December of 1930. At that time the Lederle Laboratories began producing disinfected maggots.

The literature on the use of disinfected maggots in the treatment of chronic osteomyelitis is very scant. The most complete statement of Dr. Baer's work, which we have found, is in his testimony before the Committee on World War Veterans' Legislation, House of Representatives (2). At this hearing Dr. Baer and his associate, Dr. Livingston, stated that over one hundred and twenty cases of osteomyelitis had been treated, of whom 98% were cured.

On another occasion we were informed by Dr Baer that 95% of his cases in children were cured and 85% in adults.

Baer and Livingston (2) reviewing the ancient and medieval literature state that Andrew Paro, 1510-1590 noted maggots in war wounds. as did also Benvenuto Cellini.

Larrey (3) mentions the beneficial effects of the larvæ of the blue fly in war wounds in Syria during the Egyptian Expedition.

After the discovery of antiseptics by Lister maggots came to be considered contaminators of wounds. It remained for Baer to rediscover the value of maggots, or as he termed them—viable antiseptics.

The difficulty of growing disinfected maggots is mentioned by Weil (4).

Surgical Preparation of the Bone: As a preliminary to the maggot treatment the diseased bone is freely opened with an osteotome and all necrotic bone thoroughly removed. Cloaca or bone sinuses are chiseled out so that the entire diseased portion is freely accessible to the maggots.

Our technic at this operation is a soap and water cleansing of the part. This is done the night before operation and again on the operating table. It must be remembered that maggots will not work in the presence of antiseptics.

The operative field is draped as for any operation, using sterile sheets and towels. Instruments are sterilized and sterile rubber gloves are worn. After thoroughly removing all sequestra the wound is packed with sterile vaseline gauze, and a pattern of the wound is cut from bandage gauze.

Implanting the Maggots: A cage is necessary to confine the maggots and this is prepared by cutting a piece of 80 mesh brass screening cloth to the pattern made from the bandage gauze. The edges of this screen are inserted between single strips of sponge rubber split longitudinally. The opposing surfaces of the sponge rubber are first coated with rubber cement and then sewed together with the screen margin between. The screen is sterilized in an autoclave and is then ready for use.

Forty-eight hours after the operation the packing is removed, gas anaesthesia usually being necessary. Strips of adhesive plaster, one inch wide, are placed on the skin all about the wound and flush with the wound edges. This is to protect the skin and prevent dermatitis. "Duo" adhesive is then painted on the adhesive plaster. This "Duo" is waterproof and more securely holds the cage in place and prevents the escape of maggots. Next, adhesive plaster the length of the cage is folded, adhesive surface out, and attached to the sponge rubber of the cage on the side which is to be against the wound. Everything is now ready for the maggots which are applied in the following manner.

Sterile normal saline solution is placed in the

bottle containing the maggots, and the bottle emptied onto a small piece of sterilized screening cloth through which the water drains, leaving the maggots on the screen. With a sterilized wooden tongue blade the maggots are very gently scraped in the wound. Some prefer to use fine mesh gauze or a spoon made with screening cloth. Any method will do so long as the maggots are not injured. The cage is immediately applied, and secured in place by wide strips of adhesive extending from the sponge rubber to the skin, and then by narrow strips of adhesive placed at intervals across the cage. The adhesive must be spaced wide enough apart so as to provide light, which drives the maggots deep into the wound, and also to provide air which is essential for their vitality.

The cage should be inspected daily, for the profuse discharge may loosen the adhesive and permit the escape of maggots. It is best to allow this discharge to drain through the screen. We have tried cutting trap doors and aspirating the liquid but we found that these openings made an easy exit for the maggots.

The maggots are left in the wound five days. Then the cage is removed and the maggots washed out with sterile normal saline solution. Maggots buried deep in the granulation tissue are removed with sterile thumb forceps. A new implantation of maggots may be made at once, after cleaning the skin, but usually we apply a dry dressing of parresine mesh and gauze and wait twenty-four hours. With each application of maggots a new pattern of the wound is made. This is because it is preferable to discard the old cage, and also because the wound rapidly becomes smaller.

With the first application of maggots we administer a prophylactic dose of tetanus antitoxin. Our only reason for doing so is that Baer reported tetanus in one of his early cases (Maggots not disinfected[3].)

Preparation of Maggots: The main problem involved in preparing maggots suitable for clinical application is the use of a disinfecting procedure that is bactericidal without being insecticidal. In early work attempts were made to disinfect the maggot itself but this soon proved impractical and attention was turned toward disinfection of the fly egg. The technique developed by Baer and Knight (immersion for 30 minutes in solution composed of $HgCl_2$ 1:1000, alcohol 25 per cent and HCl 0.5 per cent) and subsequently modified by the Bureau of Entomology, U. S. Department of Agriculture (immersion for 15 minutes in solution composed of one part $HgCl_2$ in 4,000 parts saline, alcohol 25 per cent, HCl ⅛ per cent) has been used for egg disinfection by most investigators, but in our hands the method did not give consistent germicidal action and the hatching of the eggs after disinfection was often considerably impaired. Accordingly attention was turned toward the development of a procedure which would result in a minimum of bacterial contaminations and as nearly as possible a 100 per cent hatch of the disinfected eggs. After extensive experimentation, the following technique was devised:

Fly eggs laid by the species Phormia regina and Lucilia sericata on either hog spleen or raw beef are removed by gently brushing off the clumps with the flat end of a tooth pick into a beaker of sterile distilled H_2O. The water should be at a temperature of 4° C to prevent hatching of the eggs before disinfection takes place.

The apparatus for disinfection consists of a covered Gooch crucible attached to a filter tube by means of a thin-walled rubber tubing collar. The crucible and cover are sterilized separately, the crucible containing a small piece of fine mesh cheesecloth placed over the perforations. A short piece of ordinary rubber tubing is connected with the lower end of the filter tube which, with collar tubing attached, is immersed in 3 per cent phenol when not in use. When the crucible, cover, and filter tube have been assembled, a pinch clamp is attached to the small-sized rubber tubing and the apparatus is ready for disinfection.

Approximately 1100-1200 eggs are transferred to the cheesecloth layer in the crucible and are rinsed several times with sterile distilled H_2O (temperature 4° C) to mechanically remove bacteria. The pinch clamp is tightened and the egg clumps are thoroughly disintegrated by gently agitating them in 3-4 cc. of a sodium hypochlorite solution yielding 0.5 per cent available chlorine. Complete separation of the clumps is effected in ½-1 minute, and is important in that it makes the whole surface of each egg available to the action of the disinfecting agent. After loosening the clamp, the eggs are thoroughly rinsed with sterile distilled H_2O to remove all traces of chlorine, the clamp is re-tightened, and a neutral solution containing 4 per cent formaldehyde added to fill up the crucible. The eggs are exposed to this disinfectant for 3 minutes, then the clamp is loosened, and the eggs are rinsed a third time with sterile distilled H_2O. All agents in the above procedure are used at a temperature of 4° C.

As soon as most of the fluid has drained off, the piece of cheesecloth holding the disinfected eggs is transferred with sterile forceps to a 2 oz. bottle containing about 4 cc. of a sterile semi-solid medium. The medium consists of 1 per cent agar, desiccated liver, and dried yeast. Experience has shown that poor hatching results if the cloth with eggs is dropped on the medium and therefore the bottom surface of the moist cloth is smoothed out so that it will adhere to the bottle wall.

The bottle is then placed in a hatching incubator (regulated for temperature, humidity, and ventilation with exclusion of light). Twenty-four

hours later hatching is completed and the tiny maggots are tested for sterility by inoculating duplicate sets of fermentation broth tubes for detecting aerobes and deep meat tubes for detecting anaerobes.

After sterility testing the bottle of maggots is returned to the incubator for another day of growth and then the bottle is transferred to the chill room (temperature 4° C) to await the results of the sterility tests. Each bottle is held for a 4-day reading on the sterility tests before it is shipped. On the average, the technique as described above results in 90 per cent hatches free from bacterial contamination. It must be remembered that each bottle is subjected to a 4-tube test and if only one of these tubes shows a contamination within 4 days after testing, it is not released. Moreover, all tests are actually held in the incubator 7 days as a check on the dependability of the sterilizing process. The hatch after disinfection varies between 90 and 100 per cent of the hatch observed from non-disinfected eggs, the fertility of the eggs being comparable.

The method of shipment consists in packing the bottle of maggots next to a can of natural ice which is then surrounded by a 4-5 inch layer of pulverized cork as insulation between the chilled maggots and the walls of the carton. Since the ice in the package and the type of medium in the bottle both serve to retard the growth of the maggots while retaining their viability, they remain during transit at approximately the same 2-day stage of growth at which they are shipped, and therefore may be left in the wound 5 days unless unfavorably affected by the wound secretions or lack of food. Upon arrival, a bottle of maggots may be kept in an icebox at 4° C. for a few days before implantation if necessary, but this is obviously not desirable since the maggots are perishable and cannot be stocked indefinitely. Such a procedure is certainly not feasible when a bottle remains more than two days in transportation. All shipments are sent special delivery to facilitate transportation.

Of no less importance than the problem of developing an effective disinfecting procedure is the proper breeding of flies to insure a constant supply of fertilized eggs. This involves attention to environmental factors such as temperature, humidity, and ventilation and more particularly to selectivity of strains in all the stages of the fly's life cycle. Another contributing factor is the choice of foods which supply protein and carbohydrate in forms readily assimilated by the larvæ and adult flies. If cognizance is taken of these requirements, one may be fairly well assured of constant and abundant laying of fertilized eggs by young and vigorous flies.

Case Reports: The following are the reported cases of chronic osteomyelitis treated by us by the implantation of disinfected fly larvæ.

Case No. 1

J. L., age 15, female. Onset of acute osteomyelitis July, 1929. Admitted to St. Charles Hospital for Crippled Children August 22, 1930. Diagnosis, chronic osteomyelitis. Involvement right femur. Osteotomy and Orr treatment instituted September 10, 1930.

First implantation of maggots December 9, 1930. Last implantation May 15, 1931. One month later scar was covered with epithelium, which was smooth and without indentations. Total implantations eighteen.

Case No. 2

E. M., age 10, male. Referred by Dr. Stanley P. Jones, Mattituck, Long Island. Admitted to St. Charles Hospital for Crippled Children January 10, 1931. He was transferred from the Mather Memorial Hospital where an osteotomy of the femur had been performed December 31, 1930, and the first implantation of maggots made January 2, 1931. This patient gave a history of having had meningitis November 14, 1930, a gram positive organism being recovered from the spinal fluid. Acute osteomyelitis was discovered December 8, 1930 and the right femur opened and drained, also the left tibia. At time of admission there was a dislocation of the right hip.

The last implantation of maggots was made May 23, 1931, there being a total of thirty implantations in two bones. The wound healed with a sinus due to fact that at operation all necrotic bone could not be removed because of pathological fracture through trochanter. X-Ray showed two small sequestra remaining. The patient is in excellent condition and after another osteotomy the maggot treatment will be continued.

Case No. 3

F. L., age 5, male. History of a giant cell sarcoma removed from tibia about three years ago Because of non-union bone grafting was attempted three times, all unsuccessful, and the last time bone became infected. Admitted to St. Charles Hospital for Crippled Children February 4, 1930. Diagnosis, chronic osteomyelitis of tibia, old fracture of tibia and fibula, and discharging sinus in leg. Leg was immobilized in long plaster spica until September 24, 1930 when, because of continued non-union, internal fixation by means of Sherman plate was done. January 17, 1931, there was still non-union and maggots were implanted. April 2, 1931, last implantation of maggots, total of eighteen. Plaster spica continued throughout treatment. Result, *x*-ray shows increased production of bone and there seems to be union. Spica not removed. Scar covered with smooth epithelium without indentation.

CASE No. 4

R. B., age 7, male. Admitted to St. Charles Hospital for Crippled Children September 5, 1930. Diagnosis, tuberculosis of right hip of about five years' duration: discharging sinus. January 21, 1931, with a probe in the sinus to indicate its position, an incision was made, laying open the sinus and exposing the hip joint, anteriorly. Wound packed with vaseline gauze. Six days later packing removed, without anaesthesia, and maggots implanted. Last implantation May 4, 1931, total of twenty-four. Result, wound covered with smooth epithelium, except for one small area: no sinus.

CASE No. 5

F. K., age 14, male. Onset of acute osteomyelitis July, 1928. Admitted to St. Charles Hospital for Crippled Children July 26, 1929, with history of having had several operations following compound fracture of tibia which was the cause of the osteomyelitis. Diagnosis, chronic osteomyelitis in tibia at site of old fracture, sinus with intermittent discharge. Usual preparatory osteotomy performed February 21, 1931. First implantation of maggots February 27, 1931. Last implantation April 28, 1931, total of fourteen. Result, wound completely covered with smooth epithelium and not indented.

CASE No. 6

M. H., age 10, male. Onset of acute osteomyelitis September, 1929. Admitted to St. Charles Hospital October 5, 1929, with history of having been treated for six weeks for typhoid fever.

Diagnosis, chronic osteomyelitis involving right femur, left tibia, right humerus, both iliac bones of the pelvis and spontaneous dislocation of the right hip. On admission all lesions were opened and drained, and after formation of sequestra the Orr treatment was instituted. Because of sinuses in right femur and left tibia these bones were opened March 9, 1931 and maggots implanted. Last implantation May 8, 1931, total of thirteen in two bones. Result, wound covered with epithelium which is smooth and not indented. *X*-ray showed sequestrum in distal end of right femur. This will be opened and maggots implanted.

CASE No. 7

Age 20, male. Admitted to Mather Memorial Hospital June 11, 1930, with history of having had a compound fracture of left tibia ten years ago.

During past ten years has had occasional discharge from sinus in the leg. On admission had temperature of 104° F. and severe pain in left leg. Onset six hours before admission.

Tibia was immediately opened thoroughly and packed with vaseline gauze. Patient discharged August 5, 1930. The wound was closed except for a small granulating area. The wound was dressed regularly at the office of one of us (F.S.C.) but failed to heal. January 6, 1931, the patient was readmitted to the Mather Memorial Hospital. Maggots were implanted on the ulcer but did not do satisfactory work and on January 17, 1931, the ulcer was curetted exposing necrotic bone beneath. This latter was removed, wound packed with vaseline gauze and six days later the packing removed under gas anaesthesia. Maggots were again implanted. The last implantation was May 25, 1931, total of twenty-six.

Result, June 20, 1931, wound now nearly covered with epithelium, the granulation tissue having a much healthier appearance than previously.

CASE No. 8

J. L., age 50, male. Referred by Dr. Grover A. Silliman of Sayville, Long Island.

Admitted to Mather Memorial Hospital December 8, 1930. Complaint, pain in right leg for past eighteen months and discharging sinus. Gives a history of having had acute osteomyelitis in right leg forty-one years ago. Treated in New York and Brooklyn hospitals.

December 9, 1930, osteotomy of tibia and packing with vaseline gauze. Six days later packing removed under gas anaesthesia and maggots implanted. After third implantation bone looked as clean as though it had been burnished. This patient frequently complained of numbness in the leg and foot while maggots were working. Last implantation March 2, 1931, total of fifteen.

May 15, 1931, patient reports that he works all day without discomfort and that he has walked as much as fifteen miles in a day. Wound entirely covered with smooth epithelium—very different from the original scar.

CASE No. 9

J. R., age 30, male. Admitted to Mather Memorial Hospital January 19, 1931. Gave a history of having had acute osteomyelitis twenty years ago in Germany where he had several operations. Did not give him any further trouble until eighteen months ago when he came to one of us (F.S.C.) because of pain in the left leg. At this time an osteotomy was done and Orr method instituted. He was discharged from the hospital apparently cured but returned one year later when another abscess was found in the tibia. This was treated as before and apparently cured.

The reason for the present admission was pain in the left leg. On January 20, 1931, the left tibia was opened the entire length and necrotic bone found near both epiphysis. Cavity packed with vaseline gauze and six days later gauze was removed under gas anaesthesia. Because of considerable oozing of blood, maggots could not be implanted until the next day.

During the maggot treatment the patient developed acute pharyngitis which was followed by cellulitis about the wound and inguinal adenitis on the same side. All the maggots died. Hot saline dressings were applied to the wound and after subsidence of the inflammation maggots were continued and worked satisfactorily. The

Figure 1

Case No. 10. After four implantations. Wound washed out and ready for adhesive

last implantation was April 10, 1931, total of fifteen.

June 15, wound is closed with smooth epithelium and patient working all day as gardener. He has no pain

CASE NO. 10

W. W., age 17, male. Admitted to Mather Memorial Hospital May 7, 1931, because of discharging sinus in right leg.

History: Received compound fracture of right tibia May 10, 1930, when knocked from motorcycle by collision. Bone plated by one of us (F.S.C.), good union resulting. After operation had several small sequestra discharge from wound and sinus persisted.

May 8, 1931, at operation small area of necrotic bone found near site of fracture. This was thoroughly curetted and packed with vaseline gauze, all unhealthy skin being removed at same time. Seven days later packing removed without anaesthesia and maggots implanted. June 15, 1931, last implantation of maggots, total of eight. Wound filled with granulation tissue, compact and healthy. New epithelium is fast closing over.

Discussion of the Cases: At the beginning of the treatment the patients are annoyed by the crawling sensation and by what some of them describe as the itching from the maggots. Occasionally we are obliged to give a mild sedative at night. As the treatment progresses and the patients note their rapid improvement they become accustomed to this irritation and rarely complain. An interval of twenty-four hours between implantations gives the patient a respite from this.

Frequently on the third or fourth day we have noted a rise in temperature to 102 or 103 degrees. The temperature returns to normal as soon as the

Figure 2

Case No. 10. Adhesive strips about wound. "Duo" adhesive is painted on outer surface of strips.

maggots are washed out. This fever has been noticed particularly when the discharge has been profuse and is due, we think, to insufficient drainage.

The effect on the wound is very remarkable. After the second or third implantation the bone has the appearance of having been bored out in the manner of a cylinder of an automobile engine.

Granulation tissue soon appears and is nearly always compact, rarely becoming exuberant. Later small pieces of sequestrum, loosened by the action of the maggots, appear and are easily removed without discomfort to the patient.

There is no purulent odor, and free pus is never apparent. On removing the cage preparatory to washing out the maggots there may be detected a faint briny odor which seems to be characteristic of the maggots.

Figure 3

Case No. 10. Cage ready for attachment. Note adhesive folded, face out, attached to sponge rubber strips.

Baer has stated that six to eight implantations were usually sufficient to effect a cure. We have found that in the majority of our cases this was not sufficient. The greatest number of implantations used was thirty. This was case No. 2 which was reopened and is now under treatment a second time. The tibia was cured but the healing in the femur seemed to be faster than the maggots were able to work.

The smallest number of implantations was eight. The average number has been about fifteen to eighteen. Time required to effect a cure has been eight weeks to six months.

One of our most interesting cases has been that of No. 3, a little boy with non-union of the tibia following complications after removal of a giant cell sarcoma. Following the maggot treatment there has been a definite growth of new bone and apparent union.

The maggot treatment is apparently beneficial in the treatment of tuberculous sinuses as demonstrated in Case 4.

Occasionally on removing the cage we have found all the maggots dead, although the wound was not filled with granulation tissue. In the succeeding implantations the maggots were alive and working. This is mentioned to show that dead maggots do not always indicate a cure.

Following the first implantation of maggots all patients receive a prophylactic dose of tetanus antitoxin. Although Baer had no cases of tetanus after using disinfected maggots we consider it a wise precaution.

Figure 4

Case No. 10. Maggots implanted. Cage securely fastened.

Summary

Nine cases of chronic osteomyelitis and one case of tuberculous sinus, a total of ten cases, have received the Baer treatment of maggots. Six of the patients were children and four adults.

Of the nine cases of osteomyelitis, eight have healed satisfactorily (an additional lesion in one will require treatment), and one will require an-

other operation and treatment. The tuberculous sinus has closed. That is, all lesions treated in the nine cases have healed with the exception of one. This one exception was due to failure to remove all necrotic bone because of pathological fracture.

Rise in temperature to 102 or 103 degrees on the fourth day of each implantation has been a frequent observation

Itching caused by the maggots has annoyed many of the patients at first but was easily controlled by sedatives at night

The odor of purulent discharge has been absent in every case.

The preparation of the bone by osteotomy is a surgical procedure and should not be undertaken by anyone not familiar with bone surgery.

It is the opinion of the authors that this is the most satisfactory treatment yet devised for the treatment of chronic osteomyelitis.

The authors wish to acknowledge their appreciation for the cooperation and many helpful suggestions of the following, Dr. Coburn A L Campbell, Resident Physician St Charles Hospital for Crippled Children Miss Margaret Bullowa, Miss Frances Clapp and Mr Stanley D Beard of Lederle Laboratories.

LIPIODOL INJECTION OF A DOUBLE UTERUS

By FRANCIS J. CERAVOLO, M.D., AND ISAAC LEVINE, M.D., BROOKLYN, N. Y.

Mrs. C. D., age 26, white, presented herself for examination because of an occasional dispaurenia. The family and past history was irrelevant. Menses began at the age of 14. The flow lasted for three to five days and was associated with a considerable amount of pain. Patient was married eighteen months ago. Coitus at times was associated with some dispaurenia. Contraceptive measures were employed until five months ago. At that time patient became pregnant The pregnancy was terminated by a miscarriage at the end of the third month.

Vaginal examination showed a bipartate vagina with the septum extending all the way back to the posterior vaginal wall. In each vaginal compartment a distinct and separate cervix was observed The cervix on the right side appeared to be more patulent than the cervix on the left. Because of the dispaurenia the patient was advised to have the septum removed. This was done by Dr W. B Anderson. Lipiodol injection of the uterus was done to determine whether or not we were dealing with a true didelphys A cannula was inserted in each cervix. The patient was highly neurotic and at the first session permitted us only to insert a cannula in the right cervix. Six cubic centimeters of lipiodol, Lafay, was injected into the right uterus The right uterus and tube were visualized At the second examination a cannula was inserted in the right and left cervix Six cubic centimeters of lipiodol, Lafay was injected into each uterus In spite of all precautions the injection of the right uterus on this occasion was incomplete because of the lack of co-operation on the part of the patient. The left uterus was completely filled and was visualized together with its tube.

This anomaly is the result of the failure of fusion of the two Mullerian ducts.

DEEP INTERFASCIAL INFECTION OF THE NECK*

By HERMAN J. BURMAN, NEW YORK, N. Y.

From the Laryngological Department of the New York Post Graduate Medical School and Hospital. Service of Dr. Charles J. Imperatori.

ABSCESS formation in the deeper structures of the neck, is one of the dread conditions requiring immediate and heroic measures.

When one considers the abundant vascularity of the neck, its limited confines containing very many important structures, and the very loose areolar tissue leading directly to the mediastium, it is obvious that here is an ideal culture medium for infection, once established. When, as a result of infection abscess formation occurs, the life of the patient is greatly endangered, unless it is recognized early and appropriate treatment immediately instituted.

Practically everyone who has written on this subject, has thought it necessary to go into a detailed description of the Deep Cervical Fascia, in order, so they say, to give the reader a better appreciation of the ease with which an abscess may spread to the mediastinum. I shall omit this, for it is evident, that one versed in the anatomy of the neck has nothing to gain from such a description, and the reader who is not so fortunate, can do no better than to refer to any of the standard text books of anatomy.

The vital structure of the neck from the standpoint of infection is of course the internal jugular vein. In the American literature the first cases are those reported by Goodman (1) and Mosher (2). There has also been reported by Hastings (3) a case of thrombosis of the superior thyroid vein, due to an abscess between the larynx and pharynx. Of immediate concern is the glottis. Pressure in the deep tissues of the neck inevitably results in edema of the glottis, narrowing the chink, which even normally is none too wide.

It is by way of the lymph vessels and glands draining the upper respiratory tract, and the loose connective tissue spaces intimately connected with them, that abscesses may descend into the neck and mediastium. The pus frequently extends along the side of the vascular sheath into the deeper structures and into the mediastinum, thus involving such vital organs as the heart and lungs.

Glogau (4) says that such infections are more frequent in childhood, because there is more lymph gland structure in the connective tissue spaces of the throat and neck.

In an excellent and comprehensive article, Shapiro (5) classifies deep cervical infections as phlegmonous and vascular. In the phlegmonous, which is the more common type of infection, the signs of local inflammation predominate. This is primarily a cellulitis, and in the majority of cases abscess formation occurs, resulting in swelling of the neck and fever. The swelling is usually noticeable before the end of the first week and is seen earliest in the submaxillary region. Extension downwards often takes place in a few days. The fever is noted soon after infection has occurred and is first apparent in the afternoon, frequently it is preceded by a chill. If the abscess has extended into the parapharyngeal space, irritation of the internal pterygoid muscle occurs with a resulting trismus; the slightest movement of the jaws being painful. Constantly the patient complains of pain in the throat and neck, not infrequently referred to the ears. Adenitis of the submaxillary and anterior cervical lymphnodes is of course always present but is generally not noticed, because of the diffuse swelling of the region.

The vascular form represents a true septicemia. Phlegmon may be absent, have preceded or accompany it. In connection with this type of infection, Shapiro quotes Shotmüller and Behzold as saying that bacteria cannot multiply in the living blood stream. There must be a collection of pus somewhere which continually or periodically discharges pathogenic bacteria into the circulation.

The most common causes of deep cervical infection in order of their frequency is given by Glogau (6) as Angina of the faucial tonsils following tonsillectomies, following phlegmon and erysipelas of the pharynx, following laryngeal phlegmon, following foreign bodies, as a secondary descending abscess.

The literature on the bacteriological study of this condition is rather meagre, but most writers are in accord, that the usual bacteria of the mouth are to be found either in pure culture or mixed with other organisms; that is to say pneumococcus, staphylococcus aureus, streptococcus hemolyticus and non hemolyticus, and the fusiform bacilli. McIntosh and Nichol (7) report a series of five cases in children. In two of the cases no specimen of the pus was cultured but in the other three cases in which it was done, pure cultures of non hemolytic streptococci were obtained.

Case History

A woman sixty years old, while eating her dinner, felt a piece of meat lodge in her throat. Violent efforts to expel this foreign body proving ineffectual, she called her family

* Read before the Lincoln Hospital Alumni Association, December 15, 1930.

physician He was unable to respond to the call, and the patient decided to go to one of the city hospitals

At the hospital emergency room the throat was examined and palpated for the foreign body without avail She decided to try again, and went to another hospital, where she was once again examined and the piece of meat not located At this second institution the intern who examined the patient had previously been applying a cast, for she stated, that he was wearing a pair of rubber gloves spotted with plaster and that he did not remove these gloves when palpating her throat

Discouraged, she returned home to await developments Although she had been told at both hospitals that there was no piece of meat lodged anywhere in her throat, and that the sensation of a foreign body was probably due to the irritation caused by swallowing an unusually large bolus, she insisted that it was still there

Three days later she was seen at home by her family physician At this time she complained of headache, backache, chills and fever, sore throat and dysphagia Any effort to swallow food was usually followed by its being regurgitated through the nose She also complained of a hypersecretion of mucus and drooling from the mouth

Physical Examination

The physical examination revealed her to be wan, pale, slightly cyanotic, and in evident distress The pupils were equal and reacted to light and distance The cornea were dry and there were no petechial spots seen There was a drooling of viscid saliva, and excoriation at the right angle of the mouth The heart sounds were normal but rapid, the pulse rate being 122 per minute The blood pressure 146/100 There was no edema of the extremities The lungs were clear but the respirations were labored and with an expiratory grunt The abdomen was soft and scaphoid The liver and spleen not palpable The tendon reflexes were exaggerated The skin was hot and moist The temperature 101 5 degrees

The mouth was opened with difficulty because of the pain it occasioned The mucosa of the pharynx was bright red and looked glazed The tonsils were large and reddened but showed no exudate

Indirect examination of the larynx disclosed the cords to be white and to approximate completely The ary-epiglottic folds were red and swollen, the edema on the right side being more marked The epiglottis was also edematous and there was definite bulging in the right pyriform fossa

Externally the neck appeared reddened, markedly indurated, and pitted on pressure The induration extended from the floor of the mouth down to the level of the sternal notch The region of the right side of the larynx was very tender to palpation

A diagnosis of descending deep interfascial infection of the neck was made

It was advised that the patient be hospitalized, and the family was apprised of the grave prognosis

She was examined at the New York Post Graduate Hospital by Dr Charles J Imperatori who confirmed the above facts and decided on immediate operation

Operation

Examination by direct laryngoscopy disclosed edema of the whole post cricoidal region of the larynx, and a bulging in the pyriform sinus low down near the cricoid

Oesophagoscopy showed the lower pharynx to be occluded by edema and a bulging of the mucous membrane above and below the crico pharyngeus There was no loss in the continuity of the mucosa

One end of a feeding tube was inserted into the stomach and the other end allowed to protrude through the nose

An incision was made along the anterior border of the sterno cleido mastoid on the right side, at about its middle third The incision was then lengthened through the superficial layer of the deep fascia and by blunt dissection the sheath of the great vessels was exposed The sternocleadomastoid was retracted laterally, the larynx mesially, and a large abscess at the side of the larynx was entered With a blunt haemostat the abscess cavity was widened and a large quantity of foul smelling pus was permitted to escape slowly A specimen of the pus was taken and cultured on blood agar plates and was subsequently reported to be a pure culture of streptococci, producing green colonies The wound bled only moderately The sheath of the vessels was not opened and, as there did not appear to be an extension downwards the mediastinum was not entered Two rubber drain tubes were inserted and the wound packed tightly with iodoform gauze

No foreign body was located although a diligent search was made

Throughout the operation the patient's color was good and the pulse maintained at 110 per minute

The first two days, pus was withdrawn through the rubber tube drains by gentle suction On the third day, and every day thereafter the wound was irrigated with Dakin's solution She was given a gargle of ten

minims of Dakin's solution to the glass of water because of the frequent expectoration of tenacious yellowish muco-pus. Liquid food was well taken through the feeding tube and retained. Despite the precaution of using vaseline to protect the skin, she complained of a burning sensation around the edges of the wound.

The temperature continued to range between 100 and 101 degrees, and the pulse was maintained at 100 per minute. There was a constant moderate diaphoreses. The drainage from the wound was considerable.

The fifth day post operative a slight persistent cough developed and the temperature rose to 102 degrees. The lungs were examined and found to be clear. A second oesophagoscopy was performed and a bulging as on the first examination was seen, but because of the free external drainage no further operative procedure was undertaken.

Following this there was an immediate increase in the amount of discharge, which in the next few days gradually diminished. Her general condition improved, the pain in the throat ceased. The feeding tube was removed and soft diet ordered. Twenty two days after admission she was discharged from the hospital, and except for a considerable loss of weight, in fair physical condition.

Comment

In the management of such a case the question always arises as to how radical the treatment should be. Practically every surgeon who has been confronted with this condition is agreed that emergency measures are imperative. The external operation is in the vast majority of instances the method of choice, and should be done always when the abscess points externally. It is also indicated when the symptoms of septicemia are increasing even though there is no bulging in the pyriform fossa; also if no drainage or remission of symptoms has taken place within forty eight hours after incision through the fossa; or if the external swelling and symptoms of absorption are progressing even though the abscess is draining through the pyriform fossa.

The line of incision as indicated, is along the anterior border of the sternoclaedomastoid muscle, but Keifer (8) in discussing this subject says that this landmark is infrequently available because of the edema of the region. He makes the incision well forward in the neck from the tip of the mastoid to the sternum. He warns against using gauze drains because of the frequency of hemorrhage, and therefore prefers employing rubber tubing for this purpose.

Apropos bleeding from the site of operation, it is well to remember that the pus should be evacuated very slowly; there have been cases reported where sudden death occurred as the result of its too rapid withdrawal. The theory is that these deaths are due to vagus inhibition.

Glogau who was America's most enthusiastic writer on the subject of deep cervical abscess advocated and practiced the so called Marschik's prophylactic mediastonotomy. This consists of opening the anterior and the posterior mediastinum and sealing them off with gauze, so as to form adhesions. Others do not however resort to this procedure unless there is a definite mediastinitis and any attempt to improve on that by breaking down barriers is something that most surgeons are avoiding. Sautter (11) objects to the procedure also on the ground that extension into the mediastinum is rare, and that if it does occur, it can readily be diagnosed by the Roentgen ray.

In the case above reported the etiology is not definitely established but is seems reasonable to conclude that it was due to an infection secondary to instrumentation, in an attempt to remove a foreign body. Furstenberg (12) relates an interesting experience which demonstrates the usual route of infection in such cases. He was attempting to inject lipiodol by means of a curved trocar into the larynx of a child aged six. Failing to penetrate the cricothyroid membrane the point of the instrument tipped over the cricoid cartilage, and came to lie somewhere to one side of the trachea. About 5cc of the opaque oil were injected before the accident was discovered. The course of the injected oil through the visceral space into the posterior mediastinum was clearly demonstrated by a stereoscopic plate.

To illustrate the results of improper instrumentation he quotes a case from the experience of Dr. Charles J. Imperatori—A woman fifty year old whose complaint was dysphagia was brought to the hospital. On oesophagoscopy Dr. Imperatori confirmed a roentgen diagnosis of diverticulum of the lower part of the oesophagus, but in addition he saw a distinct band-like stricture just anterior to the cardia. The patient died two days later and the autopsy revealed an empyema due to an oesophageal perforation high up in the small pouch of the dilated oesophagus. The physician who had referred the case to the hospital, later admitted to having unsuccessfully attempted to pass a bougie, probably causing the perforation.

Anaesthesia in operation for deep cervical abscess is rarely written about, and yet, it is

of extreme importance because there is always embarrassment of the respiration due to the edema of the glottis

Local infiltration would seem to be the safest procedure but where children or highly nervous adults are concerned, it may not be the most efficient kind of anaesthesia In discussing this matter with Dr T Drysdale Buchanan he gave it as his opinion that local infiltration in neck operations, often sets up dangerous reflexes by direct irritation For that reason he prefers giving a general anaesthetic

When a general anaesthetic is to be employed it is obvious that the choice should be in favor of those least depressing to the respiration or irritating the respiratory mucosa, which practically narrows the field down to gas oxygen Many surgeons employ the intratracheal method but the objection to this, is the irritation and trauma produced

It would seem that here is a condition ideally suited to the use of the so called basal anaesthetics The greatest objection to them is that they are not reversible, for once absorbed, elimination is slow and no measure will effectively retard their depressing action Avertin is now employed in head surgery by a number of surgeons who are quite enthusiastic about it There have however been reported a number of deaths These deaths have been generally attributed to its toxic effect on the liver

Proponents for the use of Avertin stress the fact that even when administered in full dose the pharyngeal reflex is not abolished, thus serving as a guard over the larynx to prevent the entrance of extraneous material If the pharynx and larynx have been cocainized, sufficient time should elapse prior to the operation to permit the return of this reflex

Conclusions

1 Instrumentation for a foreign body in the larynx, except by direct laryngoscopy is a dangerous procedure

2 If search is made for a foreign body the utmost precaution as to cleanliness should be observed

3 Operation is indicated if there is edema or bulging in the larynx, or if there are general symptoms of septicemia

4 The external route is preferable because it offers the most rapid and more certain way of insuring drainage

5 Prophylactic mediastinotomy should not be done routinely, because mediastinitis is infrequent and can be diagnosed by Roentgen ray if it does occur

6 A well managed general anaesthetic is safest

7 Basal anaesthesia should not be administered soon after cocainization of the larynx

8 Deep interfascial infection of the neck is a grave surgical condition, and any experience with it warrants being reported

A FLUOROSCOPIC MIRROR

By JACOB SARNOFF, M D, BROOKLYN, N Y

IN a recent article Dr Crile stated that the future of medicine will be more in the form of prevention than in the form of the cure of disease The average individual will be so educated and well informed that he will, to a certain extent, diagnose and take the necessary steps toward the cure of his ailment To what extent this will become true, only the future can tell Nevertheless even to day, the tendency for the lay public is to acquire additional knowledge and understanding of human ailments They are becoming more inquisitive and demand of the physician facts and findings in diagnosis which help them to arrive at a conclusion Questions such as these are frequently encountered "What

is my blood pressure, Doctor? What does my blood examination show? What are the urinary findings? Have I diabetes or kidney trouble?" Likewise not only do they ask for the X-Ray findings, but they are also anxious to see the films; whether it be a fracture, a dislocation, a foreign body or gallstones. The conventional secrecy and mystery surrounding human ailments are being more and more discarded,—Seeing is believing!

The purpose of this article is to present in a simple manner the feasibility of reflecting the image from the fluoroscopic screen on to a mirror, which can be seen to advantage by the patient as well as the radiologist and an audience of any size. (Fig. 1) What prompted the writer, whose field is far removed from X-Ray, to suggest the idea was a personal fluoroscopic examination. On this occasion, his colleague dictated the negative findings to his secretary. His curiosity arose as to why he himself could not observe the findings, and then the idea occurred to the writer to use a

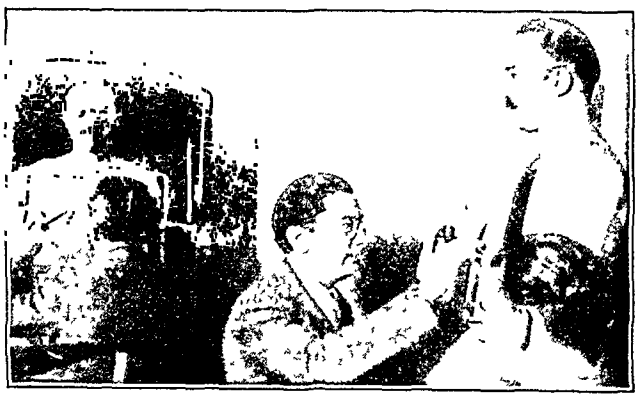

FIGURE 1

Radiologist observes findings at screen, while patient and observer view same through mirror.

mirror to reflect the image from the fluoroscopic screen. This was demonstrated by the writer in the X-Ray laboratory of the United Israel-Zion Hospital on March 8, 1931 to the satisfaction of quite an audience composed of internes, members of the Medical Staff, and the attending radiologist.

The mechanical arrangment is very simple. The mirror may be attached on to a swivel in the fluoroscopic room so that the image can be reflected in any direction without effort. This arrangment of the mirror, however, can well be left to the discretion of those furnishing the X-ray equipment.

What are its possibilities and advantages? 1, Quite often during a fluoroscopy the patient is curious and even doubtful as to what is really accomplished by such an examination. He has to be content with the Doctor's explanation and findings. However he would be much more impressed and his fears allayed if in addition to what the Doctor tells him, he himself could visualize these findings. Imagine a patient following the course of the bismuth through the oesophagus, stomach, and intestines, and at the same time be assured by the physician that no abnormalities such as malignancy, are present. How convincing it would be to the patient. It would certainly be more conducive to a proper appreciation of such an examination by the patient and would also justly popularize this useful laboratory diagnostic aid.

When this paper was first presented at the Williamsburgh Medical Society on March 9, 1931, one of the participants in the discussion remarked that it would not be feasible for the patient to view such fluoroscopies, for fear that he might encounter a condition of which he should not be informed, such as cancer. For that matter it is not feasible even to tell the patient of such findings. The physician is endowed with enough discretionary judgment to show the patient only those facts which would be helpful. The above comment thus refuted, the idea created such a favorable impression that a number of my colleagues have since fitted their Fluoroscopes with such a mirror, to their great satisfaction.

2. It would facilitate the demonstration as well as the teaching of fluoroscopy. A large group of students and observers can be comfortably seated and yet view the findings without the unpleasant and awkward crowding around the patient, radiologist and screen. With the aid of lenses, the image may be magnified if so desired. Also part of the view which has no bearing and which may be confusing in the examination may be eliminated by the mere adjustment of the mirror.

3. The reflectoscope may be so constructed and arranged that the radiologist, as well as the audience, in many instances, may view the findings in another room quite a distance away from the fluoroscopic machine, thus preventing undue exposure to the rays.

The writer, whose endeavors are in the field of Surgery, hopes that he will be pardoned by radiologists for trespassing on their territory. It was mere personal curiosity on his part that prompted the idea, and he will now leave it to them for their practical application and improvement.

COMMON ERRORS IN DIAGNOSIS OF HEART DISEASE*

By LOUIS H. SIGLER, M.D., BROOKLYN, N. Y.

MOST errors in cardiac diagnosis result from one of the following conditions: 1. Improper understanding of the normal variations in the structure and function of the heart. 2. Lack of appreciation of the relationship between other bodily structural and functional abnormalities and this organ. 3. Improper conception of the underlying pathology in any form of heart disease, and the use of terms purporting to convey an idea of pathologic changes, the existence of which cannot be proven clinically, and are only too often disproved on the post mortem table.

ERRORS ARISING FROM A MISUNDERSTANDING OF THE NORMAL

Size and Shape: We very often consider a heart to be diseased when its size and shape do not conform to a preconceived idea of normality.

We fail to realize that we have no definite standard of normality, and that the "size and shape of the normal heart," to put it in Köhler's words, "are as different in different individuals as the size and form of the nose." One must always associate size and shape with other clinical manifestations of heart disease, if any, to arrive at a conclusion if a given heart is pathological. We often find hearts which are perfectly normal in appearance that are the seat of grave myocardial disease. On the other hand, an apparent enlargement, displacement or disfigurement of the heart may occur without any structural or functional pathology.

Rate and Rhythm: What is said of size and shape may also be said of rate and rhythm. Although the established normal rate at rest is 72 to 90 beats per minute, we very often find cases where the rate is 40 to 60, or in exceptional cases even less, with no pathology underlying it. In rates of less than 60, however, we must always rule out heart block. This can be done clinically by making the patient exercise, when the rate will go up in cases of simple bradycardia. The electrocardiogram is the surest way of checking up.

Disturbances in rhythm are more frequent sources of error in diagnosis. Simple sinus arrhythmia, and premature contractions, which in the great majority of children and the earlier adult life have no pathologic significance if unassociated with other manifestations of heart disease, are very often considered to indicate such disease. This is especially true if an occasional murmur is heard in addition.

The Murmur: This is by far, the greatest source of error in cardiac diagnosis. Many a false conception is formed because of its presence. In a great many cases the murmur has no pathologic significance. The physical requisites for murmur production, namely, the passing of fluid from or through a narrowed passage suddenly into a wider cavity is present in any normal heart with its narrowing at the valvular regions and comparatively widened vessels in which the blood enters. That no murmurs occur in the average normal heart is, according to Dr. Thayer, due to a wonderful adoptation of the aorta and ventricle, representing a single tube, and to the fact that the viscocity of the blood prevents it. I feel that we may make it a rule that any murmur not associated with any cardiac enlargement or definite change in configuration of the heart, is to be considered to be of no pathologic significance, and should be disregarded. Exception to this rule are murmurs heard in some forms of congenital abnormalities of the heart where there may not be any enlargement. The harshness of such murmurs, however, and their large area of transmission together with the fact that they were heard from early infancy, will easily differentiate these from functional murmurs.

IMPROPER CORRELATION OF DISEASE ELSEWHERE AND HEART REACTION

Constitutional and local organic disturbances elsewhere in the body will always produce more or less reaction upon the heart. In some cases the heart reaction is the outstanding feature, and leads to an erroneous diagnosis of heart disease. In all these cases the heart may be perfectly normal structurally, but merely reacts abnormally to abnormal stimuli. If it becomes affected secondarily, it is the primary factor which has to be treated to relieve the heart, not the heart itself.

The usual conditions leading to abnormal cardiac action and thus to an erroneous idea of heart disease are the various reflex, toxic and infectious states of the body.

Reflex Factors: Disease or abnormalities of the pelvic organs, gall-bladder, gastrointestinal tract and the nervous system may set up reflex disturbances of the heart which are mistaken for primary heart disease. The commonest manifestations are tachycardia, bradycardia, vagal arrhythmia, and premature contractions. An interesting example of this type is the case of a boy nine years old who sustained a fracture of his skull and developed a secondary brain abscess. The surgeon in charge questioned the advisability of operation fearing that the heart could not stand it. The patient presented marked bradycardia, rate about 38, marked sinus arrhythmia and frequent premature contractions, interpolated, so that there were periods of over three seconds when the heart would stop. From the behavior

*Read before the Harbor Hospital Staff Conference, May 6, 1931.

of the heart one might have thought that it was the seat of organic disease. It pointed more, however, to a reflex vagal disturbance due to intracerebral pressure. When the skull was trephined and considerable pus vacated, the heart became quite regular and the rate went up to 100.

Examples of milder grades of reflex cardiac disturbances are met with in daily practice, and one must be a trained judge not to condemn the heart for disturbances existing elsewhere. In many cases the seat of disturbance may not be discoverable, and disease of the heart itself must then be very carefully ruled out, by clinical and electrocardiographic study.

Toxic Factors: Various toxic states of the body will result in some form of abnormality of cardiac action, and, if persistent, may eventually lead to structural cardiac pathology. It is important, therefore, from a therapeutic viewpoint, to recognize early the cause of the heart disturbance, to make sure that this organ is not the seat of disease.

The most notable example of abnormal cardiac action in response to toxicity is the thyrotoxic state, where we may get marked tachycardia, simple or even paroxysmal, extrasystoles, fibrillation and flutter. Only careful investigation will avoid error in diagnosis in many of these cases, for this toxic state may exist at times with no classic findings such as exophthalmos, enlarged thyroid and tremors of the fingers. A basal metabolic rate determination will often clear up an otherwise obscure abnormal cardiac action.

Acute Infections: Any acute infectious disease may be associated by cardiac manifestations which at times alarm the physician, and make him direct his treatment to the heart. In the great majority of cases the heart is not the seat of disease but merely reacts to an abnormal constitutional state. In spite of this generally known fact, and because of the peculiar association in the minds of the physician of heart and digitalis, we are still utilizing quantities of the drug in our therapy of infectious diseases. The everlasting fight is still going on in the ranks over the value of digitalis in pneumonia, with authoritative pros and cons. Probably in the majority of infectious diseases the heart action will not be modified in any manner except in a deleterious way to the use of any drug directed towards its treatment. If the infectious disease is of a severe character, overwhelming the resistance of the individual, the patient will die in spite of and partly because of treatment of the heart. If on the other hand the individual's resistance has the upper hand, he will recover unless that organ has been overtreated. Paroxysmal tachycardia, auricular flutter and fibrillation, associating acute infections, do demand active treatment, however.

ERRORS ARISING FROM IMPROPER CONCEPTION OF CARDIAC PATHOLOGY

Nomenclature: The universal use in the profession of the terms "Chronic Myocarditis," "Chronic Endocarditis" and "Angina Pectoris" to describe something abnormal heard over the heart, or something complained of by the patient, is evidence of the general misunderstanding and misconception of heart disease. In looking over vital statistics records, one is amazed at the number of deaths attributed to chronic myocarditis, endocarditis and angina pectoris. If all these cases would come to autopsy, probably 80 per cent would not show any evidence of myocarditis active endocarditis and certainly no uniform pathology for the symptomatology characterized as angina pectoris.

If we consider myocarditis to designate an active inflammatory state of the heart muscle, as the term expresses it, we must have clinical evidence of its presence. The evidence should include fever, leucocytosis, progressive heart failure, various arrhythmias, and definite electrocardiographic findings of progressive myocardial involvement. Above all, some etiologic factor must be present at the time the myocarditis is suspected. The most common etiologic factor is the rheumatic virus. Less common are the various forms of sepsis.

The term "Chronic Myocarditis" would imply merely the continuance of an *active* myocarditis over a long period of time. The etiologic factor must be present and continuous, however, and clinical manifestations of an active inflammation must exist. As the term is generally used, it covers a multitude of sins. All forms of myocardial degeneration, the fibrotic heart, and the anatomically normal heart showing disturbances in rate and rhythm for reasons described above, are thrown into one sack, decorated with a fancy label, and considered a diagnostic feat accomplished.

What is said of chronic myocarditis is equally true of "Chronic Endocarditis." Chronic cardiovalvular disease of long standing with absolutely no evidence of fresh activity is labeled "Chronic Endocarditis." Are we to consider a scar resulting from an old infection or burn, an active inflammatory condition?

A few words about angina pectoris. Volumes have been written on this time-worn term, all of which are repetitions and fancies. The profession generally does not seem to have a clear idea of its meaning. It is considered to be a disease by some and a syndrome by others. That it is not a disease is evidenced by the fact that it has no uniform etiology, pathology, and symptomatology. To explain the various manifestations, terms such as "Pseudo-Angina," "Angina Sans Dolores," "Angina Decubitus" and "Angina of Effort" have been introduced, which further add to the misconception of the condition. The term

"Angina Pectoris" should be entirely discarded from medical literature, as meaning nothing. If we are to express a painful state of the heart associated with a choking sensation and strangulation, such descriptions should be used as symptoms, whenever such symptoms exist. To enter angina pectoris as the sole diagnosis is to admit ignorance of an existing underlying pathologic condition. At best it should be only a part of the cardiac diagnosis, the etiologic, anatomic, other physiologic and functional diagnosis are to embrace the main diagnostic features of the case, to give us a comprehensive idea of what is going on in the heart.

To summarize, this paper points out certain errors in cardiac diagnosis, as follows:

1. Errors arising from a misunderstanding of the normal size, shape, rate and rhythm of the heart, and non-pathologic murmurs;

2. Errors arising from an improper correlation of disease elsewhere and heart reaction. Of these we have the reflex, toxic and infectious states reacting upon the heart;

3. Errors arising from an improper conception of cardiac pathology, and the too frequently used and misapplied terms chronic myocarditis, chronic endocarditis and angina pectoris.

THE SINUSOIDAL CURRENT IN CHRONIC GONORRHEA OF THE MALE

By HAROLD NEIFELD, M.D., BROOKLYN, N. Y.

FOR the past several years gonorrhea in the male, both acute and chronic, has been treated with the electrical modalities. Of these, diathermy is the most effective; and yet under this treatment many cases of urethritis persist with a chronic discharge or shreds. It is in these cases that the sinusoidal current can be used successfully. A twenty minute application of ten to eighteen milliamperes three times weekly has proved valuable. In an occasional obstinate gonorrhea, the surging current, by its more vigorous reaction is found to be more beneficial than the sinusoidal current alone.

The value of the sinusoidal current depends upon its accurate application to the focus of infection with the proper electrodes. For this purpose the two-glass test is a simple, accurate enough method. If the first glass alone is cloudy or alone contains shreds we know that the chronic infection is limited to the anterior urethra. In such a case the penis is wrapped in moistened cotton, and electrodes are applied over this so as to include the urethra. The current is gradually turned on till the patient experiences a drawing feeling, or a feeling of waves. Should the case show a clouding of both glasses, one electrode is placed in the rectum so as to include the prostate.

The rational of the treatment is clear. According to Granger,* "The sinusoidal current is an excellent stimulant for unstriated muscle. Hence, it is useful in treating intestines, oesophagus or uterus, causing physiological contractions. Under the fluoroscope, after a barium meal, the intestines show (with this current) an increased peristalsis. Some indications for its use are atonic constipation, enlarged prostate where the sine waves will take the place of prostatic massage."

The male genital tract is admirably suited histologically for the treatment with the sinusoidal current. Between the visceral portion of the tunica vaginalis and the transversalis fascia of the testis lies the internal cremasteric muscle, a layer of unstriated muscle fibers. The vas efferentia near the epididymis contains endothelial cells resembling non-striated muscle cells; while the epididymis and the seminal vesicles have outer longitudinal and inner circular smooth muscle layers. The vas deferens has an involuntary muscle structure consisting of a middle circular and an outer and in inner longitudinal layer. The ejaculatory ducts contain a poorly developed inner circular layer, but a well-developed longitudinal layer of non-striated muscle, which is continuous with that of the prostate's capsule. The external envelope of the corpus spongiosum of the penis is formed partly of unstriped muscle tissue, and a layer of the same tissue immediately surrounds the canal of the urethra.

The sinusoidal current through its ability to contract smooth muscle stimulates the involuntary musculature of the genital tract, producing an emptying of the prostate, seminal vesicles, glands of "Littre" of the urethra, etc., with an improvement or cure of subjective and objective symptoms.

* Physical Therapeutic Technique—By F B. Granger, p. 64.

August 1, 1931

THE GRIEVANCE COMMITTEE

By HAROLD RYPINS, M.D., EXECUTIVE SECRETARY, STATE DEPARTMENT OF EDUCATION, ALBANY, N. Y.

THE Committee on Grievances of the New York State Department of Education, established under sections 1264-5 of the Practice of Medicine Act, has now been functioning for four years. As originally designed by its sponsors, its primary object was to provide a legally constituted body to protect the public by disciplining members of the medical profession who were guilty of improper practice. While the results accomplished by the Grievance Committee during this four-year period show that the original object for which it was designed is being accomplished, the Committee's experience indicates that it is accomplishing two other functions as well, first, the protection of the medical profession itself against unfounded charges, and second, the raising of the standards of professional practice.

To date the Committee has received 163 complaints against licensed physicians. Of these, 65 have been dismissed by the Executive Secretary on the grounds that the complaints alleged did not come within the legal purview of the Committee, and it is significant that so far as can be determined, not one of these sixty-five complaints has ever been brought before any other tribunal. In other words, the fact that without expense a citizen can place a complaint against a physician before a legally constituted professional tribunal, even though he is advised that he has no proper grounds for such complaint, is sufficient satisfaction to forestall a large number of malpractice suits.

In these cases the Grievance Committee acts as a safety valve for disgruntled patients, and has undoubtedly saved many members of the profession from unpleasant newspaper notoriety and the expense of defending unwarranted malpractice actions.

Perhaps the best work of the Grievance Committee is accomplished in informal hearings before a sub-committee of three members, at which both the complainant and the physician complained against are permitted to tell their side of the story without the necessity of a formal trial. Although the law does not require a physician to appear before the Committee unless he has been served formally in writing, the standing of the Committee is evidenced by the fact that not a single physician requested to appear at these informal hearings, nor any lawyer, has ever intimated any unwillingness to attend.

Of the 58 cases disposed of informally, approximately half have been cases in which, after hearing both sides, the sub-committee concluded that the conduct of the accused physician had been proper, and that there was no just cause for a formal trial. The other half have been cases in which there was a certain amount of evidence that the physician had either acted improperly, or had practiced too close to the borderlines of unethical conduct. It has been the policy of the Committee in these cases to give the defendant physician a serious warning and an admonition to improve his professional conduct. It is gratifying to note that, with a very small number of exceptions, it has not been necessary to recall any of these admonished physicians on later charges. There is no doubt that this method of handling physicians guilty of questionable practice has had an excellent effect upon not only the physicians directly involved but the profession as a whole; and this has been accomplished without publicity, or depriving the physician of any of his rights, in all cases in which such procedure is justified.

Only 17 cases have been referred to the Board of Regents; and with the excepton of one case, where the Grievance Committee recommended six months' suspension and the Board of Regents dismissed the charges, the recommendations of the Grievance Committee have been sustained by the Board of Regents.

In all, eight physicians' licenses have been revoked—two for attempted abortion; two for aiding and abetting illegal practitioners; two for fraud and deceit in practice; one for violation of the narcotic law; and one because of insanity. One phpsician's license was suspended for one year because of his offering to commit an abortion; and another for six months for association with an unlicensed practitioner. Four physicians have been formally censured and reprimanded by the Committee—one for improper advertising; four for association with illegal practitioners; and one for fraud and deceit in practice.

In additon, the Grievance Committee is authorized to arbitrate disputes between physicians, and between physicians and patients, and has successfully completed several such arbitrations.

The work of the Grievance Committee entails a sacrifice of much time and energy by its members, for which they receive no compensation whatsoever. They are accomplishing benefits both to the public and to the medical profession, and their work is now well

COMPLAINTS AGAINST LICENSED PHYSICIANS CONSIDERED FROM SEPTEMBER, 1928 TO JUNE, 1931

established upon a firm basis. As a result of their work, similar disciplinary bodies will shortly be started in several neighboring states.

CONTRIBUTIONS OF MEDICAL AND OTHER SCIENCES

By JOSEPH H. GETTINGER, M.D., BRONX, N. Y.

The Presidential Address at the Annual Meeting of the Bronx County Medical Society, June 17, 1931

THE political, social and economic history of mankind presents a vast panorama which unfurls before our eyes the records of noble endeavor, magnificent achievements, supreme sacrifices, as well as heinous atrocities, cold-blooded cruelties and merciless outrages. We are fascinated by its romance, thrilled by its climaxes and stand aghast at its tragedies. At one time we see man smothered by his unbridled desires and ambitions and dragged down by the gravity of the lowest instincts. At another we find him majestically soaring to heavenly altitudes impelled by the noblest impulses of self-sacrifice.

The scientific history of man presents no such diversity in its development and no such spectacularity in its growth. Its progress was slow and even monotonous, moving with a deliberate and rhythmic stride. But this stride carried with it the grandeur of enlightenment, the magnificence of truth. The rhythmic regularity like that of the tide brought the drift of noble thought to the banks of knowledge; its ebb carrying the wreckage of superstition and darkness into the abyss of the past.

The history of science presents an illustrious array of noble characters, identified with a wondrous ideality for creation and construction, continually making transitions from one set of fundamental entities and principles to another, ever thinking to introduce a rational order into the universe, each having added a stone to the great mosaic of learning. They not only made us heirs to the accumulated wisdom and experiences of past centuries, but through their ingenuity have added many essentials to our necessities, comforts and even to our luxuries. Their acts and words terminated epochs and inaugurated eras. The automobile, airplane, the cinema, wireless telegraphy and telephony, radio and television —all these landmarks of progress and civilization would have been still the hidden secrets of mute nature were it not for their scientific efforts.

The political economic history of the world presents no such personnel. The ambition and aim of the actors ever were the concentration of power, political advantages, military exploitations, and last, but not least, the accumulation of wealth. And lacking the ideality of true benefaction, their achievements were transitory and could not withstand the changing storms of time. Look upon Assyria, Babylon and Persia rising to their zenith, pouring forth their vast hordes, and then sinking again into oblivion. Greece with her chiseled temples crowning a thousand hills, her genius

endowing the world. What became of her? Rome rose to supreme grandeur, her army invincible, her law unchallenged until, under the fever of pomp and extravagance, she sank into decay. Nero, who ran the gamut of all that is atrocious and made the Romans minister to his atrocities; Alexander the Great who destroyed empires, vanquished nations, and, in one of his debauches, lamented the fact that there were no more worlds to conquer; Napoleon with his checkered career of rise and fall, suffocating nations by the dust of his marching armies; they all belong to the political history which drenched humanity in tears and blood.

In contrast with the warriors, Aristotle, Copernicus, Galileo, Newton, Darwin, Haeckel, Einstein, Milliken, Michelson, belong to the history of constructive science. The experiments and research of these savants were not devoted only to the fact-finding in the immeasurable vastitudes of space or in the imponderable littleness of the atom, concerned only with their scientific deductions, but their vision encompassed other fields and gave color to many sides of human life. This was true of the great innovations of thought in the past. The demonstrations of Galileo shook the religious world of his time, fundamentally changed Man's ideas of his relations to nature and to society, and made such a scheme of thought as we find in Dante seem suddenly antique and quaint. Newton's mechanics affected the structure of religion, society, and perhaps above all of politics. As for Darwin, we are still in the midst of the sweeping currents of change which the evolutionary doctrine set in motion. It is impossible as yet to predict the forms in which the ideas of relativity, which only the expert few can now understand, will affect thought and society; but the effects will occur and they will ultimately be far-reaching. And even our late venerable Michelson, though his concern and devotion were aimed at the objective of pure science, and whether it was the velocity of light which he strove to confirm by experiment, or whether it was in the infinitely small sphere of a molecular orbit that he sought new knowledge, his searchings and his findings alike led the average man to a deeper appreciation of the profound mysteries of living, exalted by a vision of the immensities.

The story of the triumphs of modern science is one of which man may be proud indeed. Every problem solved opened the door leading toward a mansion of more intricate problems. The problem of the ion touches the problem of the atom; the problem of the atom is associated with the problem of a planet; and the problem of a planet opens the way into the problem of the universe. The idea of evolution has formed the background of all sciences. The solar system, the earth, the mountain ranges and the great deeps, the rocks and crystals, the plants and animals, man himself and his social institutions—all must be seen as the outcome of a long process of transitional changes. Evolution has fashioned our mode of historical analysis and has taught us that, from the nebula to the social system, the present is the child of the past and the parent of the future.

Medicine, while its origin must have been contemporaneous with the origin of civilization, for us the history of medicine begins with the written history of events. Its earliest period is enveloped in profound obscurity, and so mingled with myth and fable as to be very uncertain. It embraces an indefinite time, during which medicine was not a science but an undigested collection of experimental notions, vaguely described, disfigured by tradition, and often made inutile by superstition and ignorance. Among the earliest records of probable authenticity are perhaps the Scriptures, from which may be gathered here and there a fair notion of Egyptian knowledge and practice. Centuries have since passed, and from the empty dawn of this maze has arisen a mighty institution whose arsenals are now filled with the ammunition of physics, chemistry, biology, physiology, pathology and allied sciences, to fight disease, to ameliorate pain and suffering, to prolong life. Medicine today is more concerned with prophylaxis, that is, with the prevention of disease, than it is with its cure, thus realizing the truism of "An ounce of prevention is worth a pound of cure."

Modern medicine does not only seek to lessen mortality by properly piloting man through the dangerous periods of growth and development, but it also anticipates the morbidity and infirmities so commonly incidental to old age. Medicine has made more progress within the last three decades than it did in centuries before. In fact, so torrential became the flood of its knowledge that it is almost impossible for a physician today to keep a thorough familiarity or even to be adequately conversant with all the tributaries of medical learning. This profuse light of knowledge has of necessity brought about grouping and specialization in the various branches of medicine, each physician seeking to collect the rays of new thought and to concentrate them in the field of this particular activity.

The public health is more efficiently guarded today than it ever was before, for not only has the span of life been increased according to statistics by at least ten years through hygienic vigilance, but life itself has been placed on a higher plane of sound health by the precise means of early diagnosis and treatment. Hospitals and clinics were perfected by the establishment of clinical and pathological laboratories, by the construction of x-Ray machines and electrocardiographs, by instituting aseptic surgery, by delving into the benefits of blood transfusion and intravenous medication, by the standardization of pharmaceuticals, and the enhancing preventive

medicine through the study of infection and immunity. The recent studies of *x*-Ray, Radium, Actino, Physio and Electro-therapeutics, hold out much hope in the beneficence of curative medicine. Of course, medicine has still much to learn and more to conquer, but surely the public cannot look forward towards a solution of any of the biologic, morphologic, physiologic or pathologic problems to any of the existing and much-thriving sects with their preposterous cults. The solution must emanate from the physician living within the confines of the cloistered laboratory, from the clinician observing the patient at the bedside, and from the pathologist who surveys the cellular transitions in the cosmos of the microscope. It is amazingly surprising to find that in the present light of universal progressiveness, some people are still willing to take the counsel of charlatans and fakers, that they are still consulting upon matters of health with chiropractors, Christian Scientists, neuropaths and naprapaths, a herd deplorably steeped in ignorance and utterly devoid of any knowledge appertaining to the disorders of the human economy. And even our legislators, the guardians of public welfare, either through misinformation or to gain political advantages, very often incline towards their favor. It seems that Barnum's statement referring to the prolificity of fools is destined to become a classic.

But in spite of many discouragements, the caldron of medical experimentations is constantly being filled with new problems and thoughts which keep on crystallizing for practical application. It seems to be the glorious ambition of every medical man to make some contribution to the treasury of medical knowledge, because the physician has always realized that of all the human possessions, health is the greatest asset. And since by virtue of his training this most valuable possession is placed into his hands, he has ever guarded this trust with the ardor of fealty and fidelity. Most physicians are prompted by a sincere desire to render the best service to humanity, and look upon disease as a public calamity in whose eradication the entire profession must participate. And to quote from my inaugural address: "The medical man lives for the medical cause, sacrificing not only the comfort that comes with material wealth—which the average physician can never hope to attain as he does not patent his discoveries—but he is often compelled to struggle for the bare necessities of a simple existence. And the public reaping the benefits of these sacrifices owes a great deal to the medical profession, more than it is likely ever to become aware of." (N. Y. STATE JOUR., Wed. Dec. 15, 1930, Page 1467).

But in order for the physician to continue in his devotion to service and make possible the rise of men like Brown Sequard, Pasteur, Lister, Jenner, Virchow, Claude Bernard, Koch, Ehrlich, Ewing and Banting, his freedom of thought, his initiative, his integrity and his self-determination must be fully and wholly retained. He cannot continue to exist and render valuable service unless he is assured of those conditions which will make it possible for him not merely to eke out an existence, but to meet with assurance and a degree of comfort, the economic and social demands of his responsible position.

Recently much talk has been given to the socialization of medicine. But society can ill afford to risk social experiments with the guardians of so valuable an asset as health. For under the most perfected conditions such a régime would not only hinder the physician in the performance of his duties according to his own dictates and best judgment, but would positively destroy the spirit of devoted interest so essential in the study and investigation of medical science. And no matter what system would be instituted for the control of medical care, whether State or corporative, the physician of necessity would become either a "political football" subject to political favor, or he would become the hireling of an insurance company with the glorious prospect of a "clock-puncher."

In order that medicine maintain its scientific integrity for growth and development, it must bask in the sunshine of freedom, it must live in the atmosphere of inspiration. Any other scheme would shackle the spirit of ideality, would stunt potentialities and force a noble profession to "stoop to conquer."

VARIOUS ANESTHETICS AND CERTAIN METHODS OF THEIR ADMINISTRATION: INDICATIONS AND CONTRAINDICATIONS FOR THEIR USE*

By JOHN S. LUNDY, M.D., ROCHESTER, MINN.

From the Section on Anesthesia, The Mayo Clinic, Rochester, Minnesota.

IT will be the object of this paper to present facts which in general should aid in selecting the anesthetic for a given case. The considerations involved in this process may be said to be preliminary and final. The final considerations are concerned essentially with the pharmacologic effect of the drugs as modified by the methods of administration. The preliminary considerations are concerned with the remainder of the factors relevant to choosing an anesthetic. In the choice of an anesthetic one begins, as a rule, with the preliminary considerations and then continues with those that are final. An example of the effect of the preliminary considerations on the choice of an anesthetic or a method might be that if the anesthetist, as well as other members of the surgical team, is unfamiliar with spinal anesthesia, it would be well to avoid this method. If the mental condition of the patient is such that he refuses a certain type of anesthesia then it may be well to avoid that agent and method. An example of the effect of the final considerations on the choice of the anesthetic might be that if it is necessary that the patient recover consciousness quickly, or that he speak during the operation, it would be well to avoid the administration of agents which would prevent such a result.

The introduction of various new drugs as anesthetic agents has increased the number of such agents and has, to some extent, complicated the problem of eliminating all but the anesthetic of choice for the individual case. I feel that the choice of an anesthetic is best made by following a definite plan or scheme. The preliminary characteristics to guide one are: (1) the mental and physical condition of the patient, (2) the proposed operation, (3) the technic of the surgeon and (4) the experience of the anesthetist. Each of these factors, if given proper consideration, tends to exclude certain agents and methods and so to limit one's choice. The final considerations in making the decision are: (1) is the need for anesthesia or for analgesia? (2) is relaxation necessary? (3) is quiet breathing necessary? (4) is quick recovery of the reflexes desirable or necessary? and (5) is this agent or method likely to produce immediate or delayed untoward results? Each agent produces certain effects which limit its use, and these effects must be borne in mind in the application of the agent. I shall speak briefly of several agents that are more or less widely used.

*Read before the Buffalo Academy of Medicine, Buffalo, New York, November 5, 1930.

Derivatives of Barbituric Acid

Beginning with the hypnotics, I shall speak of the barbiturates as they occupy considerable attention at the present time.

The consensus of opinion is that the barbiturates are definitely useful as hypnotics, sedatives and antispasmodics only. These agents have been employed for the purpose of producing anesthesia, but the results indicate that a dose larger than that which will produce hypnosis carries with it an increased danger which is directly proportionate to the dose. It is well to bear in mind that the effect of a barbiturate is not essentially related to the method of its administration but rather to the dose. It is of especial interest that the small hypnotic dose of sodium *iso*-amylethyl barbiturate (sodium anytal) is being used to advantage instead of morphine to hasten labor in primiparae by administration of the drug when the cervix is dilated 3 to 4 cm. Barbiturates in small doses produce some analgesia but little anesthesia. Relaxation is facilitated by their use but it is not produced directly by small doses. Breathing is more quiet if the barbiturates have been used than if they have not. Very small doses do not delay the recovery of reflexes particularly, but large doses do retard the return of reflexes. Small doses seldom produce immediate or delayed untoward results, whereas large doses not infrequently produce remote untoward results. I prefer to control the preoperative anxiety and fear of a patient by administering a small dose of a barbiturate at bedtime the night before the operation, repeating the dose an hour before operation, and following this with a hypodermic injection of a small dose of morphine and atropine. More uniformly good results may be obtained following the use of any anesthetic agent if the patient is brought to the operating room in a degree of sedation which relieves the patient to a large extent of apprehension. An excited, apprehensive patient requires more anesthetic than a confident, quiet patient, and those who prepare the patient for operation should bear in mind that the preoperative treatment of the patient should work toward the reduction of the risk from the anesthetic as well as toward the reduction of the risk from the operation by improving the patient's mental as well as physical condition. In the postoperative period, the use of oxygen and carbon dioxide

for hyperventilation is a good precautionary measure against postoperative pulmonary complications and should always be available for use.

Tribromethyl Alcohol (Avertin)

The alcohols represent the next class of agents. I shall speak of the one which is probably the most widely used at present, tribromethyl alcohol, tribromethanol, or avertin. This agent should be used generally as a basic anesthetic only. Its use should be avoided in the presence of advanced hepatic and renal disease, in pulmonary tuberculosis with cavitation, in marked bronchiectasis, and in colitis. If it is used in old people only small doses should be employed.

I find it advantageous to give more preliminary medication when using this agent as a surgical anesthetic, than when using almost any other. It has been my custom to administer chlorbutanol (chloretone) grains 10, by mouth or by rectum, a small dose of a barbiturate, and morphine grain 1-6, with atropine grain 1-150 by hypodermic injection prior to the rectal administration of 1.5 c.c. of 3 per cent solution of tribromethyl alcohol in 6 per cent solution of gum acacia for each pound of body weight, and in addition, local, regional, or gas anesthesia.

In obstetrics this agent may be used, but I believe that at the present time other agents are probably equally as efficient and more convenient to use.

The optimal dose of tribromethyl alcohol produces analgesia and sometimes anesthesia. Relaxation is facilitated and breathing is usually quiet, but recovery of the reflexes is delayed. The frequency with which untoward results appear is as yet uncertain, although it is rather definitely established that small doses usually are without untoward result if use of the drug is not contra-indicated by the patient's physical condition.

Anesthetics Given by Inhalation

It is wise to avoid the use of chloroform in almost all cases if possible because of its untoward effect on the heart and its delayed untoward effect on the liver in occasional cases. Deaths have been ascribed to its use. However this drug has been extensively used with gratifying results. Apparently the important factor in its use is slow administration of a well-diluted vapor. The dilution apparently depends on the amount of oxygen in the mixture. It has been said that chloroform is safer when administered with oxygen than with air. Anesthesia, relaxation and quiet breathing are usually associated with this drug, and the time for recovery of the reflexes is not particularly long. However, as has been said, immediate and remote untoward results have been reported.

Ethyl chloride is useful for inducing anesthesia that is to be carried on under ether, or for short periods of anesthesia required for minor sugical procedures. It should be given by the drop method, not sprayed on the mask. This agent is being given by the closed method by a few anesthetists and with considerable satisfaction when the dose administered is small and the vapor is not concentrated. Recently I have used this agent but little because of the sudden deaths reported incident to its use Anesthesia is quickly produced by ethyl chloride, relaxation is not usually obtained, breathing is not particularly quiet, the period of recovery is short, and immediate untoward results have been reported.

Ether, the most extensively used of all anesthetic agents in the past, is one of the most reliable available agents. The physiologic effect of this agent depends to some extent on its method of administration. The one most commonly used is the open-drop method. Usually results with this method are uniformly satisfactory if the vapor administered is not too concentrated and if preliminary medication is not sufficient to depress the respiratory center. The closed method of administering ether is facilitated by the admixture of anesthetic gases and of oxygen and carbon dioxide. It is best to establish anesthesia with low concentrations of ether, by means of deep breathing through the period of induction, and by using the gases not only as vehicles for ether but as synergists in obtaining anesthesia. It is essential in this method that the percentage of oxygen be sufficient adequately to maintain metabolism. Good results have been obtained from hyperventilation of the lungs with a mixture of carbon dioxide 5 per cent and of oxygen 95 per cent following anesthesia by inhalation of ether.

The intratracheal modification of the closed method is one of the most outstanding advances in methods of administration. This has been brought to a high point of perfection by Magill of London, who uses a fairly large soft rubber catheter. It usually may be passed through the nose and into the trachea after treatment of the larynx with a cocaine spray and following light general anesthesia. The patency of the airway is maintained, with the result that breathing is quiet, relaxation is facilitated, and administration of the agent or agents is made easy.

The colonic or rectal method of administering ether in oil has been used satisfactorily by many, but for safety one must carefully reg-

ulate the concentration of the ether in the olive oil. I feel that ether 65 per cent and olive oil 35 per cent is about the optimal mixture for surgical purposes. This method requires that the patient be given preliminary medication sufficient to insure that he will not quickly exhale the ether, thereby rapidly diluting its concentration in the blood stream and thus shortening the duration of anesthesia and lessening its depth. It would be well to use ether by this method as a basic anesthetic rather than in an attempt to produce complete anesthesia. Intravenous administration of ether and saline solution is worthy of mention, but as yet the method has not been widely applied and it will not be considered here in any further detail. Ether produces anesthesia, and relaxation may be produced with fairly large doses. Breathing is quiet with the intratracheal and rectal methods but is not particularly quiet when ether is given by inhalation. Recovery of reflexes is definitely delayed, and varies with the amount of ether administered. Although immediate untoward results are seldom seen, remote untoward results are said to occur not infrequently.

Nitrous oxide is widely used and is a valuable agent, particularly because it is not inflammable, is not particularly unpleasant to inhale, and is not irritating to the lungs. It is especially useful for short minor operations and for operations in which relaxation is not necessary. In administration of this agent more than in administration of most other agents, it is essential that preliminary medication be adequate. This agent is frequently resorted to when other general anesthetic agents seem to be contraindicated. Anesthesia and analgesia may be produced by nitrous oxide. Relaxation is usually not obtained and breathing is not quiet. The reflexes are quickly recovered. Immediate and remote untoward results should not occur.

Ethylene, when its inflammability does not contraindicate its use, is fully as valuable if not more valuable, than nitrous oxide. Twice as much oxygen may be administered with ethylene as with nitrous oxide and equivalent anesthesia and also considerable relaxation can be obtained. Breathing is not particularly quiet and reflexes are recovered easily. Immediate and remote untoward results should not occur except through the inflammability of the agent. With both nitrous oxide and ethylene it is often advantageous to administer small amounts of ether. With either nitrous oxide or ethylene, preliminary medication is important. In many surgical and obstetric cases nitrous oxide or ethylene may be preferred to other agents.

Local Anesthesia

Advances in local anesthesia run concurrently with the introduction of new agents. At the present time I feel that procaine when used in solutions not exceeding 1 or 2 per cent is the safest local anesthetic agent available, and so, of the many local anesthetic agents, I shall discuss only procaine.

Analgesia is produced by procaine. The amount of relaxation produced depends on the method used. Breathing is usually quiet except in excited patients or in patients who are suffering pain either from the operation or in other parts of the body than those being operated on. Reflexes return early. Immediate and remote untoward results should not occur.

When used by the infiltration method in a 0.25 or 0.5 per cent solution procaine is used with great safety if intravenous injection is avoided. The administration of small doses of a barbiturate because of its antispasmodic property may add to the safety of local anesthesia. Certain untoward results are incident to its use when it is combined with large amounts of epinephrine. I prefer to use epinephrine in very small amounts; about 6 minims of 1 to 1000 solution in 200 c.c. of 0.5 per cent solution of procaine. In the average case I prefer to use not more than 100 c.c. of 1 per cent, or 200 to 250 c.c. of 0.5 per cent solution of procaine. The method of infiltrating the line of incision is valuable and may be applied by the surgeon, his assistants or the anesthetist. Because of its relative safety, this method should be used when the safety of other methods is questioned. In some instances it seems advisable to avoid direct injection into the field of operation and then the most frequently used of the so-called regional methods of anesthesia may be employed, namely, field block, wherein the field of operation is surrounded with a wall of anesthetic solution, so that the site of operation is anesthetized without being infiltrated. Abdominal block anesthesia is an illustration of a type of field block. Two useful methods of regional anesthesia may also be mentioned, brachial plexus block, and sacral block. By these methods the anesthetic solution is injected at a point distant from the field of operation and yet blocks conduction through the nerves supplying the region of the operation. These methods of employing procaine are very valuable and are applied by many with the greatest satisfaction and with relative safety.

The decision whether or not to use spinal anesthesia, by means of injection of procaine, depends essentially on the degree of relaxation considered necessary for the operation. This procedure, according to my experience,

is best carried out by bearing in mind that (1) the rate of injection should be constant, 0.5 c.c. each second, (2) the point of injection should correspond to some extent to the site of operation, (3) routinely, the number of cubic centimeters of spinal fluid in which the dose of procaine is dissolved should be increased in proportion to the extent cephalad to which it is desired to produce anesthesia, and (4) the dose administered must be a safe one. In the average person the safe dose is about 1 to 1.25 mg. for each pound of body weight. It is essential that readings of blood pressure be taken before, during and after administration of a spinal anesthetic. I have obtained rather uniformly successful results by the administration of ephedrine immediately before the anesthetic is administered subdurally. However, in cases of hypertension it is best to administer the ephedrine after the procaine has been deposited. Gratifying results may be obtained by administration of oxgen or of oxygen and carbon dioxide during the operation if periods of nausea occur. When these agents are insufficient to control the nausea, then one may find that the administration of nitrous oxide or ethylene with the oxygen is effective.

Spinal anesthesia may be used with considerable satisfaction for operations on the viscera below the diaphragm if small doses of anesthetic solution are administered and if it is used only in patients in whom it is not contraindicated by recent debility, hypotension, marked cardiovascular disease, or diseases of the central nervous system.

Indications and Contraindications in Different Operations

A patient for operation on the brain is usually in fair physical condition in respect to respiratory and cardiovascular systems unless the lesion is very far advanced or is due to recent trauma. In operations on the cerebrum, ether by the open-drop method is usually satisfactory. It has been used with considerable, although probably less, success by rectal instillation with olive oil and with considerable safety by the intratracheal method. For operations on the cerebellum, or when the respiratory center is likely to be affected, the intratracheal method has definite advantages, as it facilitates ventilation of the lungs. The use of the barbiturates is not as a rule indicated in operations on the brain. Tribromethyl alcohol is being used with considerable satisfaction, especially when combined with local anesthesia. However, local anesthesia is usually resorted to when it is considered that other methods would add to the risk of the operation. The gases have probably been used with less satisfaction than most other agents for these operations. For operations on the face, the intratracheal method of administration of ether or of the gases, or of a combination of these agents, has been particularly satisfactory. These operations may be done, also, under rectal anesthesia with tribromethyl alcohol or olive oil and ether, but my preference is for the intratracheal method, especially if the operation is to be a plastic one, and if the space ordinarily occupied by the anesthetist encroaches on the operative field. Mastoidectomy can be carried out successfully under inhalation of nitrous oxide or ethylene. Simple operations on the eye are probably best done under local anesthesia. This may also be true of most operations on the nose and for tonsillectomy in adults. Tonsillectomy in children is probably best done under ether. Extraction of teeth is particularly satisfactory under block or conduction anesthesia, but if the patient is very nervous it may often be advantageous to use nitrous oxide by nasal inhalation.

Operations on the thyroid gland are usually carried out satisfactorily under infiltration anesthesia, using procaine solution without epinephrine, and after medication with morphine and a barbiturate. These operations also are done with considerable satisfaction by using gas anesthesia, especially at the time that the gland is being delivered. Operations on the submental and submaxillary glands of the neck, or for sinus of the thyroglossal duct, may be done with good results under cervical block anesthesia if sufficient preliminary medication has been administered. Recently, with tribromethyl alcohol and local anesthesia, excellent results have been obtained, and probably the patient has had less pain than under local anesthesia only. In laryngectomy I believe that the best results are obtained by the use of cervical block anesthesia. In operations on the cervical portion of the spinal cord, cervical block anesthesia with or without tribromethyl alcohol, or with or without light anesthesia with ether given by the open-drop method has been very satisfactory.

For operations on the upper extremities, rather wide choice exists. Operation may be done under any method of administration of ether or a gas, or under local or regional anesthesia. Many times the results obtained from brachial plexus block anesthesia are excellent. In such operations, the method of anesthesia chosen for use may be that in which the anesthetist is most skilled.

Minor operations on the thorax may be carried out under local anesthesia or under anesthesia by a gas with almost complete satisfaction. Radical amputation of the breast is

facilitated by quiet respiration. The intratracheal method of administering a gas or ether is particularly satisfactory for this operation. However, most patients do well under ether administered by the open-drop method. For operation within the thorax, such as thoracoplasty, ethylene and nitrous oxide anesthesia, with a moderate amount of preliminary medication, has been satisfactory in my experience, although many advocate the routine use of local anesthesia and that may be the method of choice except if the operation is done in several stages. For operations on the lung or within the thorax, in which the pleura is opened, the intratracheal method of administering a gas, with or without ether, and following some preliminary medication, is usually essential. Operations for diaphragmatic hernia also are carried out advantageously under the intratracheal method of anesthesia, using gas and ether.

For operations in the upper part of the abdomen, in which relaxation is necessary, spinal anesthesia is particularly valuable, especially if it is probable that postoperative pulmonary complications may ensue. It is frequently advantageous to combine spinal anesthesia with a gas. However, if relaxation is not necessary, the operation may be done under infiltration or field block of the abdominal wall with or without anesthesia by a gas. The safest method of anesthesia in cases of serious risk is probably infiltration, or field block; the next safest method is probably inhalation of ethylene. In some cases of hypotension, in which the relaxation must be secured, ether given by the open-drop or intratracheal method probably is the method of choice.

Operations in the lower part of the abdomen may be done under spinal anesthesia, unless it is contraindicated. About the same methods are indicated in operations in this region as in operations in the upper part of the abdomen, if conditions of operative risk are similar. However, in operations on or through the urinary bladder the procedure may be carried out under sacral and abdominal block with considerable safety and satisfaction; in such circumstances, the safety of other methods may be open to question. Herniotomy may be performed under many types of anesthesia but local anesthesia usually is preferable.

Operations on the perineum may be done under anesthesia with a gas, and the female patient usually prefers to be unconscious during such operations. However, sacral block or spinal anesthesia may also be used with considerable satisfaction. This is particularly true in operations on the anus and rectum and especially true for such operations as hemorrhoidectomy. For this operation, sacral block anesthesia may be used to advantage almost routinely. For hemorrhoidectomy, I feel that spinal anesthesia provides more extensive anesthesia than is necessary and that infiltration anesthesia distorts the tissues too much and does not produce sufficient relaxation. Sacral block anesthetizes practically only the field of operation and provides ample relaxation without distortion of the tissues. Circumcision and other operations on the penis in the adult patient are probably best carried out by field block in which injections are made at the base of the organ. Manipulations and operations through the cystoscope may be done with considerable satisfaction under gas anesthesia or with sacral block anesthesia. In some instances, as in tuberculous bladder and cord bladder, spinal anesthesia is indicated.

Operations on the lower extremities may be carried out under almost any form of anesthesia. Certain operations such as those for bunion should be done under field block anesthesia. Amputation of the leg is very satisfactorily performed under spinal anesthesia.

For obstetric procedures anesthesia with a gas has been very satisfactory. A recent advance in this field has been the oral administration of small doses of sodium *iso*-amylethyl barbiturate as soon as the cervix has dilated to the width of 3 or 4 cm. This is followed by inhalation of a gas in the third stage of labor. Chloroform has been used extensively in obstetrics but reports of delayed central necrosis of the liver have discouraged its employment. Ether administered by the open-drop method has been the most widely applied agent and has given excellent results. The barbiturates in large doses, and tribromethyl alcohol have been used, but certain disadvantages are said to follow their use. Ethyl chloride has no place in obstetric anesthesia. Spinal anesthesia is probably not indicated in normal labor but it may be used at times to advantage in operative obstetrics. Sacral block anesthesia has been used to advantage in operative cases but not in normal labor. In cesarian section anesthesia with a gas, or with ether administered by the open-drop method, spinal anesthesia induced by low injection or even infiltration anesthesia has been uniformly successful in the hands of many.

The Physical Condition of the Patient

In the presence of diabetes, ether is probably contraindicated. In pulmonary disease anesthetics given by inhalation other than the gases probably are contraindicated. In extensive cardiovascular disease, spinal anesthesia probably is contraindicated. Epinephrine

raindicated in extreme hypertension and presence of hyperthyroidism.

considering the technic employed by ns, those factors which facilitate a par- surgeon's obtaining his optimal re- must be considered. For example, re- n may be extremely important to one n and of less importance to another. rgeon may wish to have his patient un- ous, and another may be equally anxious that the patient be awake. Some surgeons work very rapidly, whereas others do not. For example, an operation for the cure of gastro-jejunal ulcer is done by some surgeons in the short period of anesthesia produced by procaine given intraspinally, whereas that operation by another surgeon may overrun that period of time. The surgeon who works more slowly may prefer general anesthesia alone or in combination with spinal anesthesia.

USE OF ATROPIN OR ITS DERIVATIVES FOR TREATMENT OF DISEASE

By THEODORE S. EVANS, M.D., NEW HAVEN, CONN.

Read before the Grace Hospital Staff, New Haven, Conn.

HE literature for the past seven years, in- luding 1930, is full of references to the use f atropin or its derivatives for treatment of e. In none of the literature examined, includes practically every reference that be obtained, was there a report of a toxic f such small size as the one herein reported. is work on the diagnostic value of atropin s of early typhoid fever, N. Fairley Marris[1] ed 256 cases of typhoid fever and 353 which not typhoid fever, a total of over 600 cases ich he used 1/33rd of a grain of atropin per without inducing any toxic effect. This is thirty times the dose which caused the toxic in this case herein reported.

k J. White,[2] of St. Louis, reported reactions included fever and increased pulse rate, but pillary changes and no erythematous blush 1/000th grain in three-day old children. He es this was due to direct stimulation of centers similar to the fever seen in certain of cerebral hemorrhage. His viewpoint in regard is supported by Solis-Cohen and ns[8] and Cushny.[6]

well[7] and Sollman,[9] however, both feel that ever is due to the suppression of the function e sweat glands.

nzing[4] makes the observation that infants tol- atropin proportionately better than adults, e does not give the reason for his conclusion.

orge Heller[10] reports a case in a five-day-old of 9/100th of a grain, used by mistake, h caused a mild reaction, dilatation of the s, fever, and erythematous blush.

orge Munns[11] reported a case in which six- doses of 1/1000th of a grain in a two-day resulted in skin rash, and abdominal disten- He also reported a case in a five-day-old where three doses of 1/1000th of a grain d fever, and abdominal distension without ation of the pupils. He reported a third case hich 1/500th of a grain for four doses in a nine-day-old child caused abdominal distension and fever. He also reported a fourth case of 1/60th of a grain in a seven-day-old baby which caused fever, and distension of the abdomen. In his fifth case, 1/500th of a grain in a three-weeks-old baby was used and caused distension of the abdomen, temperature, without eye signs or erythematous blush.

S. V. Haas[12] uses as routine 1/50th to 1/16th of a grain of atropin in every 24 hours for babies over 1 month of age.

In none of the accounts examined is there reported, even in children, a case of atropin poisoning from such a small dose as the one reported here.

Case Report

W. H. Seen Nov. 16, 1930, 28 years old, Male. Teacher of Salesmanship.

For the past two weeks, the patient has been suffering off and on with dyspnoea. This began two weeks ago, November 2nd. There was no reason which the patient could ascribe for the dyspnoea. His mode of life had not changed recently nor had any of his other habits. He consulted a physician, November 3rd, who told him that his intestinal tract was full of gas and that this was causing shortness of breath and palpitations of the heart. He also told him at this time that he had high blood pressure and a large heart. He left the physician's office and seemed to be all right the next day. Two days later, November 5th, he developed the same symptoms again.

His appetite has been good, no vomiting, nor nausea. There has been some belching of gas. The bowels are normal. There has been no edema nor cough. His voice has not been hoarse. The urinary tract is negative. Weight has remained normal. There has been no fatigue. He has been taking plenty of exercise. He smokes moderately and has not been drinking at all. He has no

dizziness, nor headache. Ears are normal. Throat has been "dry." During the past two weeks, the eyes have occasionally shown a slight blur when reading.

Past History: Scarlet fever, frequent sore throats, Vincent's infection, Surgical: Removal of appendix, tonsils and adenoids.

Family History: Wife is well. One child, 4 years old, in good health.

Medical Treatment: On November 2nd, at bedtime, the patient took "Alophen" tablets. This is the first time he had used a cathartic. On the 3rd, he consulted a physician for shortness of breath, dry throat, palpitations of heart and was told that he had gas in the intestinal tract, hypertension, and a large heart. The following day, November 4th, he was free from symptoms. On November 5th, he again took one "Alophen" tablet. The distress was marked. He went to a hospital where he remained for four days. While he was there, he was fluoroscoped, he had a gastro-intestinal series, he had an electrocardiogram made, and examinations were made of the blood content, urine, feces, and stomach contents: all of which were normal. He left the hospital, November 12th, and was free from the symptoms until November 16th at which time he gave the above history of shortness of breath, etc. From the time of his discharge from the hospital until 12 noon on November 16th, he had taken no medication of any kind, but noticing that he had a slight "nose cold," he took one "Rhinitis" tablet at 12 noon, on the 16th. He is certain that he took only one and that he had used no medication of any kind for the antecedent four days.

Physical Examination: He presents a well nourished and developed man. Temperature 100, pulse 120, blood pressure 120-80, on three different readings. Eyes: the pupils are dilated. The eye grounds are easily examined because of the dilatation of the pupils. They are normal. The teeth are normal. The throat is bright red. It is very dry. The tonsils are buried, and not visibly infected. The neck nodes are slightly enlarged. The heart is normal in size and rhythm; it is fast; no murmurs are heard. Lungs are clear throughout. The abdomen shows scar of appendectomy. He has a hydrocele on the left side. The extremities are normal. The reflexes are normal. Rectal examination is normal. The skin shows a slight erythematous blush.

After getting the history and making the physical examination he was told that he had atropin poisoning from the "Rhinitis" tablet. He then volunteered the following information:

That one drop of atropin had been put in his eyes when he was having them examined one time previously, and that it was a matter of ten days after that before the vision became entirely distinct.

November 17th, although the pupils are still dilated, the heart rate is only 80. The skin is clear, the throat is no longer dry nor red. November 18th, the pupils react to light and accommodation.

As there is absolutely no reason to doubt the patient's history, I should say that this is a case of atropin poisoning. The toxic dose in this case is extremely small. The "Rhinitis" tablet used was one of the "half strength" variety. The total dose of Belladonna was 1/8 grain, or atropin 1/800th grain. The "Alophen" tablet contained Belladonna 1/3 grain, or atropin 1/300th grain.

Summary

This case is reported for two reasons:

(1). Atrophin is a drug in very common use in such preparations as Rhinitis for colds, and various cathartics.

(2) There is a very wide individual idiosyncrasy of the drug as is proven by this case of poisoning resulting from 1/800th grain dosage.

FLY LARVAE AND OSTEOMYELITIS

The first article in this Journal is an important contribution to the literature on the treatment of chronic osteomyelitis That disease is often notoriously hard to cure, even when dead bone and tissue and all other apparent causes of non-healing have been removed The St Charles Hospital in Port Jefferson is a hospital home to which a great number of crippled children from Brooklyn are sent, among them being old cases of osteomyelitis which have resisted treatment for months. The series of such cases reported by Doctor Child will be of great interest to all physicians of New York State.

THE GRIEVANCE COMMITTEE

The Grievance Committee that was appointed according to the provision of the Medical Practice Act passed in the Spring of 1926 (Public Health Law, sections 1264-5, held its organization meeting on September 2nd of that year, as stated in this Journal of September 15, 1926, page 802. Major articles describing the work of this Committee have appeared in this Journal from time to time as follows:

"The first year of the Medical Practice Act," Rypins, Journal of December 15, 1927, page 1359.

Editorial, July 1, 1928, page 787.

"The Grievance Committee in the Medical Practice Act," Wightman, Journal April 1, 1929, page 391.

"The Work of the Grievance Committee," Rypins, Journal September 1, 1929, page 1073.

"The Standards of the Grievance Committee in the Acceptance of Rebates," Journal May 1, 1930, page 547.

The Grievance Committee, being an entirely new body, had to adapt its methods to conditions as they arose; but in the course of two or three years, its experience enabled it to develop methods which have proved eminently satisfactory and successful. Physicians throughout the State are not yet fully aware of the scope of the activities of the Grievance Committee and of the methods of its action, for the Committee conducts its work quietly and with due regard to the feelings and reputation of the physicians who are investigated. Physicians will therefore be interested in the report of its work which appears on page 952 of this Journal.

The primary object of the law establishing the Grievance Committee was to provide a committee of medical men who should hear charges of unprofessional conduct brought against physicians, and should report their findings to the Department of Education, under whose jurisdiction and authority the Committee acts. The licensing of practitioners of medicine, the revocation of their licenses, and the investigation of complaints that may involve revocations are functions of the State Department of Education; but the investigation and prosecution of practitioners for illegal professional acts is a function of the Attorney General also. Specifically the Grievance Committee is a part of the machinery of the State Department of Education. It is a sub-committee of the Regents of the University of the State of New York, and reports its findings to the Regents.

There are therefore three official bodies that are charged with disciplining physicians for conduct that is either unprofessional or criminal:

1. The State Department of Education—the Regents, who issue licenses to practitioners.

2. The Attorney General who is concerned with the criminal acts done in the professional practice of physicians.

3. The Grievance Committee who is concerned with professional standards applying to physicians under charges.

The description of the regular course of events following charges against a licensed practitioner of medicine will help a doctor to understand the procedure of the Grievance Committee.

Charges may be brought by any person against a physician. They are to be made in writing and signed by the complainant and sent to the Secretary of the Grievance Committee, Dr. Harold Rypins, Educational Building, Albany, N. Y. Doctor Rypins is also Secretary of the Board of Medical Examiners, and is therefore familiar with the methods of granting licenses as well as their revocation.

The Secretary gives due consideration to the complaint and makes a preliminary investigation sufficient to disclose the importance of the complaint; and if he finds it to have a legal basis, he refers it to the Attorney General for an opinion. If the Attorney General decides that the charges warrant further consideration, they may be referred to the Grievance Committee. There has never been friction between these two official bodies, for the Attorney General is concerned with the criminal phases of the complaint and with the securing of legal evidence; while the Grievance Committee is concerned with the interpretation of the medical practice act. Each body therefore supplements the other, but the Grievance Committee fills a need that has never before been supplied.

The Grievance Committee is a legal tribunal which may compel the attendance of witnesses; but it may also hold informal hearings which often lead to amicable settlements when formal hearings in public would only irritate the parties. Informal hearings also enable the Committee to decide when an action of a formal nature should be brought, for the attitude of the accused is a vital factor in every case. The Committee therefore represents not only the medical profession but also the people of the State.

The law also makes provision that in cases of dispute between individual doctors, the Committee may act as a court of arbitration when requested by both parties; and in this case the decision is final, and no appeal from it may be taken.

Physicians should understand that merely calling the attention of the Grievance Committee to an alleged irregularity is not sufficient to set its machinery in motion. The Grievance Committee acts only on complaints referred to it by the Regents; and the Regents usually obtain an

opinion from the Attorney General's office as well as from the Grievance Committee.

Many complaints sent to the Grievance Committee properly belong to the County Medical Society. Physicians sometimes charge their medical brethren with unwise acts in which no law is violated, and which therefore do not come within the jurisdiction of the Grievance Committee, or the Attorney General, or the Department of Education. Examples of such complaints are:

Inserting advertising cards or announcements in the newspapers.

Accepting salaried positions with corporations.

Continuing to treat patients referred for consultation only.

Such actions as these come within the jurisdiction of the county medical society. The physicians practicing in the county are familiar with local customs and the temperaments of all persons concerned with the complaint, and can make decisions more wisely than those connected with any outside organization. It is much better that a county society should exercise its own liberal prerogatives and opportunities in disciplinary matters, rather than pass them on to a higher tribunal, which is governed by the strict provisions of the statute law.

The Grievance Committee has been a success in giving medical points of view to the representatives of the Department of Education and the Attorney General in the application of the legal principles of disciplinary actions against physicians.

PLANNING HEALTH LEGISLATION

Past experience in public health legislation has demonstrated the essential value of giving publicity to the studies and debates of the promoters of the new laws. The public health bills which were introduced in the Legislature late last year had been proposed by a special group of persons appointed by the Governor; but certain features were opposed by a large group of local health officers composing the Sanitary Officers Association, and other features were questioned by the members of the Medical Society of the State of New York. Both of these organizations are taking steps to study all phases of the report of the Governor's Commission, and to inform the medical profession regarding public health conditions as they are and as they should be. (See page 973.)

LOOKING BACKWARD

THIS JOURNAL TWENTY-FIVE YEARS AGO.

Medical Legislation:—This Journal for August, 1906, contains the following remarks by Dr. A. G. Root, of Albany, Chairman of the Committee on Legislation, concerning three bills, all of which were passed by the Legislature within a few years.

"The year had been one of the most trying in the eleven years that he had served upon the Legislative Committee; the crop of special bills legislating into the profession men entirely unfitted for its duties, special bills for the licensing of men in special subjects which were purely medical, and bills to endeavor to destroy the present enactments, had been large. Two of these bills narrowly failed of passage. It was thought that last year's fight against the osteopaths was a serious one, when the bill failed of passage in the Senate by only one vote. This year the bill actually passed the Senate and in the Assembly was referred to the Committee on Public Health, where, fortunately and with much labor, it was kept until the end of the term. The Optometry Bill was only at one time in danger of passing and this danger was caused by the inactivity of the profession throughout the State. In fact, the greatest danger is the passiveness of the profession in matters which directly interest it. If from all parts of the State physicians manifest their opposition to any measure, that opposition will be completely effective.

"One bill was reported from the Committee on Public Health which would solve the entire difficulty. This bill gives the most explicit, concise and exclusive definition of the practice of medicine, and, at the same time, provides for one State Board of Examiners to be appointed by the Regents, which shall be composed of nine members; and before this State Board shall come all applicants for medical licensure, whether regular, homeopathic or eclectic. This bill also failed of passage because of the inactivity of professional support and at the same time because of opposition on the part of homeopaths and eclectics."

MEDICAL PROGRESS

Inhalation Treatment of Angina Pectoris and Intermittent Claudication.—In a long series of experiments, from fifteen to twenty-five years ago, Yandell Henderson and his collaborators demonstrated on dogs, under artificial respiration or breathing naturally under a slight pressure of air after opening the thorax, a condition verging on tetanus of the heart, which was effectively counteracted by a restoration to normal of the carbon dioxide content of the blood. Following these observations, it was shown that carbon dioxide may exert an equally strong influence upon the peripheral circulation, and particularly upon the volume of the venous return to the right heart. Clinically, the results are similar to the effects induced by amyl nitrite, but like those of a hot bath are more physiological than pharmacological. It is possible that the greater part of the benefit sometimes derived from the Nauheim treatment is due to the inhalation of carbon dioxide volatilizing from the surface of the bath. With these considerations in mind, carbon dioxide inhalation has been tried in three cases of angina pectoris in its earlier stages. The inhalations are not given during an attack of pain, but every day, usually before the midday and evening meals and at bedtime. The patient holds his own face mask which has a sufficiently large opening to the outside air to offer no resistance to breathing. He is told to breathe deeply rather than rapidly. A stream of carbon dioxide gas is fed through a small rubber tube from a cylinder of the pure liquefied substance. The flow of gas is at first kept small, but is gradually increased until a maximal or nearly maximal depth of breathing is developed. This condition is maintained for fifteen or twenty minutes. The essentials are an open mask, and a device for the control of the flow of gas to the mask, so that by no possibility can the patient receive an excess. Henderson describes in detail the apparatus which he employs. The results of the inhalation are a distinct improvement in the color and temperature of the lips and skin, a markedly fuller circulation is evident, the sensation of oppression in the chest and the pain or "pins and needles" sensation in the shoulder and arm is considerably decreased. After some weeks of daily inhalations the capacity to take exercise is markedly increased. In two patients with intermittent claudication of the lower extremities the inhalations continued for some weeks resulted in a distinct cumulative beneficial effect. Though the number of cases is small, the author nevertheless feels justified in recording them because of the striking results obtained and the convincing theoretical considerations upon which the treatment is based.—*American Heart Journal*, April, 1931, vi, 4.

Mediterranean Exanthematous Fever.—L. Cannavo describes in the *Riforma medica* of April 6, 1931, a case of a little-known affection which has appeared sporadically in Mediterranean countries during the last 20 years, instances of which, although reported under different names by different observers, must be ascribed to a single disease entity in view of their numerous common characteristics. This disease, best known as Mediterranean exanthematous fever, has a typical course and symptomatology. It begins abruptly, in the midst of florid health, with a violent chill followed by fever often reaching 40° C. (104° F.), which assumes a continuous course with, however, moderate remissions in the morning. Pain in the joints and muscles promptly appears, sometimes accompanied by tonsillitis, diarrhea, and vomiting. On the third to fifth day an exanthem appears, beginning on the thighs and lower part of the abdomen; after which in several successive crops it invades almost the entire surface of the body, including the palms of the hands and the soles of the feet. The eruption consists of spots intermediate between macules and papules, slightly elevated above the surface of the skin, becoming white on pressure, not confluent, without hemorrhagic phenomena, and each surrounded by zones of perfectly normal skin, thus being clearly differentiated from typhus exanthematicus. The appearance of these spots is so characteristic that the French in Tunis have suggested the name of "button fever." There is sometimes observed in addition, especially on the face, a small brownish spot the size of a pinhead to a small pea which it is believed represents the portal of entry of the specific virus. The patient's condition remains practically constant for 10-15 days, after which the fever drops by rapid lysis; the pains gradually diminish, the eruption fades and disappears without desquamation. Convalescence is brief, and full health is soon restored. Oftentimes, the nervous system is affected and the patient suffers with headaches, restlessness and not infrequently febrile delirium. Other organs of the body are little affected; occasionally there is moderate tumefaction of the spleen. Prognosis is favorable and there has been complete recovery in every case thus far reported. The possibility of this affection should be borne in mind in the differential diagnosis from other acute febrile adult diseases with an exanthem.

Head Murmurs.—Louis P. Hamburger states that his chief object in writing this paper is to revive interest in cephalic auscultation—a well nigh lost art. These murmurs may originate from intracranial, extracranial, or infracranial sources. In the intracranial group are the sys-

tolic "brain murmurs" of children. In the routine auscultation of the heads of seven babies under one year of age, Hamburger demonstrated a distinct systolic murmur in three, all of whom were anemic and one rachitic. Anemia is probably a contributing factor, though it is not a necessary accompaniment of these murmurs. If cephalic auscultation were more frequently practiced in the case of highly anemic patients these head murmurs analogous to accidental cardiac and venous bruits would often be discovered. A second group of head murmurs comprises those accompanying communications between cephalic arteries and veins, which may be intracranial or extracranial. They are acquired in a large proportion of cases by trauma, although they may be congenital or are classified as spontaneous. The simplest form of the acquired intracranial variety is that of a communication between the internal carotid and the cavernous sinus. It may or may not be attended by pulsating exophthalmos. In one of Hamburger's cases such a murmur persisted for nineteen years without the development of pulsating ophthalmos. Another variety of intracranial head murmur is that accompanying aneurysmal angioma. It is described as continuous with systolic intensification. Head murmurs may also accompany meningiomas and gliomas. A case is described in which a murmur resulted from angulation of the vertebral arteries, caused by foraminal herniation of the cerebellum due to the presence of a cerebral cyst. The rare murmur of an actual aneurysm of a cerebral artery was illustrated by one case. Another group of cephalic murmurs includes subjective and objective sounds which are transmitted headward in the direction of the blood current from their origin in atheromatous and possibly dilated carotid arteries. With this type other evidences of marked arteriosclerosis are present. The murmur of a cardiac valvular lesion or from the struma of Basedow's disease may also be conducted to the head. Head murmurs may arise in presumably healthy individuals without apparently adequate causes and may disappear without untoward results, as exemplified by two cases, which are described in detail.—*American Journal of the Medical Sciences,* June, 1931, clxxxi, 6.

A Case of Pulmonary Gangrene Cured by Collapsotherapy.—Writing in the *Schweizerische medizinische Wochenschrift* of April 11, 1931, Henri Curchod gives an account of a case he observed in a man of 47 who had for years exhibited symptoms of cavitary bronchitis, localized in the right lung and constantly aggravated by his occupation as a renovator of mattresses. His condition becoming worse to such a degree that he lost 12 kg. in weight in a month, he entered a hospital. On admission the roentgenogram revealed an infiltration of the entire right upper lobe, with a cavity the size of a walnut in its middle portion. The pulmonary flora consisted of streptococci, spirochetes, and fusiform bacilli, with no tubercle bacilli present. The fetid nature of the expectoration, the type of flora, and the patient's grave general condition led to a diagnosis of pulmonary gangrene. In view of the evidence of cavitation, phrenicectomy was performed under local anesthesia, followed over a period of two months by administration of tincture of garlic in large doses and intravenous injections of salvarsan. But as the fetid secretion continued undiminished and the cavity was still present, it was decided to have recourse to artificial pneumothorax, one month after the phrenicectomy. Small weekly insufflations of 250 c.c. each were given, which were gradually increased to 400 and even 600 c.c. Intratracheal injection of lipiodol 25 c.c. by the intercricothyroid route revealed the continuing presence of geodes in the median portion of the right apex. There was a febrile reaction of 39° C. (102.2° F.) without any grave sequels, after which the expectoration appeared to be improved. The pneumothorax was still pushed, in combination with strong doses of lugol designed for absorption (15-20 c.c. of a 1 per cent solution). By the end of 3 months the patient had made an excellent recovery and was practically free from symptoms. He returns to hospital every 2 weeks for renewal of his pneumothorax, which has strongly collapsed the right lung, especially the upper lobe. While it is not contended that collapsotherapy is indicated in every case of pulmonary gangrene, it is evident that in the case described no treatment could have been more efficacious.

Linitis Plastica.—In reviewing the literature Fred C. Coe finds that linitis plastica has been considered under many and various names and has been assigned to as many and as varied etiological factors. Some writers have thought it was due to syphilis and others that it was a form of fibrocarcinoma. Ewing, with whom the author is in accord, concludes that it is a peculiar form of gastric carcinoma, probably occurring in resistant subjects and originating from cells of limited growth capacity, which pursues a chronic course and tends to spontaneous regression of the tumor process. Fibrous and mucous degeneration overtakes most of the cell colonies and in many areas the carcinomatous elements are replaced by fibrosis. In its symptoms linitis plastica does not differ from gastric carcinoma. The course of the disease is variable, the shortest time recorded being five weeks and the longest fifteen years. The disease is more common in men than in women. The age is from 30 to 60 years, the usual age periods for other forms of gastric carcinoma. The outstanding *x*-ray finding is the exceedingly rapid emptying of the barium meal. The outline of the stomach is that of a narrow inverted cone. The cardiac portion is usually not involved. The cardiac portion of the esophagus can be seen as a finger-like projection. Peristalsis in the involved area is wholly lacking and the walls are

inelastic. Linitis gastrica may easily be confused with gastric syphilis. The differentiation can only be made serologically or on section. In syphilis the stomach is not shortened as in cancer, and the motlity is normal. Coe reports three cases of linitis plastica which were definitely carcinomatous, and in two of which there were metastases to other viscera. The third patient refused to be examined by an opaque meal. When a lesion suspicious of linitis plastica is seen in the stomach, the small intestine and colon, as well as the omentum and mesentery, should be carefully scrutinized for metastases. This point has not been sufficiently emphasized in the literature.—*Southern Medical Journal,* June, 1931, xxiv, 6.

A New Treatment for Carbuncles.—The aim of a rational treatment of carbuncles, says W. Gerlach in the *Münchener medizinische Wochenschrift* of May 8, 1931, must be to increase the natural defenses of the organism, for which reason operative intervention is unphysiological. With a view, therefore, to producing hyperemia, he has for four years been using injections of a sterile solution of substances obtained from *Arnica montana.* The action of this medicament constitutes a form of irritation therapy directed specifically to the vascular system. It has nothing to do with an "internal disinfection" or with any general stimulation of the organism. The injection is made subcutaneously in the vicinity of the carbuncle, at a point at least a handbreadth away from the focus, not into it nor distributed around it. Very small amounts are sufficient to produce a reaction. The injection is not repeated until the reaction has occurred, which is usually in 24 hours, but may not be for 48 hours. When the carbuncle is already near to softening. 1 or 2 injections are enough. Where there is still a strong tendency to spread, 6 or 8 injections may be necessary, but even in such cases the toxic action is arrested after 1 or 2 injections. Immediately after the injection a brief smarting pain is experienced, which can be relieved by pressure of the finger. The sense of tension and pain in the carbuncle is promptly diminished. In a few hours the pain returns, the temperature rises, and in 24 hours the bluish color of the carbuncle is changed to bright red, extending 1 or 2 fingerbreadths into the surrounding tissue. What has happened is that the already infiltrated zone has become hyperemic and the inflammation has reached a more acute stage. Signs of segregation of the inflamed zone from the healthy tissue soon appear, usually after 2 or 3 injections. A characteristic feature is the appearance of small pustular points in the carbuncle. Injections are stopped when the abscess has come completely to the surface. If there is a tendency to bleed, simple compression will usually control it. Gerlach has used this treatment successfully in over 50 cases. Local applications of wet arnica compresses are often comforting as an adjuvant. The cosmetic results are of the very best, and the treatment has the further advantage that it can be carried out by the general practitioner at the patient's home.

Disastrous Secondary Effect After Therapeutic Use of Benzoyl Peroxide.—David J. Macht states that he has had occasion to observe an interesting case of accidental injury after use of benzoyl peroxide, which has recently been recommended by P. D. Lamson for its remarkable results in cases of poisoning from *Rhus toxicodendron.* When employed in powder form directly upon the skin lesions, it produces slight local pain and destroys the toxicodendrol by its oxidizing properties. The case here noted came under Macht's notice by virtue of his being director of a pharmacological research laboratory of a concern which manufactures benzoyl peroxide. A man who was a victim of ivy poisoning in both arms and hands had received from his physician a prescription for benzoyl peroxide, with instruction to sprinkle it on the left arm and hand and upon two fingers of the right hand, and then apply bandages. After the patient had carried out these instructions, he lit a cigarette while he was in the course of a meal, and held it between the fingers of the right hand. The bandage took fire, the benzoyl peroxide exploded and destroyed the skin and a part of the muscles of the right hand. The injuries healed in the course of a short time, but the case is of interest in view of the fact that the danger of explosion in connection with the use of benzoyl peroxide is unknown to the laity and also to a good many physicians.—*Deutsche medizinische Wochenschrift,* April 17, 1931.

Vegetables as a Source of Vitamins. — A. Scheunert draws attention to the widespread misunderstanding that prevails with regard to the effect of cooking, sterilization, and preserving upon the vitamin content of vegetables. On the basis of experiments in young rats, he asserts that vitamins A and B suffer no loss through exposure to the heating process. Fat-soluble A especially is so abundant in those vegetables that contain it and is so little affected by cooking under all conditions that it is quite unnecessary to plead for its increased use in the raw state. Water-soluble vitamin B, while insensitive to heat, may be lost to an appreciable degree by prolonged washing of the vegetables after they have been cut up, or by failure to utilize the water in which they have been boiled. Vitamin C, on the other hand, is extremely sensitive to heat and loses a considerable part of its value under ordinary conditions of household cooking, in which the vegetables are freely exposed to oxygen. But when the vitamin is subjected to long cooking by steam under air-tight conditions, such as are provided in the mass production of canning factories, it loses little of its value. Hence the question of raw or cooked food regimens has not the importance that has been claimed for it in some direc-

tions. It is of interest, however, to note that even in raw vegetables variations of vitamin content occur, according to the age of the product, the soil in which it grows, and the time of its harvesting. Thus the oxidation of vitamin C takes place in the raw state also, if the vegetables are eaten otherwise than when freshly gathered. Especially do potatoes tend to lose their rich content in vitamin C when they are kept in storage or allowed to sprout. The effect of the fertilizer employed is also of a certain importance. The only vegetable known to contain vitamin D in considerable quantity is the field mushroom, grown in the open. This vitamin was found to be still present and unaffected when the mushrooms had been canned. In general it can be said that the content in vegetables of vitamins of all kinds is by no means constant, but varies with the type of soil, the time when they are picked or dug, and the conditions under which they are kept afterwards. —*Deutsche medizinische Wochenschrift,* May 15, 1931.

Treatment of Modern Scurvy. — On the basis of his own personal observations in arctic and antarctic regions, J. B. Charcot gives an account of a type of scorbutic disease which differs somewhat from classic scurvy and to which he inclines to give the name canned meat disease, or modern scurvy. All the cases he has observed have this important common factor in the etiology, viz., that irrespective of whether the patients had or had not consumed other food containing the necessary vitamins, they had all consumed over a considerable period of time preserved meat taken from cans. The first indication of the disease consists in a slight pretibial edema; the swelling progresses, invades the legs, then the thighs, scrotum and finally the abdomen, at the same time that small red dots appear upon various parts of the body, resembling flea-bites. Sometimes extensive ecchymoses make their appearance, especially at the larger joints, and there may be deep ulcerations on the joints of the fingers. Ulceration of the gums, on the other hand, is very rare. The patient does not suffer any severe pain, but experiences extreme fatigue and exhibits symptoms of myocarditis, the pulse being subject to variations from a rate of 30 to 160 beats per minute in the same 24-hour period. Administration of antiscorbutic food does not do the least good so long as the patient continues to eat canned meat. Herein lies the difference of the disease from ordinary scurvy. Charcot first observed this modern type of scurvy in a fellow-explorer on his first antarctic trip in 1903, and cured the man by withdrawing all canned meat and putting him on a diet of humanized milk. On his second antarctic expedition in 1908-1910 he himself and another comrade both fell victims to the disease, which assumed an exaggerated form. In his own case, abstinence from canned food for 4 days was followed by disappearance of all symptoms; in 5 days his comrade was likewise cured, not even a cicatrix remaining after the extensive ulcerations healed. It appears that certain persons have an idiosyncrasy for canned meat. It remains to be learned under what conditions predisposed individuals contract the disease. Charcot has since had occasion to check up other instances of the affection in exploring parties in Greenland and in the small colony of Saint Paul. It is obviously of great importance that the knowledge of this modern scurvy or canned meat disease be disseminated among persons who plan to take long trips into desolate arctic places.—*Bulletin de l'Académie de Médecine,* May 5, 1931.

Constitutional Angiohypotony. — Andrea Ferrannini recalls that in 1903 he described a morbid picture to which he gave the name "chronic arterio-hypotension," though later he preferred "constitutional angiohypotony." During the past fifteen years this condition has been discussed under many different names, the most important being hyposphyxy, arterial hypotony, permanent arterial hypotension, hypotension, habitual hypotony, low arterial tension, and hypotony. Because of the multiplication of nomenclature the identity of this phenomenon has escaped recognition. The outstanding features of the condition are: (1) Signs of lack of tone in the arteries and veins without any corresponding lack in the heart, which in some patients and at some stages is over-excited; (2) severe disturbance in the blood supply and nutrition of the organs, especially the nervous system, kidneys, and liver (3) sclerosis in the walls of the vessels indicating the disturbance in their metabolism caused by the hypotony; (4) general weakness, vertigo, accentuated first sound in the mitral area and accentuated second sound in the aortic area, due to over-excitability of the myocardium, a tendency to displacement of the heart, acrocyanosis without general stasis, oliguria, hematuria, albuminuria, and casts; (5) general alteration in appearance and indication of the influence of general angiohypotony on the development and general metabolism of the body. The morbid picture originates in abnormal constitutional conditions, depending on intoxications and infections *in utero* or during the first years of life, which have affected the development of the body and vascular tissue particularly, especially of the adrenals, pituitary, and thyroid. The treatment should be dietetic, balneological, climatic, and endocrine, in order to tone up and detoxicate the walls of the vessels and the whole organism. The difficulty in the recognition of this constitutional picture is due to the fact that the clinician is accustomed to regard arterial hypotension as a result of myocardial insufficiency and that he automatically looks to the heart whenever he meets a case. As a matter of fact the heart may be in excellent condition and yet the tension of the vessels may be very low.—*The Lancet,* May 23, ccxx, 5621.

LEGAL

CORPORATIONS—LEGAL RESPONSIBILITY OF DIRECTORS

By LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

As a man of prestige and standing in the community, the doctor is frequently sought out and sometimes prevailed upon to accept the position of director of a corporation. The community has confidence in the integrity of the physician, and the addition of the doctor to the personnel of the board of directors of a corporation strengthens the standing of the board from both a financial and personal point of view.

The average man, not versed in the legal consequences of the acceptance of a directorship, may feel and very often does feel that such a position is merely one of honor and may be considered lightly so far as individual responsibility is concerned. Such a view of the consequences of accepting the position of director is highly erroneous. Not only civil liability, but criminal responsibility as well, may result to a director who stands idly by and without protest permits action to be taken which contravenes the civil or the criminal law. The Courts have made it very clear that the duty of a director is to direct, and that he will not be heard to say that he thought the position was merely an honorary one. To be sure, when things go well with the corporation and its affairs are in a prosperous condition the inactive director may lose nothing; but when controversies arise or when the organization becomes involved in straightened circumstances, the result of the failure on the part of any director to be actively concerned and interested in the affairs of the company may and often is the basis of a civil or criminal action against him.

We shall attempt in this editorial and in a subsequent one to discuss some of the legal phases of the position of director.

When a man is elected to a directorship of a corporation, he is not thereby automatically thrust into the responsibilities of the position. He is under no obligation to accept the position if it is not desired by him, and even after accepting the position, if he feels that he has not sufficient time to devote to the position he may resign at any time; nor by becoming a stockholder of a corporation does he bind himself to accept a directorship if offered to him.

Very often men are persuaded against their better judgment to accept the position of director either because of friendship for those in charge of the corporation or because of representations that the individual to whom the position is offered will be a mere "dummy" director and need not worry himself about the affairs of the corporation. It should be remembered that in legal contemplation there is no such thing as a "dummy" director. A man is either a full-fledged director with all the responsibilities that attach to that office or he is not a director at all. In attempting to justify his inaction a board member urged in one of the Courts of this State that he had been acting merely through friendship for one of the stockholders. The Court in rejecting his excuse said:

"As a director, he was chargeable with such knowledge as he gained in that capacity, or might have learned by the exercise of reasonable care. He could not blindly shut his eyes to what was transpiring about him, and shelter himself behind the claim that he was merely acting in the interest of a friend, and knew nothing of what he was doing."

Having taken the office, the Courts have laid down the general rule that a director must act in good faith, without negligence and with reasonable diligence. The rule that a director must act with reasonable diligence is, of course, a question of fact to be determined in the light of all the surrounding circumstances in any given situation. This rule of law is a reasonable rule. A director is not responsible for mere mistakes or errors of judgment if he acts in good faith within the limits of the powers conferred upon him and in the exercise of proper prudence and diligence.

Even though a director does not receive compensation for his services, he is not excused from inattention to his duties. He is not expected, upon assuming office, to possess extraordinary or exceptional ability, but the law places upon him the duty to cooperate in managing the corporation and to devote to its affairs such time as is reasonable in any given case. A director is under the duty of attending meetings of the board, and his continued absence from such meetings without good reason has been held to be evidence of lack of proper diligence. It is well settled that inaction on the part of a director may be held to constitute such gross inattention and unconcern for the corporate affairs as to charge the director with legal responsibility for losses to the corporation caused by such neglect.

Not only from the standpoint of civil liability should a director be alert and active, but it may

be seen from a study of our penal statutes that even criminal responsibility may result from inaction on his part. The law makes a number of wilful improper acts of omission or commission punishable as crimes, and then adds a section which provides in effect that a corporate director is deemed to have knowledge of the affairs of the corporation. Then follows a provision which places responsibility upon directors who fail to attend meetings. This section reads as follows:

"If absent from such meeting, he must be deemed to have concurred in any such violation, if the facts constituting such violation appear on the record or minutes of the proceedings of the board of directors, and he remains a director of the corporation for six months thereafter without causing or in writing requiring his dissent from such violation to be entered on such record of minutes."

In the case of a banking corporation the duty that falls upon a director is much greater. The State very properly takes a direct interest in the welfare of the depositors and clients of our banking institutions. Our penal law says that when an insolvency occurs in an institution of this kind an affirmative duty rests upon the directors, if they are to escape criminal responsibility, of proving that the insolvency was not due to any act or omission on their part. Recently the Court of Appeals was called upon to pass upon the validity of a section of the penal law under which certain indictments had been found for the crime of participating as directors in the fraudulent insolvency of a moneyed corporation. The Court summarized the effect of the statute under which the prosecution was proceeding as follows:

"The insolvency of a moneyed corporation is fraudulent unless its affairs have been administered by its directors fairly, legally and with the same care and diligence that agents receiving a compensation for their services would be bound to observe, and the burden of proof shall be on a director, when insolvency is proved, to show that it was not fraudulent or that he did not participate in the fraud."

In holding that the statute was valid, the Court said:

"The statute appeals to common-law standards of diligence and duty standards to which business men and fiduciaries have accommodated themselves for centuries. It gives warning to directors that they must manage the affairs of a moneyed corporation fairly and legally, and with the same care and diligence that is owing from paid agents, and that if they fail to do this, and by reason of such omission insolvency supervenes, they will be guilty of a misdemeanor. 'Fairly' we interpret as meaning 'in good faith.' * * *

"The test established by the statute, the diligence that is expected of agents in receipt of compensation for their services, is a legislative recognition of a standard of diligence long known to the common law. The diligent director is the one who exhibits in the performance of his trust 'the same degree of care and prudence that men prompted by self-interest generally exercise in their own affairs.' * * *

"The Legislature has said that insolvency shall be classified as fraudulent unless there shall be good faith and obedience to the law and reasonable diligence. The prosecution is not required to prove the absence of all these elements. If that were the requirement, a different conclusion would be necessary. The prosecution prevails (according to the letter of the statute) if it proves the absence of any one of them. This being the definition, the only consequence of eliminating the element of good faith or even the element of compliance with the law is not to increase the defendant's burden but rather to reduce it. By the statute as enacted a threefold standard is prescribed. By the statute as divided the Legislature is deemed to say that if one or more of the standards be rejected as indefinite, the proof shall be confined to the one that satisfies the test of certainty. We are to figure the situation as it will exist at the conclusion of the trial. Let us assume that the People shall succeed in proving that the insolvency is the consequence of a failure on the part of the defendants to direct the affairs of the bank with reasonable diligence. Is it conceivable that the Legislature would have wished such a prosecution to fail because the jury must be told that if due diligence has been exercised, guilt may not be found for transgression of a vague command to run the business 'fairly'? The question carries its own answer."

It cannot be too strongly emphasized that before a physician accepts the position of a director in any corporation, he should be fully aware of the responsibilities that attach to that office. He should carefully consider whether the press of his professional duties will preclude him from accepting such post, but once having accepted it becomes his duty to participate actively as a director. Do not accept the post on the glib representation that you will be a mere "dummy" director or that you need not worry about the affairs of the corporation. Do not permit yourself to be lulled into a sense of false security by the fact that those running the corporation may be your friends. Keep before you always the admonition of our Court of Appeals: "The duty of a director is to direct."

ALLEGED NEGLIGENT TONSILLECTOMY

In this case a young woman consulted the doctor, a specialist in ear, nose and throat cases, complaining of ear trouble. The doctor examined her ear and found that she had otitis media and a catarrhal condition of the left ear. The right ear was purulent, having a central perforation. Also her tonsils were badly diseased and atrophied.

The doctor suggested the removal of the tonsils before anything be done to the ears. To this the patient consented and arrangements were made by which she entered a hospital, and there, under a local anaesthetic, the doctor removed both tonsils. The operation was uneventful and after a confinement of two days in the hospital the patient went home.

She then returned to the doctor's office about once a week for the next ten weeks and each time he irrigated her ears and inserted medications into the ears by applicator. After the said ten visits the doctor heard nothing of the patient for several months, until one day she came to his office and told him she had consulted another doctor who had informed her that a portion of her tonsils had not been removed. The doctor examined her throat and found that the tonsils were completely out and that nothing had grown into the space, but that muscle had worked up a little at the tonsil cavity and that there was a nodule about the size of a pea in the tonsil cavity. This was not diseased and was causing no trouble, but the doctor nevertheless suggested that she allow him to cauterize it. The patient would not consent to be treated that day, but said she would return later. At the time of this visit the doctor noted that her ears had improved but were not entirely healed.

The next the doctor heard of the case was when suit was instituted against him alleging that the defendant did not use proper care and skill in operating upon the plaintiff and removed only a small portion of the tonsils; and succeeded only in scraping and injuring the uppermost portion of the plaintiff's tonsils. The complaint further alleged that as a result the tissues covering and surrounding the plaintiff's tonsils subsequently hardened, making it imperative for the plaintiff to undergo a new operation for the removal of her tonsils, and that as a result of such hardening of the tissues the subsequent operation was especially difficult and painful.

The case was duly brought on for trial before a judge and jury and at the close of the entire case the jury rendered a verdict in favor of the defendant and against the plaintiff.

ALLEGED NEGLIGENT DIATHERMIC TREATMENT

The defendant in this case, a doctor specializing in ear, nose and throat diseases, was consulted by a young woman complaining of headaches. He examined her and found she was suffering from spheno-palatine ganglion irritations. The doctor applied on a swab a 10 per cent solution of cocaine in the ganglion through the nostrils, leaving the cotton in place for twenty minutes before removing it. The patient returned two days later, and appeared to be markedly better but still complained of pain over the frontal sinuses. The doctor then decided to give her diathermic treatment which was administered at his direction by a nurse. The patient was seated in a chair, and a sponge soaked in soap suds was laid on her forehead and held there by an elastic bandage. This was attached to a wire from the diathermic machine. The patient was caused to take hold of a metal rod with her bare hands, which was also attached to the machine, and then the current was turned on. The patient was instructed that if she felt it was getting too warm or if she felt any annoyance to say so and let go of the bar. The patient made no complaint but took a twenty minute 400 M.A. treatment in the usual way, and then went home.

Three days later she came back and the doctor found she had two blebs on her forehead, although at the end of the treatment no redness or indication of burn had been observed. The doctor pricked the blebs, dressed them with a Burrow's solution, and put on a bandage. The doctor called on her daily thereafter for about two weeks and each time applied the wet dressings. There was a sloughing, and when the doctor last saw the patient about a month after the diathermic treatment, the wounds were entirely healed, but there were two small scars on the forehead.

Some time later a suit was started against the doctor charging malpractice in causing the burns, claiming that permanent scars had resulted and that her nervous system had been seriously affected. The action was brought on and was tried twice. The first trial resulted in a dismissal of the complaint at the close of the plaintiff's case. From the judgment entered on that ruling the plaintiff took an appeal, and the Appellate Division ordered a new trial on the grounds that the plaintiff's evidence uncontroverted by the defendant was sufficient to justify a finding of negligence. The suit was retried, and the whole case sent to the jury, who returned with a verdict for the defendant, thereby exonerating him of the charges of malpractice.

NEWS NOTES

COMMITTEE ON PUBLIC RELATIONS

A stated meeting of the Public Relations Committee was held in the Albany office on Tuesday, June 30th, 1931. There were present Doctors Sadlier, Chairman; Fisher, Mitchell, Hambrook, Ross, Johnson, Farmer, and Lawrence.

Lectures to Medical Students: Dr. Sadlier reported that four medical schools had replied to the letter which he had written suggesting that they provide some facilities for acquainting the students before they graduate with the provisions of the new public welfare law. Three of these had requested that Dr. Sadlier provide a lecturer upon the subject. The committee did not think it wise to make a selection, and voted that the chairman should accept the invitation and appoint a lecturer at his pleasure.

Druggists Practising Medicine: Dr. Lawrence reported that the anonymous letter which had been read at the last meeting, containing information concerning the practice of medicine by druggists in New York City and referred to the Five County Coordinating Committee for attention, was referred by them to Dr. Rypins for action. In a response from him he asked for additional information, especially such data as he learned had been collected by investigators of the American Social Hygiene Association. The committee will see that the report of those investigators is put at his disposal.

Illegal Practitioners: Dr. Johnson stated that frequently physicians have asked him what use is being made of the two-dollar registration fee collected annually. These physicians think that the Department of Education could do more with its investigators in the way of discovering and convicting illegal practitioners than is being done at present. Other members of the committee agreed with the observations made by Dr. Johnson, and felt that probably an undue share of attention is being given to New York City, while certain up-state sections are being neglected.

Governor's Health Commission: The committee authorized its Chairman, Dr. J. E. Sadlier, to confer with Dr. Thomas P. Farmer, Chairman of the Committee on Public Health and Medical Education, in regard to carrying out the recommendation made by the House of Delegates, on June first, as follows (see this Journal, July 1, page 828):

"That the House of Delegates instruct the Committee on Public Health and the Committee on Public Relations to study the report of the Governor's Commission, and to make recommendations on all or any of the subjects presented; and that the said Committee report its recommendations to the House of Delegates not later than January, 1932; and that the Council in its wisdom refer this to the House of Delegates either by a special meeting or by referendum of the House. Prior to any action by the House of Delegates a copy of the report shall be submitted to each component county society."

It was informally decided that Chairman Sadlier should give each member of the committee certain portions of the Commission's report to study. It was also decided to invite suggestions from the county societies, and, if necessary, to hold hearings in parts of the State where the county societies desired. (Page 974.)

Public Health Nurse: The influence of the public health nurse as a creator of public opinion was discussed, and it was generally agreed that she has unusual opportunity, and probably greater effort should be made to assist her to bring medical matters properly before the public. Physicians who are entrusted with the care of directing the activities of the public health nurses should keep themselves well informed as to the programs of publicity the nurses are charged with, so that the private physician may not be overlooked as a health agency. It was reported that in many instances the nurses are directing people to seek medical services at public clinics rather than from the family physician. It was also reported from certain counties that public health nurses occasionally undertake to treat patients. These reports dealt particularly with the administration of anti-toxin and toxin- anti-toxin. One report stated that a nurse, at the direction of a health officer, administered anti-toxin to a patient never seen by the health officer. His knowledge of the presence of diphtheria had been received from a report submitted by the laboratory of positive findings. According to law, the laboratory informs the health officer in each district of the positive findings made upon specimens submitted by physicians from patients in his district. In this instance the family physician called as soon as he received the report from the laboratory, but found that the nurse had preceded him and treated the patient. It was the sentiment of the committee that the health officer and nurse had violated the Medical Practice Act in this instance.

Cattaraugus County: A report was received from Cattaraugus County to the effect that a doctor had recently been employed by the County Department of Health as director of maternity, infancy and child hygiene. The physicians

learned first about the matter when the director arrived in the county and began his work. The committee regretted to hear that the county society had been overlooked in a matter of such importance, because it felt that there had been a general agreement between the promoters of the health demonstration and the Committee on Public Relations that no innovation affecting the practice of medicine should be undertaken in any county without the matter would first be presented to the physicians of the county through their Society. The chairman was asked to make an immediate investigation of this matter, and to ascertain why the county society had not been consulted.

Monroe County Society Program: The Committee's attention was called to the elaborate program being developed by the Monroe County Medical Society, looking to effective cooperation of all public health agencies operating in the county, and to the development of an extensive periodic health examination campaign.

J. S. LAWRENCE,
Executive Officer.

STUDY OF HEALTH COMMISSION

The following letter is being sent to the officers of every County Medical Society in New York State:

Dear Doctor:

At the annual meeting of the Medical Society of the State of New York on June 1st in Syracuse, the House of Delegates instructed the Committee on Public Health and the Committee on Public Relations to study the report of the Governor's Special Health Commission, to make recommendations on all or any subjects presented, and to report their recommendations to the House of Delegates not later than January 1, 1932.

Both committees have begun the study, and wish your County Society to know that they are ready to receive for consideration any matter relating to the report which you think should properly come before them. Because of the magnitude of the task imposed upon the committees and because of the lack of clerical assistance, it would facilitate matters greatly if such comments as your County Society wishes to submit be placed in writing, preferably in the form of an abstract.

It is the intention of the joint committee to hold hearings at different places in the state in order that representatives of County Societies who may prefer to appear personally before the committee and discuss particular features of the report in which they have a definite interest, may have such opportunity. Dates and places of these hearings will be announced later.

In the meantime, all communications relating to the work of this joint committee should be addressed to Dr. Joseph S. Lawrence, Executive Officer of the State Society, 100 State Street, Albany, N. Y.

Yours very truly,

THOMAS P. FARMER, *Chairman, Committee on Public Health.*

JAMES E. SADLIER, *Chairman, Committee on Public Relations.*

HEALTH OFFICERS AND COUNTY HEALTH UNITS

The New York State Sanitary Officers Association held a lengthy discussion of the subject of County Health Departments at its annual meeting held in Saratoga Springs on June 30 and July 1 (see this Journal of July 1, pages 909 and 922), and asserted its policy by adopting the following resolution introduced by Dr. Leo F. Schiff, of Plattsburg:

"The New York State Sanitary Officers Association recognizes the benefits to be derived both from an administrative standpoint and for the betterment of public health in rural areas, by the establishment of County Health Units throughout the State.

"We are cognizant of the difficulties of health administration through some one thousand local units, many of them very small; and of the advantages of concentrating administration into a smaller number of larger units.

"We realize that the establishment of County Units will in most cases provide units large enough to carry on an efficient health program in the rural areas. We feel that it would be wiser to attempt to secure county health administration with as little disturbance as possible of the local administration, rather than to attempt to remodel the entire structure of local health administration at one time, for the following reasons:

"1. Local conditions vary considerably in the various counties of this State. No one plan that can be devised will suit all equally.

"2. Many of the present units, though small, are functioning efficiently at the present time.

"We further feel that the concern of the State

Department of Health, both as to concentration of administration and extension of the public health program to rural areas, can be satisfied by the establishment of county health districts without reference to the internal structure of these districts.

"In view of the foregoing, we favor such changes in the Public Health Law as will accomplish the following objects:

"1. The appointment in all counties of a Board of Health, a majority of whose members shall be physicians; excepting that some special provision may be made for the smaller and less wealthy counties, and for the larger cities, towns, villages, and districts which are already well organized.

"2. The appointment of a full-time County Health Officer in each such district by the County Board of Health.

"3. Make permissible but not mandatory the rearrangement of the present structure of health administration within county boundaries.

"4. Providing that all health districts within the territorial jurisdiction of the County Board of Health be responsible to the County Health Officer.

"5. Providing that the County Health Officers and such City Health Officers as are excluded from the county system, shall have complete jurisdiction in their respective territory subject to the advice and supervision of the State Health Department.

"BE IT RESOLVED, that the President of this Association appoint a committee which shall be, and is hereby empowered to take such steps as they may deem advisable to secure the legislative action necessary to carry out the foregoing principles at the next session of the legislature."

All the officers of the Association were re-elected as follows:

President: Dr. Walter Leonard, Cambridge, N. Y.

Vice-President: Dr. M. M. Metz, Williamsville, N. Y.

Second Vice-President: Dr. W. H. Runcie, Freeport, N. Y.

Third Vice-President: Dr. Alexander L. Johnson, Gloversville, N. Y.

Treasurer: Dr. J. W. Crews, Pittsford, N. Y.

Secretary: Dr. Guy H. Turrell, Smithtown Branch, N. Y.

These officers constitute the Executive Committee of the Association.

The members of the Legislative Committee were re-elected as follows:

G. Massilon Lewis, M.D., Vernon, N. Y.; James W. Wiltse, M.D., Albany, N. Y.; Frances E. Fronczac, M.D., Buffalo, N. Y.; William H. Conger, M.D., Poughkeepsie, N. Y.; Arthur D. Jaques, M.D., Lynbrook, L. I.; Hugh H. Shaw, M.D., Utica, N. Y.; Chalmer J. Longstreet, M.D., Binghamton, N. Y.; George E. Ellis, M.D., Dunkirk, N. Y.; William Van Doren, M.D., Mechanicville, N. Y.; James H. Flynn, M.D., Troy, N. Y.; Ralph W. Thompson, M.D., Cornwall-on-Hudson, N. Y.; Leo F. Schiff, M.D., Plattsburg, N. Y.

THE SECOND DISTRICT BRANCH MEETING

An Announcement by the President

The Second District Branch of the Medical Society of the State of New York is composed of the four county societies on Long Island—Kings, Queens, Nassau and Suffolk. It represents a membership of nearly 3,500 physicians, or almost one-fourth of the entire membership of The Medical Society of the State of New York. Geographically it forms a complete unit with common interests, and with boundaries sharply defined by water. Practically it should be the strongest District Branch in New York State.

The officers of the Second District Branch are working hard and putting forth every effort to make this a successful year, and they expect every physician on Long Island to do his part. Therefore start now and reserve the afternoon and evening of November 19, 1931, as the date for the next meeting of the Second District Branch, which will be held in Brooklyn. An excellent program is being arranged—a scientific session in the afternoon, followed by a dinner with speakers of reputation and interest. Doctor William D. Johnson, President of the State Society, as well as other State Society Officers and Chairmen of Committees will be present. Reserve the date now, and do not allow anything to prevent you from attending the largest and best medical meeting which will be held on Long Island this year.

The District Branch is the middle ground between the County Societies and the State Society, and its meetings afford opportunities for the discussion of the broader phases of the practice of medicine, and for a consideration of the future outlook of medicine. We cannot continue the practice of medicine in the same manner as it was practiced a generation ago. The world and civilization have changed, and are constantly changing. New inventions and new medical dis-

coveries make living and social conditions different. Therefore we as a profession must change to meet the new conditions, and above all we must maintain a leadership in all medical activities. This can only be accomplished by an ever-increasing interest in our County Medical Societies, our District Branch Societies, and our State Society.

LOUIS A. VAN KLEECK,
President Second District Branch.

MEDICAL ECONOMICS

The vigorous work of the Committee on Medical Economics last year under the leadership of Dr. George F. Chandler of Kingston has inspired the new committee to plan new accomplishments. While attempting to "carry on" and to further the cooperation with Insurance Carriers in the care of Compensation Law cases, we are hoping to add to the Committee's field of activity in such a manner as will bring to the Medical Society of the State of New York a record for constructive idealism in economic affairs as related to our profession.

The primary essential feature of the Practice of Medicine is the relation of Physician and Patient. This relation has suffered many modifications and complications as a result of various influences operative in recent years. Complexity of social and business conditions; the increasing employment of physicians in public service, in industrial life, in insurance, in public health work, and in hospital administration; the ramifications and abuses of medical charities; the kindly and conscientious interest of foundations in working out scientific problems and providing practical means of enlarging work to promote public health; new laws providing for increased activity of States in public health and sometimes in branches of clinical practice; the increasing tendency of States and even of the Federal Government toward paternalism; the heated magazine propaganda and the publication of books attacking the medical profession for the shortcomings or greediness of the few; the urging of state medicine as the best medical policy; the appointments of lay politicians to newly-made (and old) positions in the public service which can only be competently filled by doctors of medicine; the increase of negligence claim cases; the practice of the medical arts by corporations; the increased number of physicians limiting their work to specialties of varying breadth; the variegated types of hospitals and clinics; so-called "Group practice"; "Medical clubs"; the encroachment upon some types of practice by unlicensed persons—as nurses (anesthesia and industrial clinic work), and physiological chemists (in diagnostic laboratories); the practice of "Fee-splitting" by a certain percentage of the profession; the elaborate costs of equipment and transportation; the advances of therapeutic propaganda by manufacturers of remedies; the gratuitous study of the cost of medical care by a self-constituted commission with generous financial backing; all of these and other influences have modified and complicated the relation of physician and patient.

Your committee starts its work by assuming that all sane "Medical economics" should be built upon two basic principles—service of high quality, and a reasonable compensation for the worker. We assume also that there have been reasons for the development of all of the above mentioned factors (and many more) which have modified and complicated modern practice, often with injustice to the physician, quite as often with injustice to the patient or the public.

A survey of all of the fields of activity occupied by physicians and of all of the economic relations of the profession seems to be needed. Such a survey cannot be accomplished by a committee of the few. Some of the constituent County Societies have local Committees on Medical Economics. We shall need their assistance and urge their cordial and prompt cooperation in our survey. In those county societies where no such standing or special committees exist we request the early appointment of such committees, to be ready to cooperate with us.

We must first know *the facts.* In the Empire State what one, five, or ten men can find all of the facts? Our State is large. Communities vary in size and in the character and the conduct of lives and in medical practice as related to those lives. Hence the need of widespread assistance in any comprehensive survey.

When the facts are in hand, classified, and tabulated—a careful study can be made. Such a study, thoughtfully conducted, should lead to recommendations and perhaps laws, which would benefit all of the people and lead to increased and deserved confidence in our profession.

CHARLES H. GOODRICH, *Chairman.*

ANSWERING MEDICAL LICENSING EXAMINATION QUESTIONS

Dr. Paul B. Brooks, a member of the New York State Board of Medical Examiners, after rating several hundred hygiene papers following a recent licensing examination, has asked the Journal to print the following practical suggestions and requests that physicians pass them on to future candidates in whom they are interested:

"Be sure you understand the questions. Devote more time to thinking, and less to writing.

"Answer questions fully, but also briefly and concisely. If you know the answers, few words will be required, as a rule.

"Don't throw in information not called for. It makes extra work for the examiner and may be incorrect.

"Don't attempt to conceal ignorance in a mass of useless verbiage. It can't be done.

"Use simple language. Don't try to make an impression by using big words or referring to personal experiences, as "On my service at the Blank Hospital, we, etc." If you make an impression, it may not be the sort you are hoping for.

"Remember that an examiner with a large number of papers to rate does not want to waste time "digging around" in an effort to find out whether or not the candidate really knows the answers.

"The purpose of licensing examinations is not to determine whether or not the candidate knows the answers to certain questions, but rather to ascertain whether or not he is capable of practicing medicine intelligently."

ALBANY COUNTY

The May meeting of the Medical Society of the County of Albany was held at the Laboratory of the New York State Department of Health on Manday evening, May 18, 1931.

The Society went on record as not accepting responsibility for pre-school clinics in Albany County, but would be glad to see such work continued as in the past inasmuch as it does not interfere with private practice. The Secretary was instructed to inform the State Department of Health of our attitude in this matter.

Dr. Arthur M. Dickinson read resolutions on the death of our late member, Dr. Wesley A. VanDeusen. These resolutions were accepted and spread upon our minutes and a copy sent to the family of the deceased.

The Scientific Program was furnished by the Laboratory Staff of the New York State Department of Health and consisted of the following interesting papers:

The Laboratory Service of the State, by Augustus Wadsworth.

"Undulant Fever," by Ruth Gilbert.

"Recent Studies Relating to Diphtheria," by Mary B. Kirkbride.

"Problems in Serum Therapy," by Augustus Wadsworth.

Following presentations of formal papers demonstations were held in various departments of the Laboratory.

Visitors were present from Troy, Schenectady, Amsterdam, and other surrounding counties.

Through the courtesy of Dr. Wadsworth a light luncheon was served following the meeting.

The total attendance at this meeting was about 130.

HOLMER L. NELMS,
Secretary.

GREENE COUNTY

The regular July meeting of the Greene County Medical Society was held at the Mountain House at Haines Falls on Tuesday evening, July 14th, with the President, Dr. M. H. Atkinson, in the chair. A dinner preceded the meeting, many of the members having brought their wives and other members of their families to this famous mountain resort.

Dr. Thomas Earl McQuade of Coxsackie was elected to membership.

Dr. Stuart B. Blakely of Binghamton, N. Y., delivered a most interesting address on Personal Experiences in Soviet Russia with particular reference to obstetrics. This address was something out of the usual and was most instructive, Dr. Blakely having visited Russia at two different times.

Dr. James E. Sadlier, of Poughkeepsie, Chairman of the Public Relations Committee of the State Medical Society, made clear the work of the State Committee, and urged the active support of the County Society Committee.

The following nominations were presented by the nominating committee for election at the annual meeting in October:

For President—I. E. Van Hoesen of Coxsackie.

For Vice-President—Kenneth Bott of Greenville.

For Secretary—William M. Rapp of Catskill.

For Treasurer—M. H. Atkinson of Catskill.

For Ch. Legislative Comm.—P. G. Waller of New Baltimore.

For Ch. Pub. Health and Pub. Relations—A. B. Daley of Athens.

For Delegate to State Soc.—F. W. Goodrich of Catskill.

For Alternate—R. E. Persons of Cairo.

For Delegate to 3rd Dist. Br.—W. M. Rapp of Catskill.

For Alternate—L. B. Honeyford of Catskill.

Dr. A. B. Daley, of Athens, Chairman of the Committee on Public Relations, reported the results of a recent conference of his committee with the Public Health Nursing Committee of the Board of Supervisors, and stated that this Nursing Committee had proposed that the Medical Society of Greene County formulate a working plan for the cooperation of the two committees. Dr. Daley was instructed to have the Public Relations Committee formulate a plan and submit it to the County Society for approval, and then to submit it to the Public Health Nursing Committee.

WILLIAM M. RAPP, *Secretary.*

ERIE COUNTY RADIO TALKS

The Erie County Medical Society will continue the program of radiograms which were described in this Journal of February 15, 1930, page 236, and the issue of November 1, 1930, page 1308. The Society has a Committee on Radio Health Talks consisting of twenty-three members, of which Dr. H. G. Johnson is chairman. The Committee has issued the following circular letter to the members of the County Society:

"The Medical Society of the County of Erie has instituted a new method of Radio Broadcasting, beginning July 1, 1931. The program will be given over Station WGR, Buffalo, from 5:45 to 5:55 every Monday, Wednesday and Thursday afternoon.

"The subject matter will be presented in a popular manner, and it is hoped you may be able to interest your patients in becoming constant listeners to these talks on preventive medicine.

"Pursuant to a vote of the Society at the May meeting, two physicians with suitable radio voice have been engaged for this feature of medical education of the public. There will be no announcement of the name of the doctor who is speaking. This is a radical departure from the previous system, and it is the sincere hope of the Committee that you will cooperate with the Society by interesting yourself and your patients in these broadcasts as a means of improving community health.

"A copy of the program for the next two months is enclosed. May we ask that you hang it in a conspicuous place in your waiting room.

"Your suggestions and criticisms will be appreciated."

The program is printed on a card, perforated for hanging in the doctor's office, and reads as follows:

JULY 1—"How Are You."

JULY 2—"Casualties of the 4th of July."

JULY 6—"What You Don't Know."

JULY 8—"The Unseen World."

JULY 9—"Concerning Germs."

JULY 13—"The Romance of Vaccination."

JULY 15—"The Romance of Vaccination."

JULY 16—"The Romance of Vaccination."

JULY 20—"This Matter of Reducing."

JULY 22—"This Matter of Reducing."

JULY 23—"This Matter of Reducing."

JULY 27—"Dame Nature's School."

JULY 29—"Sanitation of Automobile Tourists' Camps."

JULY 30—"Some General Dietary Hints."

AUG. 3—"Hot Weather Suggestions."

AUG. 5—"The Way of the Vegetarian."

AUG. 6—"What's the Matter With My Nose and Throat."

AUG. 10—"The Prevention of Hay Fever and Asthma."

AUG. 12—"Little Glands with Big Jobs."

AUG. 13—"Little Glands with Big Jobs."

AUG. 17—"The Genealogy of a Germ."

AUG. 19—"The Unseen Enemies of Children's Health."

AUG. 20—"The Unseen Enemies of Children's Health."

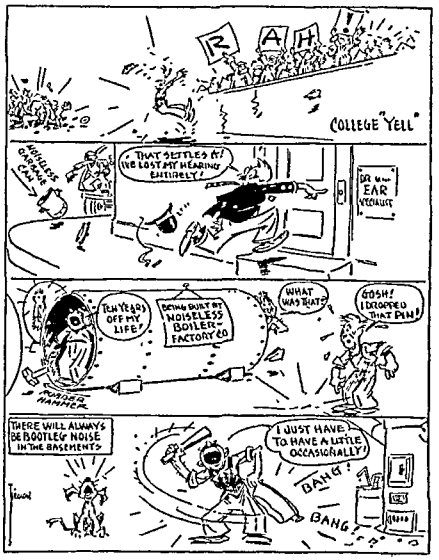
AUG. 24—"The Truth Shall Make You Free."

AUG. 26—"Smith in Search of Health."

AUG. 27—"Smith in Search of Health."

AUG. 31—"Why a Child Is Always Hungry."

THE DAILY PRESS



ASH CAN NOISE

The New York City newspapers of July first carried many accounts of the official tests of a new silencer for ashcans. The *Herald Tribune* said editorially:

"We feel a shy relief that the ultra-modern, rubber-tired ashcans tried out by the city's noise experts failed of their purpose. One rubber-tired ashcan bounced so merrily that it fell over on its unrubbered side, making more noise than the common or back-yard variety. Another, apparently excited by the unwonted competition, shed its rubber clothes completely and reverted to its natural noisy normalcy. The net result of the experiment was the super-scientific deduction that a noiseless ashcan is precisely five pin-drops more silent than a creaking can of the old-fashioned species.

"So, for the present at least, ashcans are still ashcans. Just as the subway is still the subway, and steam riveting is still steam riveting. New York is still New York. We are content; if all the din disappeared, if ashcans were gentle and even the air were sifted, what excuse would be left for fleeing to the country each week-end?"

The items on noise abatement carried by the New York dailies have been unusually well written. They compel attention by their intrinsic interest, and their content is scientific and truthful. Even the cartoons are editorials.

From the N. Y. Herald Tribune, July 9, 1931

THE NEGRO METROPOLIS

The *New York Herald Tribune* of July 7 has an editorial on the negro metropolis of the world which it locates on the northern end of Manhattan Island with its 225,000 negro population. The editorial says:

"Harlem is a mushroom growth, but the New York negro looks back with pride on a long participation in the history of Manhattan Island. Eleven negroes landed in New Amsterdam in the first year of its colonization, 1626; and by the end of that century 2,170 negroes lived in New York—5 per cent of its population. It was a free negro, Samuel Fraunces, who gave his name to Fraunces' Tavern, where General Washington dined and where New Yorkers are proud to eat today. New York City had free schools for negroes before it had free schools for whites. And in recent years New York has been the home of many of those superb negro artists who have written new chapters in the history of art in America—men like Charles Gilpin, who won his fame here in "The Emperor Jones"; Richard Harrison, whose Lord God Jehovah has startled onlookers at "The Green Pastures"; Countee Cullen and Langston Hughes and James Weldon Johnson and other poets and novelists; singers like Roland Hayes and Paul Robeson, scores of others known wherever the international language of art and music reach.

"To such men Harlem is, or has been, home; and New York is to negroes all over the world today something of what Rome was to the old Roman world and Athens in its heyday to Greater Greece. To some New Yorkers "Harlem" still means only a region of dark-skinned night clubs and a lodging-house for elevator boys and household servants; others are proudly aware that Harlem is the capital of a race and the seat of a culture."

The writer might also have commented favorably on the negro physicians of whom over two hundred are practicing scientific medicine in Greater New York.

AGES OF THE NEW YORK CITY DWELLERS

The ages of the people must be considered in comparing one city or country with another. The tendency is for parents with small children to live in the rural suburbs and to commute to their work in the city; and for people beyond the working age also to live in rural districts on account of the increased comfort and decreased cost of living. Thus it happens that New York has become a city with persons in the vigor of their manhood, while the babies and old people live elsewhere. The New York *Times* of July 15, commenting on these ages, says:

"A decrease in the number of small children in New York City is one of several striking facts revealed in data concerning the ages of residents of the city, made public today by the Census Bureau. The number of children in the city under the age of 5 years was 560,869 in 1920 and 535,600 in 1930, a decline of 25,269.

The number of children under one year of age was 108,908 in 1920 while the total in 1930 was only 100,398.

"All other age groups showed increases during the decade.

"Speaking in a general way New York is a city of youth.

"Of the total population of the city, 24.3 per cent are under 15; 18.5 per cent are from 15 to 24; 35.8 per cent are from 25 to 44; 17.3 per cent are from 45 to 64 and 3.9 per cent are 65 and over.

"By combining groups it is made plain that three-fourths of the inhabitants of the city are under 44 years of age.

"The number in the various age groups are as follows:

Age	1930	1920
Under 5	535,600	560,869
Under 1	100,398	108,908
5 to 9	577,284	536,490
10 to 14	575,300	494,867
15 to 19	599,286	453,758
20 to 24	687,417	545,650
25 to 29	695,984	575,915
30 to 34	649,576	513,204
35 to 44	1,139,836	853,636
45 to 54	762,870	585,683
55 to 64	436,804	315,930
65 to 74	204,683	130,950
75 and over	59,820	45,281
Unknown	5,986	7,805

"On a percentage basis, persons in the age groups from 15 to 24 years and from 30 years upward represented a larger proportion of the total population in 1930 than in 1920, while for those in the age groups under 15 years and from 25 to 29 years the proportion was smaller than in 1920."

MAGICIANS FIGHT FORTUNE TELLERS

Magicians are legitimate entertainers who perform mystifying tricks, but disclaim any mystical or super-human power. They are scientists who seek to expose deceit in fortune tellers and others like them. The New York *Times* of July 15 has the following account of the offer made by the magicians to help expose the fortune telling fakers:

"What was described as the first step in an aggressive campaign to rid the city of fortune tellers, palmists, numerologists, soothsayers, clairvoyants, mediums and similar quacks was taken yesterday when Julian P. Proskauer, trustee of the Society of American Magicians, sent a letter to Police Commissioner Mulrooney offering the cooperation of the organization in discovering and prosecuting such persons.

"According to John Mulholland, first vice-president of the society, which for the last year has been conducting an educational campaign against fortune tellers, the organization was aroused by the recent suicide in Chicago of Mrs. Sarah Koestner, which was induced, news dispatches indicated, by the ominous predictions of a fortune teller.

" 'Fortune tellers and their kind break up more homes in the United States than any other one cause,' Mr. Mulholland, who has studied the machinations of the quacks for ten years, explained. 'People only go to such persons to get answers to two questions; questions about love and money. Fortune tellers have found that plain matter of fact answers do not interest their clients, so they tell them their wife or husband is interested in some other person and thus sow the seeds of jealousy, or else they predict some dire happenings.

" 'The public pays an annual fee of $125,000,000 to these racketeers, of which about $25,000,000 is spent in New York City, while the Chicago soothsayers receive annually about $10,000,000. There are about 125,000 of their breed in the United States, about half of whom are in New York.' "

BOOK REVIEWS

THE TREATMENT OF CHILDREN'S DISEASES with special formulas and drugs for childhood, and a short diagnostic summary of each clinical picture. By Prof. Dr. F. Lust. Authorized translation of the sixth German edition with additions by Sandor A. Levinsohn, M.D., Octavo of 513 pages. Philadelphia and London, J. B. Lippincott Company, 1930. Cloth, $8.00.

The reviewer can find very little in this book, either as a text or reference work, that deserves his recommendation.

The translator deserves great credit for his corrective footnotes. He would have done better had he omitted the author's treatment and substituted his own instead. The chapter on Appendicitis, is not only obsolete but if the method, the book teaches its readers to follow, were adopted, in the majority of cases, would prove disastrous to patient and Pediatrician alike.

The article on Diphtheria is not worthy of a modern work. The treatment of Hypertrophied Tonsils is twenty-five years behind the present times and accepted methods of to-day. The reviewer finds it very unpleasant to give this unhappy criticism of a work by which the translator has done so well and for which he deserves great credit.

HARRY APFEL.

ABNORMAL PSYCHOLOGY: Its Concepts and Theories. By H. L. HOLLINGWORTH, Ph.D. Octavo of 590 pages. New York, The Ronald Press Company, 1930. Cloth, $4.50. (Psychology Series.)

This book by Hollingworth will interest the average family physician. It gives a comprehensive review of defectiveness, the neuroses and psychoses. The writer, who has been a teacher at Columbia University for years, is known as a very close student of his subject. There is little else except praise to say of his book, excepting this: He has not drawn as fully as he might have from the psychoanalytic literature. He gives too much credence to Rosanoff's views on hysteria, which are not accepted by many psychiatrists. His failure to refer to workers like William Healy and Paul Schilder will probably be corrected in a later volume.

J. F. W. MEAGHER.

A SYSTEM OF BACTERIOLOGY IN RELATION TO MEDICINE. By Various Authors. (Prepared under the direction of the Medical Research Council.) Volume VI. Octavo of 538 pages. London, His Majesty's Stationery Office, 1931. Cloth, £8-8-0 a set; £1-1-0 each.

The entire volume of 535 pages is devoted to the subject of immunity. This, of course, makes possible a more detailed and extended discussion than is given in the usual texts on bacteriology. The various phases of immunity are presented in chapters on natural immunity, active immunization with toxin, antigens and antibodies, hemolysis, complement, opsonins, agglutination, precipitation, ferments, allergy and finally the relation of colloids to immunity and a short chapter on chemotherapy. In each chapter all important research on that subject from the beginning to the present time is summarized. In certain branches the volume of research has been very large. For example, the discussion of antitoxin covers 80 pages.

This is an excellent reference work on one of the most complicated subjects in medicine. E. B. SMITH.

AN INTRODUCTION TO PRACTICAL BACTERIOLOGY: A Guide to Bacteriological Laboratory Work. By T. J. MACKIE, M.D., D.P.H., and J. E. MCCARTNEY, M.D., D.Sc. Third edition. 12mo of 421 pages, illustrated. New York, William Wood & Company, 1931. Cloth, $3.50.

The original character of the book has been maintained in the new edition. Only those new subjects which are useful as a guide to practical bacteriology have been added. To avoid expansion, however, the authors have discarded those sections which time has shown to be of less practical value, and replaced them with newer and more practical information.

SILIK H. POLAYES.

METHODS AND PROBLEMS OF MEDICAL EDUCATION. (Eighteenth Series.) Quarto of 329 pages, illustrated. New York, The Rockefeller Foundation, 1930.

This volume contains the usual well-illustrated descriptions of medical school teaching units from various parts of the world. An especially instructive article on the photography of gross pathological specimens, written by W. G. MACCALLUM, is included. This may also be found in the *Bulletin of the Johns Hopkins Hospital* for March, 1929. It deserves wider reading. C. A. G.

THE DIET BOOK FOR DOCTOR, PATIENT AND HOUSEWIFE with specimen menus for one week and recipes. By MARGUERITE REQUA REA. 12mo of 197 pages. New York and London, Oxford University Press, 1931. Cloth, $2.75.

This is a practical book giving without theoretical consideration the actual diets for a number of diseases. It gives in detail what the patient is allowed to eat and what is forbidden. In the majority of instances a menu is given for one week with each dietary.

In Part Two, cooking instructions are given with tables of measures and weights, time required for digestion of various foods, food values and many recipes original with the author or tried by her in her work. The combination of diet lists with the detailed methods of actually preparing them is unusual and is a very convenient arrangement. W. E. MCCOLLOM.

EASIER MOTHERHOOD: A discussion of the abolition of needless pain. By CONSTANCE L. TODD. 12mo of 199 pages. New York, The John Day Company, 1931. Cloth, $2.00.

This volume is written by a layman for the laity, and apparently, it is the author's intention to instruct women concerning the various means of relieving the pains of childbirth so that they will demand from their doctor as much relief as possible during labor.

The book is written in simple language, which most women may easily understand, and the author has studied her subject deeply. She devotes much space to the Gwathmey Ether and Oil Analgesia, and she also notes the various other standard methods by which the pains of childbirth may be partially alleviated. She indites, in no uncertain terms, not only the elective version, but also those of the medical profession who do not give their patients proper care or proper relief of pain during labor. The book is worth reading by the profession, for it shows us the woman's point of view; it is worth reading by women, for it tells them what may be done to give them relief, and it may, as the author hopes, create a demand for the relief of the pains of labor, in localities where obstetrical analgesia is not practiced.

W. S. S.

OUR NEIGHBORS

HOUSE OF DELEGATES OF TEXAS

The June issue of the *Texas State Journal of Medicine* has seventy-three pages devoted to the proceedings of the House of Delegates which met on May 4-7, 1931, in Beaumont. The printed transactions include the reports of the officers and committees, and the action taken on their recommendations. The transactions are unusually clear, and one reading them carefully will get a clear conception of the scope of the activities of the Society.

The Secretary, Dr. Holman Taylor, reported 3329 members of the State Association, a loss of 170 from last year when the number of members was the largest ever listed. The Reference Committee, commenting on the number of members, said:

"The outstanding fact presented for your consideration in this report is that out of 11,000 regular physicians, licensed to practice medicine in Texas, there are at this time, only 3,329 members of the Texas State Medical Association. In other words, less than one-third of the legally qualified practitioners of medicine in Texas are now affiliated with the State Medical Association. This is, indeed, a pitiful showing, when we consider the very essential service rendered by organized medicine in Texas, not only to the doctors, but to the public as well.

"In seeking an answer for this condition the suggestion most frequently found was that the dues were probably the most decisive factor in determining the membership or non-membership in the County Society and State Association. Just how seriously this factor operates is, of course, impossible for your committee to properly evaluate, and yet it is the consensus of opinion of this committee that it is a definite and tangible factor."

The annual dues of the State Association have been ten dollars, but the House reduced them to eight dollars, although the proposed new dues was six dollars. The allocation of the dues, according to the by-laws, will be as follows:

To Medical Defense	$1.00
To Journal subscription	3.00
To general fund	4.00

Although the dues were reduced, the House voted to increase the salary of Dr. Holman Taylor, the Secretary, twenty-one years in office, to $10,000, although he is receiving $4,000 at present.

The financial report shows that the total receipts of the State Association from all sources is $64,359.95, of which $4,564.87 is from interest on reserve funds of about $71,000, as nearly as can be determined from the report. One argument for the reduction of dues was that the reserve fund was intended for use during times of financial depression as at present.

Donations to the funds and reserve of the Association are authorized by the Constitution, Article XIII, Section 4, which reads:

"The Trustees shall have the authority to receive volunteer contributions, for specific or general purposes, and shall dispose of said contributions in accordance with the terms of the donors, or its own judgment in the instance there are no such terms."

This provision is in contrast with the policy expressed by the House of Delegates of the Medical Society of the State of New York, not to accept financial donations.

The two-dollar reduction of dues is the same as the fee under the annual registration law which was adopted by the Legislature last winter. The Association had previously allocated about one dollar per member to the prosecution of illegal practitioners, and will continue that appropriation this year, for the registration law takes effect at the beginning of next year. The Association acts by assisting the local societies in prosecutions,—employing a full-time investigator for the purpose. During the last year, 101 cases were prosecuted by the State Association. This activity will be assumed by the Board of Medical Examiners next year.

The following editorial describes the work of the legislative work done by the Executive Council:

"The report of the Executive Council covers in great detail the successful passage of the two major measures of the Association in a legislative way, namely, the bill carrying amendments to the Medical Practice Act and its companion bill that provides for annual registration of practicing physicians.

"The provisions of the two measures are, we feel sure, well known to our readers. Suffice it to say here, that our State Board of Medical Examiners is now permanently organized, with an overlapping, long-time term of office for its twelve members, and with the right, and the money, to employ a permanent office and field force, and proceed in the enforcement of the Medical Practice Act. In addition to that, there will now be a central place of registration for

(*Continued on page 984—Adv. xiv*)

BOBBY JONES' CHAMPIONSHIP GOLF CLUBS

These are the matched clubs with which Bobby Jones retained the amateur golf championship.

IN GOLF, THE CLUB IS ADAPTED TO THE SHOT. IN INFANT FEEDING, THE DIET MATERIAL IS ADAPTED TO THE INDIVIDUAL REQUIREMENT OF THE INDIVIDUAL BABY.

IT IS possible to play over the entire course with a single club and bring in a fair score. But playing with only one club is a handicap. The best scores are made when the player carefully studies each shot, determining in advance how he is going to make it, then selects from his bag the particular club best adapted to execute that shot.

For many years, Mead Johnson & Company have offered "matched clubs", so to speak, best adapted to meet the individual requirements of the individual baby.

We believe this a more intelligent and helpful service than to attempt to make one "baby food" to which the baby must be adapted.

Dextri-Maltose No. 1 (with 2% sodium chloride), for normal babies. Dextri-Maltose No. 2 (plain, salt free), for salt modifications by the physician. Dextri-Maltose No. 3 (with 3% potassium bicarbonate), for constipated babies. "Dextri-Maltose With Vitamin B" is now available for its appetite-and-growth-stimulating properties. Mead's Powdered Non-Curdling Lactic Acid Milks, Nos. 1 and 2. Mead's Alacta. Mead's Powdered Whole Milk. Mead's Powdered Protein Milk (Non-Curdling). Mead's Recolac. Mead's Sobee. Mead's Powdered Brewer's Yeast. Mead's Cereal. Mead's Viosterol in Oil 250 D. Mead's 10 D Cod Liver Oil With Viosterol. Mead's Standardized Cod Liver Oil.

POISON IVY EXTRACT

LEDERLE

for the treatment of Rhus Dermatitis

POISON Ivy Extract (Lederle) is a solution of the purified toxins of Rhus toxicodendron in almond oil. The efficiency of this product has been demonstrated by its clinical use throughout the country during the past six years. This almond oil extract possesses the advantages of being non-irritating and its injection, therefore, does not cause severe reactions or pain.

POISON IVY EXTRACT (Lederle) is supplied in packages of four syringes containing 1 c. c. each, and in single syringe packages.

Literature upon request.

LEDERLE LABORATORIES

NEW YORK

(Continued from page 982)

every doctor in the state of Texas who is authorized to practice medicine, with an annual check-up on credentials.

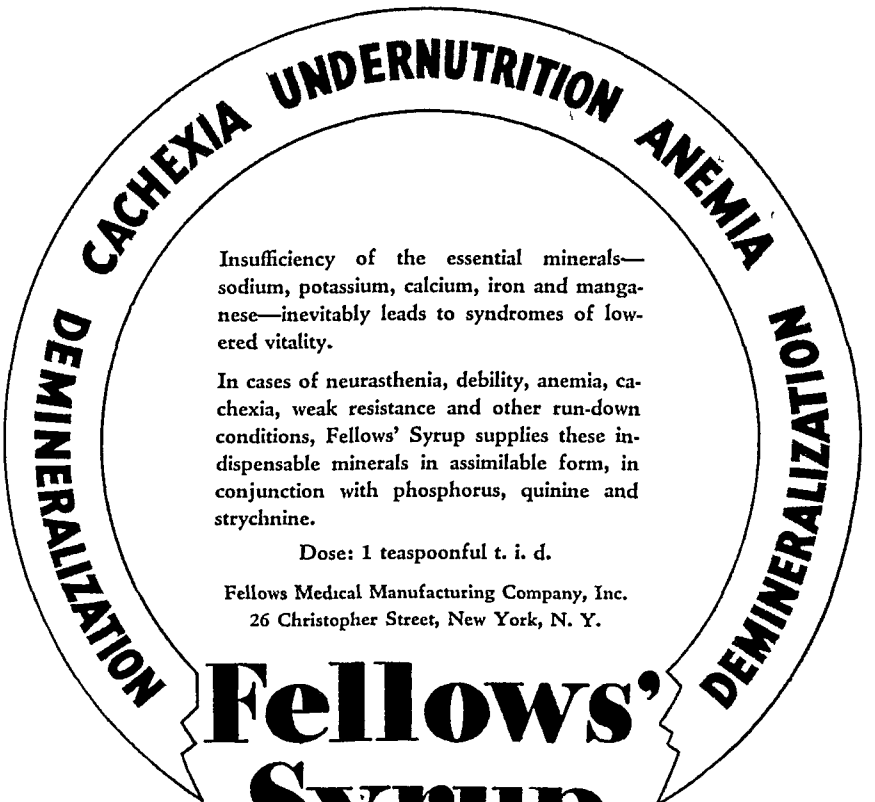
"We note with much interest the failing strength of chiropractors and christian scientists. It is our conclusion that the influence of these two very hurtful groups has faded away in proportion to the amount of education received by the members of the Legislature and by the public. It is our opinion that the endeavors of health workers to secure this helpful legislation has gone much further than that; it has served to educate the public on the very serious problem of the practice of medicine."

The minutes of the House of Delegates devote two pages to records of the votes of each member of the Legislature on each roll call relating to medical laws.

To read the seventy-three pages of the transaction is quite a task, with its nine columns of records of the election of officers and a half column of the Chaplain's prayer; yet the Journal says editorially:

"It is through the study of these transactions, and that way only, that a member of the organization may be informed as to its status. The report may appear to be long, and it is long, and perhaps it is not attractive reading on the face of it, but we assure our readers that it is most interesting and that if any will start in to read it the chances are they will finish the task."

The members of the Medical Society of New York State will be interested in the manner in which their Texas brethren conduct their annual meeting and other affairs, but they would consult the transactions with the greater profit if an index and cross references were added, as they are to transactions printed in the NEW YORK STATE JOURNAL OF MEDICINE of July first.



PRESIDENT'S REPORT IN CALIFORNIA

The June issue of *California and Western Medicine* contains the report of the California Medical Association given to the House of Delegates, April 27. President Lyett C. Kenney makes the following suggestions:

"The county medical society should educate its members in present economic problems. They should know what forces are molding public opinion and what changes are being demanded in medical practice. They should also be informed concerning the real facts in the cost of medical care and the relation of these costs to the individual and to the public as a whole. The county society should study the economic problems in its own community to determine what adjustments are necessary to meet modern needs. Our members should come to realize that the financing of medical service is but incidental, and

(*Continued from page 984—Adv. xiv*)

that the real problem is to provide all classes with qualified medical care. The county societies should place as much emphasis on the study of these economic problems as they do on scientific and clinical medicine.

"The county medical society should put new emphasis on public health education. We *can* mold public opinion, but we have made very little organized effort to do so. The public is greedy for health education, and we cannot blame people if they are influenced by the vast amount of misinformation they receive. A Speakers' Bureau in the county society should be prepared to place speakers on health and medicine wherever they can be used.

"The Society has a dynamic force for public health education in our magazine, *Better Health*. With very little effort the county society can place this magazine in 50,000 homes in California and on the reading table of every club and library.

"The county medical society can lead and direct in all public health activities. The profession has hitherto either ignored or strongly criticized health activities by the state or lay organizations on the grounds that they interfered with private practice. Public opinion is behind these activities which are attempting to do the work of the community that the medical profession has not provided.

"The county medical society should be prepared to *direct* in health and medical legislation. The influence of the county unit is essential in legislative crises at Sacramento, but its legislative contacts should not be limited to the two months of the biennial session. The society should maintain continuous contacts with the legislators, and so establish confidence and respect for the judgment and requests of the medical profession.

"The California Medical Association should develop immediately a definite, detailed plan of public relations for the county medical societies. This involves a survey of the particular needs of this state and of the activities of other state associations. This program should include methods of public education and the providing of material therefor. It should include plans for advisory contact with all health officials and cooperation with all lay welfare organizations.

"In the near future the California Medical Association should employ a well trained executive to develop this program in and with the county societies. Under the present provisions of our Constitution the title might be that of 'Executive Secretary in Charge of Public Relations.' His duties should be to cooperate with the standing committees and carry out plans and policies which are directed and approved by the council.

"It is the custom in several states to grant the president a page each month in the journal of

(*Continued on page 987—Adv. xvii*)

(*Continued from page 986—Adv. xvi*)

he Association in order that he may bring to the nembers a frequent personal message. I respectully suggest that the California Medical Associaion adopt the policy of a President's Page in *Calfornia and Western Medicine.*

"I suggest for your consideration the formaion of a permanent Cancer Commission by the California Medical Association. This commision should be appointed by and report to the Council and should consist of the outstanding eaders in the pathology and therapy of cancer. The function of the commission should be to provide means for the education of the medical profession in the early recognition and diagnosis of cancer. It should also cooperate with the American College of Surgeons and the American Society for the Control of Cancer in developing a definite cancer program for California. This s a vital public health interest that should be led by the medical profession rather than controlled by the laity or the state."

These suggestions were "commended" by the reference committee.

JOURNAL OF CALIFORNIA

The report of Dr. George H. Kress, Editor of *California and Western Medicine,* to the House of Delegates of the California Medical Association on April 27, is printed in the June number of the Journal. Concerning the increasing number of papers read before the State Society, the following report reflects the policy of the NEW YORK STATE JOURNAL OF MEDICINE:

"The question arises whether or not more papers are being read at the annual sessions of our State Association than heretofore or whether too large a number of papers read before county medical societies have been accepted for publication. In answer to this it may be stated that it is both desirable and necessary that *California and Western Medicine* shall be something more than a so-called 'Annual Proceedings' volume, even though printed in twelve monthly installments. The official publication of the California Medical Association is not solely intended to put into printed form every paper presented at an annual session. In the matter of special or original articles, it should be a medical journal published under state medical association auspices, in the pages of which can be found a presentation of worthwhile work and investigation carried on by California physicians in all the fields of medicine and surgery, and its contents should be also of such nature to not only be of interest or of use

(*Continued on page 988—Adv. xviii*)

...There is a reason why Pil. Digitalis (Davies, Rose) have become the choice of Cardiologists...

. . . They are digitalis in its completeness—physiologically tested leaves in the form of physiologically standardized pills, giving double assurance of dependability.

. . . Each pill contains 0.1 gram, the equivalent of about 1½ grains of the leaf, or 15 minims of the tincture.

. . . Convenient, uniform, and more accurate than tincture drops.

Sample and literature upon request.

to those members who may have been present at the preceding annual session, but particularly be of service to that very much larger number of members who are not so fortunate as to have been in annual session attendance.

"The number of annual session papers which are on hand and which have not been published at the opening of a succeeding annual session has been increasing year by year. This increase has been due to the larger number of sections and to the fact that some sections have a much larger number of papers on their programs than the average of other sections. The Executive Committee has considered this new problem, and in the effort to solve it to the best interests and satisfaction of all concerned, the rules laid down in this year's official program have been adopted, in the hope that the number of unpublished papers on hand at the beginning of a succeeding annual session may be considerably reduced. It must be conceded by all that annual session papers should all be printed within or almost within the succeeding twelve months."

Concerning the finances of the Journal, the Treasurer reported:

"The income of *California and Western Medicine* derived from advertising was $37,070; from allocated county society dues, $9,688.50; from the subscriptions, $2,829; and from sales of review books, $180; making a total income of $49,767.

"The expense of the Journal, including production, distribution, promotion and selling expense, totaled $37,132. The salaries of the editors and one-third of the clerical expense amounted to $12,473; the general expense, $4,249; a total of $53,858. The total income being $49,767, the loss for the Journal was $4,088. Deducted from the $14,162 gain made by the general office, the net income of the California Medical Association for 1930 is $10,074."

Commenting on the report of the Treasurer, the editor says:

"Turning now to the financial side of *California and Western Medicine,* the picture in this year of economic depression and financial hard times is not so good as a year ago. During this last year the advertising income fell off from $40,098.86 to $37,070.73, making a loss in advertising income for this last fiscal year of $3,028.13.

"The printing, production and distribution costs of the Journal last year were $29,012.42 and in the present year were $30,537.85 or an increase in these costs of $1,525.43. This is explained in part by somewhat larger issues, brought out in an effort to bring more of last year's annual session papers off the press. The editorial and clerical

salaries have remained practically the same, the increase for this last year amounting to $104.33 One-third of the general expenses of the central office and of the Association are also charged against the official Journal account. These general expenses are larger than heretofore because the new central offices of the Association pay a considerably higher rental and because the annual session expenses this year are also twice as great as last year."

The Editor also comments on the commercial exhibit at the annual meeting, and reports that only advertisers are allowed to purchase space in the booths.

AN EARLY DIAGNOSIS CAMPAIGN IN WISCONSIN

The June number of the *Wisconsin Medical Journal* describes an Early Diagnosis Campaign conducted by the Outagamie County Medical Society for the examination of the high school students of Appleton. The report says:

"During the last two weeks in April the Outagamie County Medical Society in conjunction with the Appleton Woman's Club sponsored the Early Diagnosis Campaign conducted by the Wisconsin Anti-Tuberculosis Association. Through this organization of forces, the Medical Society was able to carry on a far-reaching and effective piece of work. These dozens of people working together were better able to reach a larger proportion of Appleton's population than one or two workers could hope to do.

"The representatives of the Appleton Woman's Club, the City Nurses, the Principal of the Senior High School and Vocational School assisted materially in the campaign.

"This working group in turn enlisted the cooperation of the Appleton members of the County Medical Society, and twenty-six physicians carried on the examinations.

"A committee of four from the County Medical Society organized the members into eight teams of three members each—two members acting as substitutes to fill in when other members could not be present. One member of each team was appointed captain and he was held responsible for his team—all incidentals pertaining to such a campaign, such as talks before the Senior High School and Vocational School, purchasing of supplies, arranging of the schedule for examinations, were handled by the committee.

"The schedule arranged for each team to work for two hours a day. Thus four teams worked from 8 A. M. to 5 P. M. The following day the next four teams.

(*Continued from page 990—Adv. xx*)

"1. To broaden the scope of the Journal so as to include in more prominent position the hospital activities of the State, having in mind that the alignment of physicians and hospital was becoming a more nearly identical one in facing the joint problems of the future.

"2. To secure, if possible, increased advertising revenue on the basis of the Journal being the publication medium of the Wisconsin Hospital Association. At the present time the Journal is not quite self-supporting. Because of high standards we are limited in securing additional copy from pharmaceutical houses. If the Journal were the medium of the Hospital Association I think we could secure some advertising of hospital supply houses, which copy is rarely secured at present"

Mr. Crownhart makes the following statements:

"In the interest of a clear understanding I wish to state here:

"1. Assuming that you continue your present compensation of the Secretary, such compensation will be to the State Medical Society and not to myself.

"2. The term would be not to exceed from year to year and at all times the Secretaryship may be summarily ended by your Board of Directors.

"3. Fully appreciative of the high personal compliment you convey to me in making the suggestion that I assume your Secretaryship, it is neither sought by this Society nor myself, but welcomed only as the future may prove it to be the means of joining in actuality what are already the joint interests of both organizations."

COOPERATIVE CLINICS BY ILLINOIS PHYSICIANS

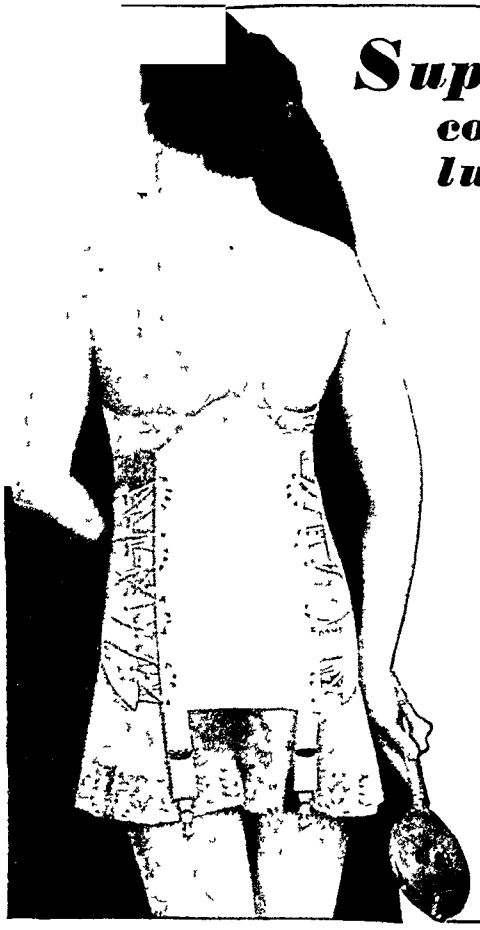
The voluntary establishment of what the author calls "Cooperative Clinics," is proposed by Dr. J. K. Narat of Chicago, in an article headed, "S.O.S. A Rush Call for the Creation of Cooperative Clinics," printed in the June issue of the *Illinois Medical Journal*. While the plan does not seem to have been adopted by any medical society, yet the seriousness of the proposal is indicated by the heading of the article in the Journal.

Dr. Narat first diagnoses four evils which affect the doctors, as follows:

(*Continued on page 992—Adv. xxii*)

(*Continued from page 991—adv. xxi*)

1. The general economic depression.
2. Medical centers organized and controlled by industrial concerns, insurance, health departments and philanthropic agencies. (These seem to be more potent in Illinois than in New York. *Editor's note.*)
3. Pay clinics conducted by teaching institutions and hospitals.
4. Self-medication fostered by the custom of physicians prescribing proprietary medicine which patients may buy.



The remedy proposed is that set forth as follows:

"The question has resolved itself into a virtual tug-of-war; the fight between such institutions and individual physicians resembles a fight between a giant and a pygmy; it is evident that the lilliput is fighting a losing battle. Here again the only hope to combat the usurpation of the practice by the pay clinics is to fight the antagonists with their own weapon, i.e., to establish rival cooperative, well-equipped and well-conducted clinics owned by physicians."

"The chief stumbling block in the path of emergency service for individual practice is the lack of joint activity. The gospel of cooperation and organization should be spread among the medical fraternity as rapidly and vigorously as possible."

"Groups create material and spiritual links, and promote good will and understanding among physicians. The success of the existing pay clinics in various parts of the country vividly illustrates the soundness of the system. The patient patronizing such a clinic benefits by receiving service of well trained physicians with large experience and having all the modern laboratory facilities at their disposal; the fees and also charges for drugs can be considerably reduced. The physician benefits by gaining experience, having opportunities for specialization and all the facilities for a complete scientific examination at his disposal; economic advantages in form of smaller overhead expense; possibility of taking a postgraduate course or vacation without financial losses, etc. The matter of economic security, however, while fundamental, is not half so vital to the physician as the appreciation of the fact that he is given the opportunity to work in a thoroughly scientific man-

"Pomeroy"
Supporting Corset

A good corset, properly made and fitted, not only gives needed support to the vital organs, but moulds the figure to correct and graceful lines.

The Pomeroy is ideal for this purpose, for it is so designed that the uplift is given by the corset itself with no need for additional belt or other contrivances. The intersecting laces give an extra upward and backward lift which further helps the muscles of the abdomen to give the necessary support.

ner and render services to his patients at a cost which is not a burden to the sufferer.

"As to the question of organization of such clinics, it is the writer's opinion that the local medical societies should be prevailed upon to arrange a popular referendum in order to elucidate the problem. Anticipating from the opinions gathered in numerous conversations with physicians the overwhelming majority probably will be in favor of pay clinics. If it shall be found in the open forum that it is a wish of a great number of physicians to create such clinics, it should be the duty of the medical societies or their respective branches to nominate committees invested with the duty to work out suitable plans."

"The medical society should insist that the clinics hold in high esteem the principles of ethics and do not succumb to enticement of ballyhoo advertising. If the majority of members are of the opinion that advertising is essential for the success of the clinics, a standard advertisement should be worked out which in a dignified manner would inform the public regarding the location and the scope of the clinic. Each clinic can advertise separately or preferably in a cooperative manner using for instance a slogan 'In case of sickness consult your nearest health center.'

"If for some reason or other the medical societies should be reticent to active participation in this plan, the only solution of the problem lies in organization of physicians without the aid of the local medical society."

There is an association of something over two hundred such groups in the Middle West, composed principally of specialists. The article seems to propose the formation of such groups by general practitioners.

This article is reproduced simply to inform the physicians of New York regarding what their Illinois brethren are thinking about.

SCIENTIFIC SERVICE COMMITTEE IN ILLINOIS

The July number of the *Illinois Medical Journal* contains the report of the Scientific Service Committee to the House of Delegates of the Illinois State Medical Society on May 5, which says:

"The purpose for which the Committee was created was to make available to county societies speakers on any subject that might interest the society. By being assured of their ability to secure speakers, it was hoped that many societies would be encouraged to meet more frequently.

(*Continued on page 995—Adv. xxv*)

(*Continued from page 994—Adv. xxiv*)

Efforts were made to encourage a study of those aspects of medicine which were apt to put the doctor in a bad light in the public eye, such as the infant and maternal rate.

"Lately an attempt is being made to encourage the study of mental hygiene. The treatment both preventive and curative of mild mental disorders is being stressed as being within the province of the private practitioner, particularly the family doctor. This matter is being studied by a group of our most distinguished neuropsychiatrists. They expect to evolve a plan whereby this subject can be presented to the rest of us in a simple non-technical language. The objection to having speakers on mental hygiene and the treatment of mild mental disorders before county societies has been their language has been too highly technical. We expect this group to overcome that objection. It is hoped that county societies will then take an added interest in this very important subject. Remember that about twenty per cent of the hospital space in this country is devoted to nervous and mental cases. Announcements of progress in this matter will be made through the office of Doctor Camp and the Educational Committee.

"The entire field of medicine has been divided into a number of specialties or otherwise and various groups of men particularly qualified in these fields have been asked to outline that particular field. Speakers have been asked to volunteer for service before county societies. The response has been generous in both cases.

"During the past year the Committee gave the following service:

"116 speakers were scheduled for scientific meetings.

"17 talks on surgical subjects.

"26 talks on medical subjects.

"8 talks on endocrinology.

"3 talks on gall bladder diseases.

"5 talks on gastro-intestinal conditions.

"7 talks on nervous and neurological conditions.

"3 talks on obstetrics and gynecology.

"6 talks on orthopedics.

"6 talks on genito-urinary and protologic subjects.

"10 talks on medical economics and medical organization (we even have one business man, Mr. W. K. Lasher, who is presenting the doctor's problem from the business man's point of view).

"3 talks on pediatrics.

"3 talks on dermatology.

"19 talks on miscellaneous subjects.

"34 counties were served and several requests for speakers came in from other States."

THERAPEUTIC ALMANAC

JULY

AUGUST

Summer diarrhea, cyclic vomiting in children, occur in keeping with the rise of the thermometer. Adults suffer, too. Changed diet, insufficient water intake, the hustle-bustle of vacations, strenuous sports and insufficient rest, all lead to *acidosis*.

℞ ALKA-ZANE

A teaspoonful in a glass of water, taken after effervescence has subsided, two or three times daily, (children in proportion) provides a refreshing, invigorating drink, and prevents acidosis.

Note—Alka-Zane combines the carbonates, phosphates and citrates of sodium, potassium, calcium and magnesium. No sulphates, tartrates or lactates; no sodium chloride.

ANNOUNCEMENT

The Post-Graduate Medical School and Hospital became on July 1 the Post-Graduate School of Medicine of Columbia University and will be controlled by an Administrative Board on which will be represented members of the governing body of the University, the Undergraduate Medical School, and the Post-Graduate School of Medicine. This Board will have general oversight and control of all post-graduate instruction in medicine offered by the University, whether at the Medical Center, the Post-Graduate Medical School or elsewhere in the city. Dr. Edward H. Hume will be the Director, and Dr. Alan R. Anderson, the Associate Director of the Post-Graduate School.

This incorporation of the New York Post-Graduate Medical School into the teaching system of Columbia University as its post-graduate school of medicine, distinct from the undergraduate school, carries into fruition, after some forty-nine years, the ambition of the seven founders of the Post-Graduate who resigned from the Faculty of the New York University upon the refusal of the Trustees to grant them a separate building for post-graduate instruction and, early in the year 1882, organized the present New York Post-Graduate Medical School and Hospital.

Dr. D. B. St. John Roosa, the leader of this small group of pioneers in graduate medical education, and first president of the institution he helped to found, in his inaugural address in November, 1882, pointed out that while temporarily undertaken in an independent institution, this type of medical education rightly belonged with other forms of professional instruction, within a university and closed with the forecast, "the time will come when this institution will be included within a great university." July first of this year will see this prophecy fulfilled.—See page xxxi—*Adv.*

VOL. 31, NO. 16 NEW YORK, N. Y AUGUST 15, 1931

TYPES AND LOCATIONS OF BRAIN TUMORS AND OTHER SPACE-DISPLACING MASSES WITHIN THE CRANIAL CAVITY OCCURRING WITHOUT "CHOKED DISK"

Report of Seventeen Cases

By DONALD L. BUTTERFIELD, M.D., ROCHESTER, N. Y.

From The Department of Surgery, Neurological Division, The University of Rochester, School of Medicine and Dentistry, Rochester, New York.

THE difficulties of diagnosis of brain tumor in a new neurosurgical clinic are not unlike those in general practice. Cases are seen early and at a time when complaints are difficult to interpret and may lead in any direction. Likewise characteristic physical signs may be lacking or sparse or difficult to interpret. Even more puzzling are the comatose or paralytic patients brought to the hospital with little or no history available. For this reason it may be helpful to present in some detail seventeen case records of space displacing brain lesions where "choked disk," the "sheet anchor" of the triad of headache, vomiting and "choked disk," was lacking. It may also serve to emphasize the need of keeping in mind the possibility of brain tumor or an equivalent mass even where that of a degenerative or vascular lesion seems a more enticing one.

The report of the occurrence of brain tumor or space displacing masses within the cranium without "choked disk" is of course not new. It has been going on spasmodically ever since vonGrafe[1] first demonstrated and described this phenomenon and associated it with intracranial lesions. Albutt[2], Jackson[3] and MacDonald[4] were early contributors to this fact. Beerman[5] in 1913 reported six cases. André Thomas[6] in 1921 reported that ten to twenty per cent of all tumors are not accompanied by "choked disk." Paton[7] places the figure at twenty per cent of 200 cases, Brain[8] at 21.6 among 60 cases, VanWagenen[9] at 16.5 per cent among 109 cases of cerebral and cerebellar tumors. All told, it is a hopeful sign that even this large a percentage of brain tumors is recognized before the development of choked disk and foretells a period when the acumen of the general practitioner will increase it still more.

The following seventeen case reports from the neurosurgical service of the Strong Memorial Hospital were observed over a period of approximately a year and a half. Fourteen of the seventeen cases represent brain tumors. The large cortical cyst of the parieto-occipital region was encountered which may have been present since birth. The other two cases—pacchymeningitis hemorrhagica interna—evidently of fairly long standing, are presented.

CASE REPORTS

Case 1. No. 32962. Ependymoma of fourth ventricle.

C. A., a 40-year-old woman referred by Dr. Boudreau of Syracuse, entered the hospital because of very severe attacks of pain in the left side of the face that closely simulated tic douloureux. Opiates relieved the pain but partially. Sleep was interrupted and inadequate. She also complained of diplopia, vertigo, nausea and vomiting. The first symptom was diplopia which came on some four months prior to entry. This was soon followed by symptoms of a left sixth nerve weakness and weakness of conjugate deviation to the left. Unsteadiness of gait soon followed and she was confined to bed most of the time.

Physical examination showed a woman who was rather emaciated from inability to take or retain food and lack of sleep. She was having frequent attacks of severe pain over the distribution of the right fifth nerve not exactly typical of trifacial neuralgia in onset, cessation, etc., but nevertheless very severe. There was a limitation of conjugate deviation of the eye movements to the left. Frequent examinations of the eye grounds showed them to be normal. A peripheral type of right facial weakness was also noted. Hypoaesthesia to pin prick over the right side of the face developed during the stay in the hospital as well as motor weakness of the right fifth nerve. Slight hypoaesthesia over the distribution

of cranial nerves nine and ten also developed. Deep reflexes over the left side became increased. Abdominal reflexes were absent. Laboratory studies and r-rays of the skull were within nor-

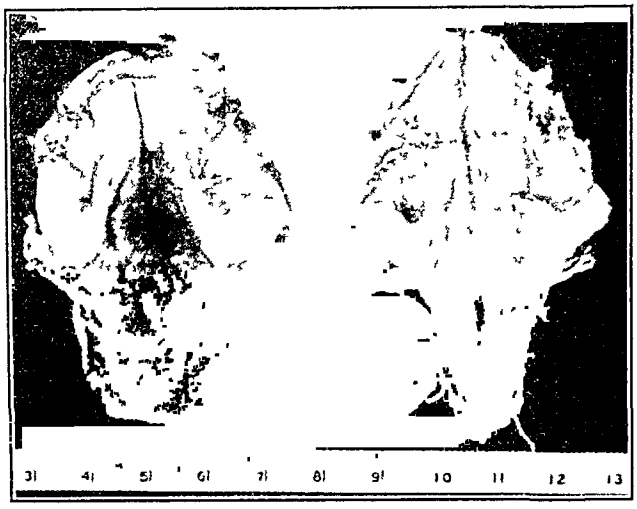

FIGURE 1

Case 1. Photograph showing extent of the bed of the tumor after the major portion had been surgically removed. It extended from the calamus scriptorius to the Sylvian aqueduct and from one side of the ventricle to the other.

mal limits. A diagnosis of tumor of the fourth ventricle and pons or multiple sclerosis was made The pain in the face became so severe that it was decided to section the posterior root of the fifth nerve through the extracerebellar route and at the same time, explore the region of the fourth ventricle. At operation, a tumor in the fourth ventricle was encountered. It extended from the region of the calamus scriptorius cephalad into the lower end of the Sylvian aqueduct and was everywhere broadly attached to the floor of the pons. Enough of the tumor was removed to free the opening of the Sylvian aqueduct. The patient succumbed some ten hours postoperative from hyperthermia and medullary edema.

Pathologically, the tumor proved to be an ependymoma. Fig. I and II.

Case 2. No. 28078. *Ependymoma of the fourth ventricle.*

E. B., a seven-year-old boy referred by Dr. John O'Connor, of Rochester entered because of weakness of the right arm, slight awkardness of gait, and general apathy for a period of some six weeks Mild fever was recorded from time to time during this period. An encephalitis lethargica was at first suspected.

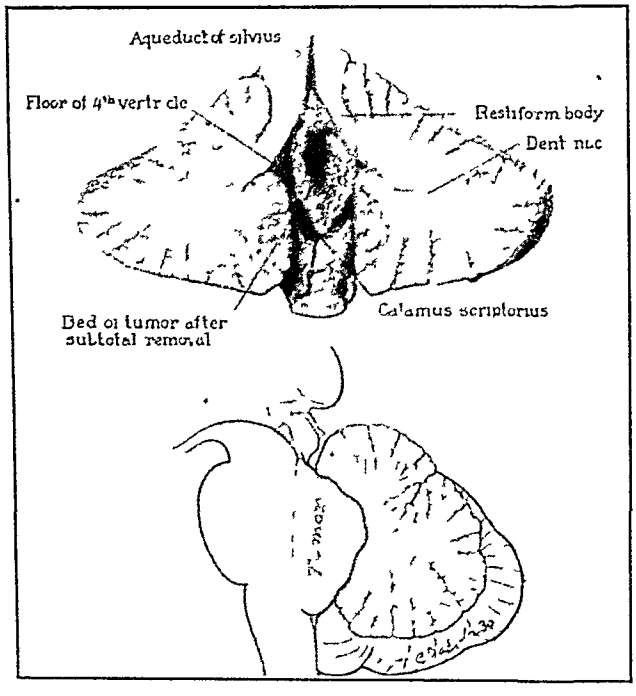

FIGURE 2

Case 1. Drawing showing the extent of the tumor and its relation to the fourth ventricle. Also a side view showing relationships.

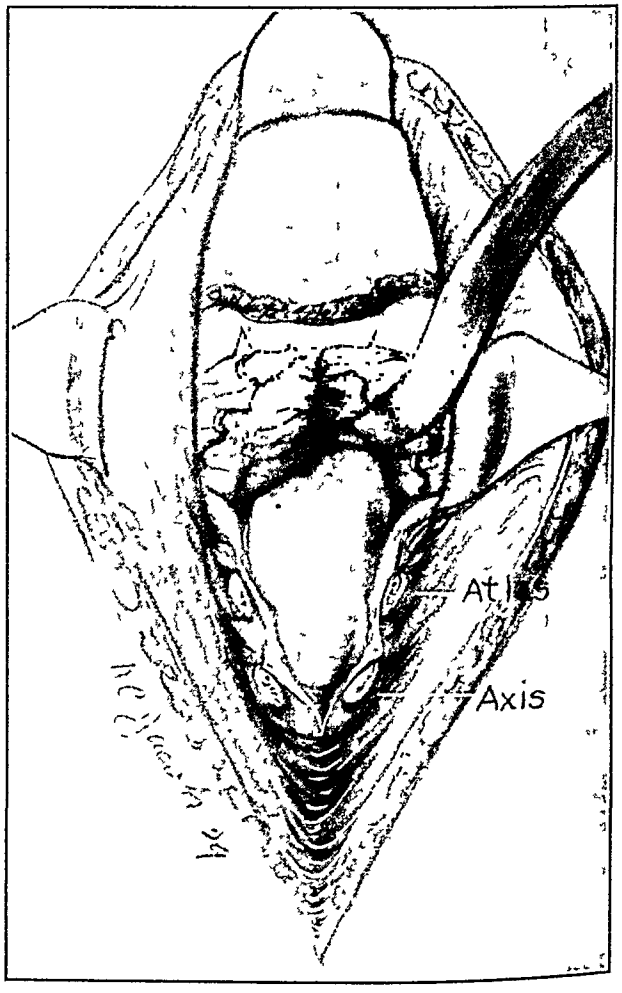

FIGURE 3

Case 2. Drawing showing the size and location of the tumor, an ependymoma of the fourth ventricle, its relation to the fourth ventricle and also the atlas and axis.

Physical examination showed little except hyperactive deep reflexes—possibly a little greater on the right than left. Babinski's sign was bilaterally positive as well as an ankle clonus. There was slight spasticity and ataxia of movements of the right arm and beginning atrophy of muscles of the thenar eminence of the right hand Romberg was at times positive Abdominal reflexes were absent. Vibratory sense was diminished below the clavicles though sense of position was normal. Sensation to pin prick and wool normal. The eye grounds were normal. Three attempts at lumbar puncture resulted in a "dry tap." A cisterna puncture and a lumbar puncture done under gas anesthesia showed a complete block below the level of the foramen magnum. Lipiodol injected into the cistern failed to leave in several hours.

A diagnosis of a tumor about the foramen magnum was made.

The cerebellum was exposed through a Cushing cross-bow incision and the arch of the atlas and axis removed after a tumor extending down into the foramen magnum was encountered. This tumor extended from about the level of the axis upward into the middle of the fourth ventricle It arose by a relatively small pedicle from about the left side of the calamus scriptorius and was easily removed at a second stage operation. Fig III. Pathologically it proved to be an ependymoma. The patient is entirely well to date, some ten months later.

Case 3. No. 19338. *Glioma invading the pons.*

R. P. a 50-year-old farmer, referred by Dr. Parker Murphy, of Rochester entered because of difficulty in speech and swallowing, numbness of the left arm as well as weakness and twitching of the muscles of that member. He also complained of moderately severe left frontal headache, and occasional attacks of vertigo and vomiting. The whole history dated back about a year. He had been able to work, however, until eight weeks before admission.

Physical examination showed a large man who had lost considerable weight presumably from inability to swallow food readily. There was obvious weakness of the right masticator group of muscles and the right pharyngeal and laryngeal group as well as the right trapezius and sternocleidomastoid. Slight weakness of the right seventh nerve was also noted. The eye grounds were normal. There was a left-sided hypoaesthesia to pin prick and wool, most marked over the left arm. Vibratory sense diminished over the left. Romberg positive. Deep reflexes were slightly increased over the left side but without ankle clonus or positive Babinski sign. Lumbar puncture failed to show any evidence of block and examination of the fluid was entirely within normal limits.

A diagnosis of a lesion involving the bulb was obvious but it was difficult to differentiate between a syringobulbia and a tumor of the floor of the fourth ventricle. The presence of headache suggested that he might have a hydrocephalus and for this reason a ventriculogram was done but the ventricles were of normal size and contour. In spite of this a diagnosis of a tumor of the fourth ventricle was hazarded and cerebellar exploration done through a Cushing cross-bow incision. A glioma of the pons was encountered. A portion of this tumor was taken for histological study and proved to be a glioma, type undetermined. Fig. IV.

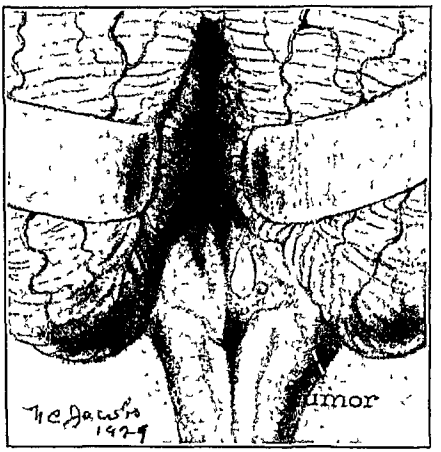

FIGURE 4

Case 3 Drawing made at operation showing the location of the tumor, a glioma of the pons, and its relation to the fourth ventricle.

Case 4. No. 21044. *Hemangioma of the pons extending into the fourth ventricle.*

H. B. a 36-year-old male referred by Dr. Eugene Boudreau, of Syracuse because of diplopia, staggering gait, deafness on the right side, weakness of the right arm and leg and thickness of speech.

The exact date of onset of present illness is difficult to determine. It probably extended back some ten or eleven years. At the time—1918—the patient complained of transient attacks of tinnitus in the right ear. This, however, disappeared in a few weeks and he was able to continue until about December, 1926. At that time, he had an attack of diplopia which lasted about one month. This was accompanied by a certain amount of vertigo and unsteadiness of gait, slight headache, and a feeling of general malaise. The above symptoms recurred in March, 1928, but were somewhat more marked. He was so un-

steady on his feet that he was confined to bed for a time. These symptoms cleared up in 2-3 months except for the diplopia which persisted at intervals up to the date of admission in January, 1929. The patient was able to work until November, 1928 as a die caster in a foundry. At this time, the diplopia, staggering gait and weakness of the right arm became so marked that he was finally discharged. Shortly after, he began to have thickness of speech, projectile vomiting on occasions, deafness in the right ear with ringing noise referred to that ear and an occasional attack of incontinence. Headaches became very marked during the last week or two prior to admission.

Physical examination showed a bilateral nystagmus, with a bilateral sixth nerve weakness more marked on the left side. The right pupil was larger than the left; there was a marked hypoaesthesia over the distribution of the right trigeminal nerve with a weakness of the jaw muscles on both sides. A right facial paralysis of the peripheral type was noted. There was a "nerve" deafness noted on the right side. A diagnosis of a tumor involving the pons and region of the fourth ventricle was made. Cerebellar exploration showed a marked bulging in the region of the inferior vermis. This portion of the cerebellum was split and a very vascular tumor encountered which bled profusely at the slightest touch. Evidence of bleeding from the tumor into the region of the fourth ventricle was apparent and some clots were removed from about the lower end of the tumor. A diagnosis of a hemangioma of the fourth ventricle was made, and the wound closed. The patient succumbed to medullary edema some forty-eight hours later. Autopsy revealed an extensive haziness of the pons which had invaded the floor of the fourth ventricle. Fig. V.

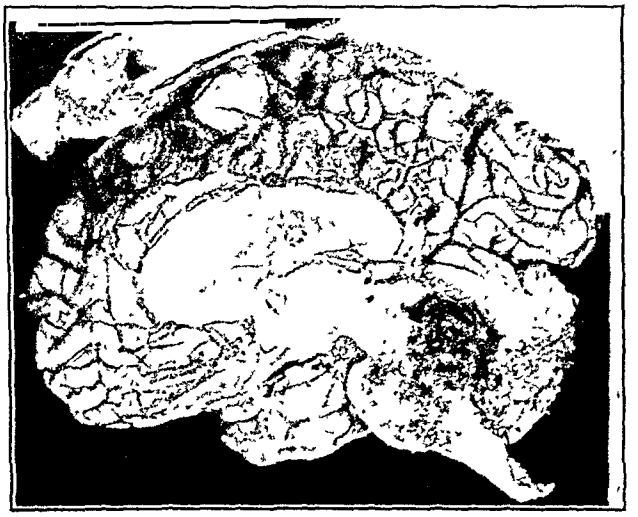

FIGURE 5

Case 4. Photograph of sagittal section of the brain showing the size and location of a hemangioma of the pons with extension into the fourth ventricle.

Case 5. No. 26746. *Metastatic tumor of the cerebellum—carcinoma of the lung.*

E. S. a 44-year-old woman referred by Dr. Charles Briggs of Fairport, entered because of headache, diplopia, staggering gait, deafness of the right ear and generalized weakness. The onset was relatively acute with difficulty in walking for three or four weeks prior to admission. She next became extremely dizzy on occasions and was confined to bed because of this. Vomiting attacks occasionally occurred. Diplopia had been present for about four days prior to admission. Headache had been fairly marked for three weeks prior to admission and was localized chiefly over the occiput.

Past history was essentially negative except for the complaint of general malaise and weakness for several months past. The patient was observed in the hospital over a period of three weeks. During this time symptoms became progressively worse. Emaciation due to inability to take or retain food continued to increase. Ataxia of both arms also developed as well as a bilateral mystagmus. A presumptive diagnosis of tumor of the cerebellum was made although the patient had no evidence of increased intracranial pressure. Consequently she was given deep *x*-ray therapy which seemed to aggravate existing symptoms.

Up to about this time the disks were well within normal limits, but began to show haziness about the border.

Physical examination in general was well within normal limits except for the emaciation. There were no obvious cranial palsies and no abnormal pyramidal tract signs. Otological examination showed a near deafness of the right ear.

A cerebellar exploration was done at which time a bulging and fullness in the region of the vermis was encountered. Vermis was split down the midline and a tough, fairly vascular tumor encountered about the size of a golf ball. The greater portion of this was enucleated. The patient made a fairly satisfactory postoperative recovery and was discharged some six weeks after operation.

Pathological examination of the tissue removed showed it to be carcinoma cells which were made up of columnar epithelium with a tendency to acinar formation. It was suggested that the gastrointestinal tract might be a source for this tumor metastases. Gastrointestinal *x*-rays however were negative. *X*-rays of the chest showed extensive involvement of both lungs, presumably due to carcinoma.

The patient died at home several weeks later. Autopsy was not obtained.

Case 6. No. 34303. *Left temporo-occipital glioma, ependymoma.*

A. C. a 50-year-old man referred by Dr. Benjamin Slater of Rochester, because of head-

ache, irritability, personality changes, lapses of memory and inability to use the right hand well. History dates back to a period about nine years ago. At that time he began to complain of numbness of the right hand which would last for a week to ten days at a time. This was occasionally accompanied by weakness of the arm and some weakness of the legs. The patient cleared up from this illness and was able to work most of the time until some three years ago when he developed diplopia and dizziness This persisted for a period of ten days and he was confined to a hospital for observation. Nothing in particular was made out and as his symptoms cleared he again returned to work. About three or four months prior to admission he again noted slight difficulty in bending and supinating the right hand. Shortly after this he experienced a blurring of vision which was not due to diplopia. About two weeks prior to admission marked changes in personality were noted, he became exceedingly untidy, irritable, seemed to walk about as though in a daze and suffered greatly from lapses of memory. It seemed to be impossible for him to remember details of work more than a few moments at a time. Weakness of the right arm and right leg soon incapacitated him for all work.

Physical examination showed a right homonymous hemianopsia, right sided weakness with increase in deep reflexes over that side including

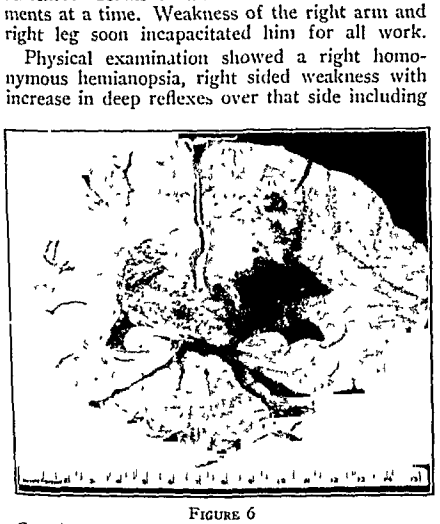

FIGURE 6

Case 6 Photograph showing the size and extent of the tumor, also its relation to the lateral ventricle. The measure is in centimeters.

an ankle clonus but no positive Babinski sign. There was a right-sided hypoaesthesia to pinprick, diminished superficial reflexes over the right side. There was a very definite apraxia and a bilateral astereognosis. Ophthalmic examination showed no evidence of choking of the disks. *X*-rays of the skull showed that the pineal gland was shifted toward the left side. It also showed an area of increased density to the left of the pineal gland and slightly above it. This was believed to be calcification in the tumor. At operation a large tumor was encountered in the left temporo-occipital region which was grossly invading the ventricle. A mass of tumor about the size of a hen's egg was removed before it became apparent that it was extending well across the midline and totally beyond the possibility of surgical removal. The patient died several days later; autopsy was obtained which showed involvement of the corpus callosum, thalamus, third ventricle with extension across the midline into the opposite ventricle. Histologically the tumor proved to be an ependymoma. The areas of increased density observed in the *x*-ray plates were verified to be due to calcification in the tumor. Figure VI.

Case 7. No. 36458. *Left subcortical glioma—fibrillary astrocytoma.*

E Z. a 41-year-old Russian woman referred by Dr. W. D. Ayer of Syracuse, was admitted because of Jacksonian attacks involving the right leg and to a lesser extent the right arm for a period of seven to eight weeks. At this time she began to notice twitchings about the right thigh muscles On one of these occasions she lost consciousness, had a generalized convulsion lasting 15-25 minutes followed by numbness of the right lower extremity. This was followed by six more attacks within the next few days

Physical examination showed a large, well developed woman having almost constant Jacksonian attacks involving the right leg and to a lesser extent the right arm. Two point discrimination was diminished over the right side. No differences in reflexes could be made out. At operation a burr hole was made over the left leg area and resistance encountered to the exploring brain needle. Consequently a bone flap was turned down in the postcentral region near the midline. There was seen to be elevation of the cortex above the surrounding brain surface. Palpation in this area revealed a hardness not encountered elsewhere. This was borne out by puncture with brain needle. It was thought at first that this was a metastatic tumor although *x*-rays of the chest taken with this in mind had previously proven negative The area was resected. Pathological examination showed the tumor to be a fibrillary type of astrocytoma.

This illustrates the possibility of the presence of a fairly large subcortical glioma without displacement of the pineal body to either side or without presence of headache, choked disks or vomiting.

Case 8. No. 20251. *Left temporal lobe glioma —unverified.*

F. B. a 56-year-old male who was referred by Dr. F. B. Collins of Webster, because of headache and personality changes such as refusal to eat, drowsiness and general apathy.

During the past year he grew irritable and uncooperative. During the last few weeks he had generalized headaches, and sometimes was confused and disoriented. He was somewhat drowsy, but could be aroused. A physical examination showed a left homonymous hemianopsia, nystagmus on deviation of the eyes to the right, weakness of the conjugate movement of the eyes to the left. Examination of the eye grounds showed them to be within normal limits. Within a few days, however, he developed haziness of the borders of the disk margins, the hemianopsia became much more pronounced, left sided weakness fairly marked and hypoaesthesia over the left side was noted. A right sided bone flap was turned down exposing the temporal lobe and the lower motor cortex. The brain was under increased tension. A surface or slightly subcortical tumor was not encountered. The ventricle on the right side seemed to be collapsed. Consequently a decompression was done and the wound closed. The patient has done extremely well under *x*-ray therapy and is back at work on a farm some one and a half years later.

Case 9. No. 34909. *Left postcentral glioma—histologically unverified.*

W. J. Y. a 49-year-old man referred by Dr. H. F. Knight of Rochester, because of a complaint of numbness and weakness of the right leg. The patient's complaints date back some four and a half months when the numbness and heaviness of the right leg were first noted. About two weeks later the same thing appeared in the arm giving him considerable difficulty in handling tools, etc. About a month after onset there was noted a tendency to a right sided toe drop.

On physical examination there was nothing of note except a slight weakness of all muscle groups of the right leg accompanied by an increase in deep reflexes over that side. There was also moderate loss of sense of position of the joints of the right lower extremity. *X*-ray examination showed what was interpreted as a pineal shadow displaced downward by a mass above it.

At operation a left sided bone flap was turned down exposing the upper motor cortex. The arachnoid over the leg area was very grey and thick, the brain beneath this seemed to be harder than normal and was exceedingly resistant to the exploring needle. There were so many large veins going across this area into the longitudinal sinus that it was felt inadvisable to divide them in order to explore the medial surface of the left hemisphere. A diagnosis of a glioma in the postcentral leg area seemed certain from inspection and palpation and material was not taken for histological study owing to the vascularity of the field. A decompression was done and the wound closed. He has been given heavy radiation with *x*-ray and radium apparently with good effect and is back at work some three months later.

Case 10. No. 1147. *Meningioma of the right lateral ventricle.*

A. L. C. a 47-year-old woman who was referred to the hospital by Dr. J. A. Cormier of Rochester, because of a complaint of drowsiness and vomiting over a period of two months. There was little else in the present illness or past history to warrant attention.

The only physical finding of note was that of a bilateral intention tremor brought out on effort. Reflexes were hyperactive throughout. On occasions there were noted nystagmus with a weakness component to the left and also varying estimations of normality of corneal reflexes on the right. The tongue at times deviated toward the left. On occasions the motor power of the right hand and arm was decreased compared with the left. Examination of eye grounds was entirely normal. Laboratory examinations throughout were generally negative. Examination of the skull showed a densely calcified mass occupying the region of the right ventricle and apparently representing a calcification in a tumor in the choroid plexus. Patient has been followed over a period of four years and is essentially well. No surgical intervention has been attempted. Figure VII.

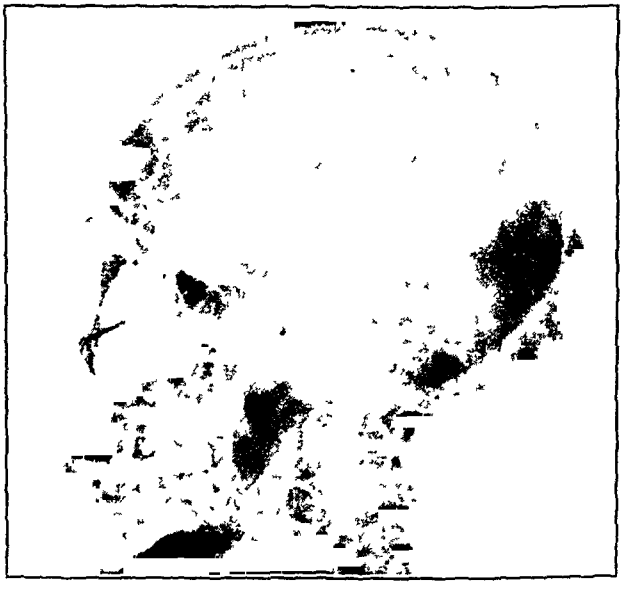

FIGURE 7

Case 10. Reproduction of x-ray film showing a densely calcified mass in the region of the right ventricle.

Case 11. No. 27690. *Cortical cyst of parieto-occipital region.*

R. S. aged 19 was admitted to the hospital complaining of "epilepsy." At the age of eight the patient had a series of seizures which occurred on an average of 1-3 times a day. Little could be found out regarding the exact nature of these early seizures, they have continued up to date with but few periods of freedom. A typical attack begins with a blurring of vision followed by loss of consciousness, overactivity of the muscles of the left side and oftentimes sensory changes over the left side. Many petit mal as well as grand mal attacks have occurred. On physical examination there was seen to be a well developed and nourished young woman with a few of the stigmata of chronic convulsive seizures. She was mentally retarded, suffered from rather poor memory and inability to reason or calculate rapidly. However she might have been able to do a considerable amount of work had it not been for the persistence of Jacksonian attacks. There was a left external squint, left homonymous hemianopsia, pallor of the nasal half of the left disk but no evidence of any elevation of the margins; left lower facial weakness on forced movements. A ventriculogram was done which showed a right sided hydrocephalus with enlargement of the ventricles posteriorly. The ventricles seemed to be displaced upward.

At operation a bone flap was turned down over the right parieto-occipital region. On opening the dura a large cortical cyst was encountered which contained about 250-300 cc. of brownish, chocolate colored fluid. Near the anterior end of this cyst was a definite hard, well marked out scar in the cortex of the post-central leg area. Both the cyst and scar were removed. Figure VIII. In so doing, the ventricle was opened and difficulty was experienced in the postoperative course in preventing a continued cerebrospinal fluid leak. It was only after removing the bone flap that this was accomplished. Patient has had a marked improvement in the number of attacks but is continuing to have an occasional seizure at the time of menstruation.

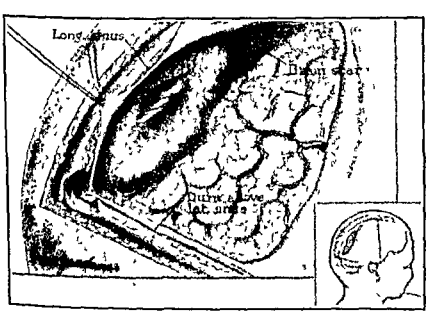

FIGURE 8

Drawing showing the size and extent of a cortical cyst adjoining the longitudinal and lateral sinuses. A brain scar anterior to the cyst extends into the post-central region.

Case 12. No. 18443. *Papilloma of left choroid plexus.*

J. S. an infant, aged three months, was admitted to the surgical service on September 3, 1928, because of bilateral internal squint and gradual enlargement of the head. The patient, a first child, was born at full term, weighing 8½ pounds (3.8 kg.). There was nothing of note in the birth record except slight difficulty in getting the patient to breathe following a normal delivery. Vomiting occurred several times at the age of five or six days, and hypodermoclyses of saline solution were given because of dehydration. At the age of 2½ months a left internal squint was noticed which cleared up in a day or so and then recurred shortly after, with an internal squint on the opposite side. This persisted up to the time of admission. About two weeks prior to entry the head was noted to be enlarging, the veins of the scalp to be more prominent, and the fontanels to be bulging more than usual. Vomiting had occurred only once in this two week period, and feedings had been taken about as usual.

Physical Examination: The patient was a well developed and well nourished active infant with a moderately enlarged head which measured 46 cm. in its greatest circumference and 30 cm. from the glabella to the external occipital protuberance. The fontanels were bulging moderately, and the veins of the scalp were fairly prominent. The only cranial nerve palsy noted was a bilateral abducens of moderate degree. The left arm and leg did not seem to be moved quite as much as the right though there was not any actual weakness noted. Deep reflexes on the left side were slightly increased over those on the right; neither observation was in keeping with subsequently disclosed conditions. On October 1, 1928, the right ventricle was tapped and clear fluid under increased tension escaped. Twenty cubic centimeters of a one per cent solution of indigo carmine was introduced into the ventricle, and the left ventricle was tapped a few moments later. On tapping the left ventricle, highly xanthochromic fluid, also under tension, escaped but no trace of the dye was encountered. A lumbar puncture done about a half hour later showed that a faint trace of the dye had reached the lumbar sac.

At operation under ether anesthesia a left sided bone flap was turned down. The surface of the brain showed much flattening of the convolutions especially in the temporal region. An incision was made in the postparietal region through the

thinned cortex extending into the distended ventricle. On the medial wall of the ventricle, about opposite the pineal gland region there was seen an irregular tumor mass 5-6 cm. in length and 4-5 cm. in height. The surface was grayish-red. Around this tumor was a delicate envelope which was rather closely adherent to it. The tumor appeared on inspection to be too vascular for biopsy. Consequently an opening about 1 cm. in diameter was made through the septum pellucidum to allow fluid to escape into the opposite ventricle. A small decompression in the left subtemporal region was made. The patient made an uneventful recovery from the operation and was discharged on the tenth postoperative day.

The patient received deep roentgen treatments on October 16, and November 6, 1928 and on January 15, 1929. There was moderate vomiting after each of these treatments. On February 6, 1929 the patient was readmitted because of the slowly increasing size of the head in spite of the roentgen treatment. Otherwise the patient had developed normally, and had gained steadily in weight and strength. The head measured 52 cm. in the greatest circumference, as compared with 46 cm. on the previous admission. There were no cranial nerve or pyramidal tract palsies. A right homonymous hemianopsia seemed certain from repeated examinations. The fontanels were under moderate tension.

Operation: On February 7, 1929 the left-sided craniotomy wound was reopened and the tumor exposed. There was at once apparent a striking change in its size and consistency. The tumor was firmer, appeared less vascular, and seemed to have decreased about 2 cm. in size in all dimensions. On dissection around the base it was found to be connected with the choroid plexus. Excision in toto was accomplished with the aid of the electrocautery. The patient made a good recovery from the operation, did not appear to have any pyramidal tract palsies and was again discharged on the tenth postoperative day.

Comment: The anterior portion of the choroid plexus was left intact though it probably would have been better to have put a silver clip on its blood supply or to have excised it entirely.

Pathological Examination: After hardening in a diluted solution of formaldehyde (ten percent) the tumor measured 4.5 by 3 cm. It was definitely limited on all sides by a thin delicate membrane of glial tissue. On cut section the granular papillary structure of the tumor could be made out. Numerous minute cysts were encountered. Two fairly large arteries could be seen going into the tumor at its base where it was connected with the choroid plexus. Histological examination of the tumor showed it to be a typical papilloma of the choroid plexus. Each section showed myriads of papillary projections most of which had a connective tissue core, as demonstrated by vanGieson's and Perdrau's stains. The papillae were covered for the most part by a single layer of cuboidal or columnar epithelium. Pseudostratification occurred in some areas. No cilia could be seen, and blepharoplasten could be demonstrated by either Hortega's silver carbonate or Bailey's ethyl violet orange G stain. Glia fibers in the stroma of the tumor could not be made out. The diagnosis was papilloma of the choroid plexus of the left lateral ventricle. Fig. IX.

FIGURE 9

Section of tumor—papilloma of choroid plexus—showing its size in centimeters and granular surface.

Clinical Course: Since discharge, now eight months ago, the patient has been relieved of the cerebrospinal fluid block. The head measures 49 cm. in its greatest circumference as compared with 53 cm. before the second operation and 46 cm. before the first. There are no pyramidal tract palsies. A partial right homonymous hemianopsia persists. Physical growth has continued normally. There has been in the last few weeks, however, a series of petit mal attacks. Mental growth has been much retarded.

Case 13. No. 17976. *Pachymeningitis hemorrhagica interna, left.*

E. M. This patient was brought into the hospital unconscious and without any history available. The pulse was 56 and respirations were 28 per minute. There was a fresh scalp wound over the left temporo-frontal region. Neurological examination showed a moderate degree of left sixth

nerve weakness, generalized rigidity and spasticity of all extremities with a positive Babinski sign on both sides, more marked on the left and bilateral ankle clonus. Examination of the eye grounds failed to show any variations from normal. Lumbar puncture showed spinal fluid to be under increased pressure—270 mm. water—and the fluid was definitely xanthochromic. A diagnosis of pachymeningitis hemorrhagica interna was postulated and a burr hole made over each parietal region. A large sac was encountered on the left side extending from the frontal region well toward the occiput and down over the temporal region. This was removed entirely leaving an enormous dead space which had to be filled with saline. Patient was much improved during the next 72 hours but gradually lapsed into a semicomatosed state. The wound was re-explored and an extradural clot evacuated. The patient then made an uneventful recovery following this Additional history furnishes the information that he sustained a hard blow over the left parietal region some 3-4 months prior to admission. This may have been an exciting factor in the etiology. The serology was negative throughout.

Case 14. No. 19010. *Hemangioma of left cerebral cortex.*

F. M. a 48-year-old man came to the hospital complaining of attacks of unconsciousness of five years' duration. During the year previous to admission, the attacks became more frequent and severe. They usually began as clonic spasm of the left foot which spread over the entire left side of the body and usually lasted about ten minutes during which he was unconscious. Following the attack he was usually quite confused and very tired for about one hour. The only other symptom was occasional mild headache.

On examination the patient was rather drowsy but was easily aroused and responded promptly Pupils were equal and regular and responded promptly to light and accommodation. Extraocular movements were normal. Ophthalmic examination showed only a slight blurring of the nasal margin of the disks. There was no "choking" noted. The cranial nerves were intact. General neurological examination revealed nothing abnormal.

A lumbar puncture showed the fluid to be under slightly increased pressure with normal rise and fall on jugular pressure. Stereoscopic x-rays of the skull were of no particular help. A ventriculogram showed dilatation of the left lateral ventricle. At operation a vascular tumor about 5 cm. in diameter was encountered in the right motor leg area which was adjacent to the longitudinal sinus and many vessels were seen going to and from the tumor. Because of the vascularity, no attempt was made to remove the tumor. Fig. X. The bone flap, however, was removed to expose the tumor more completely to x-ray radiation. Convalescence from operation was uneventful. He has had a fairly intense course of deep therapy. For one reason or another he has not had any further attacks. A few months after operation he began to lose weight and strength and re-entered the hospital for re-examination. Examination at that time showed weakness, emaciation and slow speech and other symptoms commonly ascribed to a low metabolism. A basal metabolic reading was —30. The patient was given thyroid extract 0.1 gm. t.i.d.

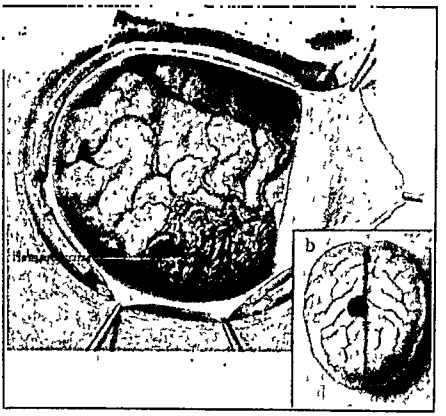

FIGURE 10
Hemangioma of cortex—leg area.

which he has taken intermittently without improvement for six months. When seen two years after operation, he has not had any more attacks but slight headaches have continued. Loss of weight and strength has persisted in spite of the treatment with thyroid extract.

Case 15. No. 40326. *Glioma of the right frontal lobe.*

C. M. a 40-year-old man referred by Dr. Norman Moore of Ithaca entered the hospital with the complaint of headache and fainting spells of seven weeks' duration. The fainting spells lasted approximately two minutes. This was followed by a severe headache over the vertex of the skull which radiated to the temporal regions lasting about two hours. At first these attacks occurred about every five days but became progressively more frequent and at the time of admission they were occurring three or four times daily. During the attacks there was some drooping of the left side of the mouth and rolling upward of the eyes. For four weeks previous to admission there was some roaring in the right ear and diminution in the sense of smell. For two days previous to admission, there had been nausea and vomiting. On the day before he came to the hospital, he noticed that he was unable to stand alone readily.

TRYPARSAMIDE IN THE TREATMENT OF NEUROSYPHILIS*

By H. C. SOLOMON, M.D., and S. H. EPSTEIN, M.D., BOSTON, MASS.

From the Boston Psychopathic Hospital, Boston, Mass.

TRYPARSAMIDE is a rather extraordinary drug in that it has a very definite beneficial effect on syphilis of the central nervous system, whereas it has very little spirochetal effect as measured by the results of treatment in cases of early syphilis. The manner in which its effect on neurosyphilis is accomplished has never been established. There are only two theories which have been advanced that are even sufficiently suggestive to merit discussion. The first is that the action of the drug is through a stimulation of metabolism. The basis for this statement is that patients often gain weight when the drug is given. No other evidence of change in metabolism has been produced, however, and the gain in weight is usually a transitory effect and not long-lasting, so that this hypothesis does not seem to be reasonably well established.

The other explanation of its effectiveness is that it penetrates the central nervous system more satisfactorily than do most other arsenical preparations. It has so very little spirocheticidal value, however, that even if it were able to penetrate to a much greater extent than is the case, there would not be a high expectancy for therapeutic benefit. It would therefore seem that at the present time we must be content with evaluating any results that may be obtained without being able to explain the mode of action.

In this paper we shall attempt to briefly outline our own conclusions as to the effect of this drug in early and late syphilis of the central nervous system, comparing it more or less to the effects of arsphenamin on the one hand, and fever therapy on the other. No attempt will be made to give detailed statistical tables. It is felt that such tables are very misleading as statistical material must vary so greatly, with such a high factor of change in the type of case that is treated. This is true, at any rate, as regards the cases of general paresis and tabes.

In our experience, the cases of early neurosyphilis of the meningeal variety, respond extremely well, practically without exception, in fact we have had no case of meningeal syphilis that has not responded extremely well to tryparsamide. This statement also holds for the ordinary type of early meningo-vascular neurosyphilis. Almost always clinical improvement will be noted in the course of three or four weeks. Serological cure is to be expected in these cases in the course of a few months, and as has already been indicated, a serological cure is, in our experience, inevitable.

This type of result relates to the central nervous system only, and not to the systemic infection, and it is in this respect that the great difference between arsphenamin and tryparsamide is made apparent. It is well recognized that there are many cases of syphilis treated from the primary stage which develop central nervous system syphilis despite the ordinary routine treatment with arsphenamin, mercury, bismuth, and iodides. Many of these cases develop both the symptoms and a positive spinal fluid serology during treatment which has been successful in clearing up the primary and secondary skin manifestations, and which has produced a negative Wassermann reaction in the blood.

A case of ours which has shown this interesting differentiation of the effect of arsphenamin and tryparsamide, is that of a man who presented himself for treatment during the late part of his primary period. Under conventional arsphenamin, bismuth, and mercurial treatment, his blood became negative and he was symptom-free. A year after the beginning of treatment he complained of severe headaches. A careful examination then revealed evidences of a syphilitic meningitis. The spinal fluid proved to be strongly positive in each test, with approximately 1000 cells per cmm. This syphilitic meningitis developed during conventional treatment and in the presence of a negative blood Wassermann. He was given weekly injections of tryparsamide unaided by any other drug. The symptoms promptly receded and at the end of a few months, the spinal fluid had become negative. While on this treatment, however, he had a relapse of blood Wassermann, which became positive, and about a year after the beginning of tryparsamide treatment he developed recurrent secondary skin and mucous membrane lesions, the latter containing many spirochetes. One injection of arsphenamin was followed by immediate improvement of the skin lesions, and after a short period of treatment with arsphenamin, the lesions all disappeared and the blood again became negative.

This case is particularly illuminating because of the development of central nervous system symptoms while under arsphenamin, the cure of these symptoms with tryparsamide, the development of skin manifestations while being treated with tryparsamide, and the disappearance once more of the skin lesions under arsphenamin. Much more frequently one sees the development of central nervous system symptoms while the patient is receiving ars-

phenamin with their involution following tryparsamide.

This sequence of events may occur in the late course of syphilis as well as in the early course. For example, a patient presented himself for treatment because of a positive blood Wassermann, and an old history of syphilis which began to concern him when his wife became pregnant. Examination at this time showed no clinical symptoms. The neurological examination was entirely negative, and the spinal fluid was in all respects normal. While on treatment consisting of arsphenamin, bismuth, and the iodides, the patient developed very definite mental and neurological symptoms of general paresis. Examination of the spinal fluid divulged a typically paretic formula. Under treatment with tryparsamide, the mental symptoms disappeared, patient returned to normal intellectual functioning, and the spinal fluid became entirely normal once more.

Similarly, in the late cases tryparsamide may have no effect on systemic symptoms, whereas arsphenamin is most effective. A woman diagnosed as a syphilitic epileptic with a positive spinal fluid, was treated for two years with tryparsamide and fever therapy. Just subsequent to the second series of malarial fevers, while receiving tryparsamide, she developed a tumor on the forehead. An X-ray picture was typical of a gumma involving the frontal bone. This occurred under our very eyes during a period in which there was clinical improvement as regards the convulsions and mental state of the patient, and with the spinal fluid which had become entirely normal. A few injections of arsphenamin was followed by improvement in the gumma as demonstrated both by the superficial tumor and the X-ray findings, and in the course of a few months of treatment with arsphenamin, the bone again appeared normal.

In late neurosyphilis of the more benign varieties, that is, in the cases of so-called cerebrospinal syphilis, or meningo-vascular neurosyphilis, predominantly of the meningeal type, tryparsamide is effective much as in the early cases, but there are undoubtedly exceptions to this rule. When one deals with late neurosyphilis, there is always a possibility of having pathological changes that are fixed and irreparable. Therefore, in a general discussion it is possibly well to consider the evidences derived from the serology. In many cases of the type mentioned, the spinal fluid will become negative with tryparsamide after a very few injections. There is no constancy or rule in this, however, and there are a fair proportion of the cases in which months of treatment are required for serological cure. In fact, we have one example of a patient with a typical clinical picture of meningo-vascular neurosyphilis whose spinal fluid was brought to normal only after six years of almost constant treatment.

At this point we would like to divert long enough to discuss the moot question of the relation of clinical and serological results. It has often been stated, especially in the discussion of the treatment of general paresis, that patients with serological improvement may show no clinical parallelism, and on the contrary, patients who make excellent clinical improvement may show no serological response. Without doubt, this is at times the truth, but our experience inclines us to the belief that in the first place the ideal is to have both clinical improvement and serological cure. In the second place, we are very strongly of the opinion that the cases which show clinical improvement without concomitant serological improvement, are quite likely to relapse. Finally, it is our opinion that the cases which show complete serological cure are likely to have a complete arrest of the activity and if clinical improvement has not occurred, it is because damage to functioning elements prevents improvement. A further point that we would strongly emphasize is the not infrequent serological relapse. As one follows cases under treatment with repeated spinal fluid examinations, one finds an occasional tendency for improvement to occur or even a normal fluid to be obtained, and then at a later period the fluid more strongly pathological in one or all of the tests. In our experience, when this occurs, it is only a question of time until a clinical relapse will also appear unless with continued treatment the spinal fluid has again returned to normal.

While on the subject of serology, one may further interrupt the course of the discussion to briefly mention the response to tryparsamide on the Wassermann reaction in the blood. Recognizing that tryparsamide has so little effect on systemic syphilis, one might conclude *a priori* that the blood Wassermann would not be greatly affected by tryparsamide. As a matter of fact, one frequently sees cases of neurosyphilis in which a long period of arsphenamin treatment has had no effect on the blood reactions, whereas, after a few injections of tryparsamide, the blood becomes negative and remains negative. Again, one sees cases which have had no previous arsphenamin treatment, in which the blood becomes negative after a very few injections of tryparsamide. On the other hand, in some cases, one, two, or three years or more of tryparsamide will be followed by a negative Wassermann reaction. Finally, there are still

other cases in which apparently a continuation of tryparsamide for a period of years will produce no change.

More crucial than the response of the simpler meningo-vascular type of neurosyphilis is the response to tryparsamide of cases of general paresis. Here the contrast between the effect of arsphenamin and tryparsamide is most striking. It is indeed exceptional for the spinal fluid serology to improve under arsphenamin treatment. On the contrary, it is the rule for improvement to take place when an adequate amount of tryparsamide is used. In fact, our experience has taught us that it is only the exceptional case of general paresis in which a definite improvement of the spinal fluid could not be obtained if tryparsamide is continued long enough. The time element is extremely important. Only in rare cases will the spinal fluid become negative in less than two years of continuous treatment, and in the majority of cases, at least three years is required, and in a great many cases five, six, seven, or more years are necessary.

We have been particularly impressed in studying the effects of tryparsamide on a group of rather chronic deteriorated cases of paresis. In two groups studied at two institutions, we have obtained almost invariable serological cure. These patients, markedly deteriorated mentally before treatment was begun, have remained unfit socially and require care in mental hospitals, but they have continued in good physical condition and the duration of life has been on the average more than five years, and, as mentioned, the serological result has been a normal spinal fluid.

It has been stated by many observers that clinical improvement with tryparsamide is usually obtained rather promptly, that is, within three or four months, and that if no clinical improvement occurs within this period, it is not likely to occur. In a general way, we are in accord with this statement. Improvement of clinical symptoms usually occurs rather promptly if it occurs at all. This, it seems to us, depends upon the fact that the inflammatory and irritative effects of the disease are fairly promptly improved, leaving what is the result of permanent nerve damage. On the other hand, relapses may occur either while the drug is being continuously used, or after it has been discontinued. As we have already mentioned, it is our opinion that the spinal fluid is a rather valid index of what is going to occur in this regard. Cases in which the spinal fluid does not show improvement at the end of a year or two of treatment, are likely to show mental relapse, and especially does it seem to follow that cases which have shown serological improvement and then a serological relapse, are almost certain to show a relapse in the clinical state in a short time.

In cases of this sort, we have had some rather satisfying experiences with the effect of fever therapy induced by malaria. The following case is a good example of clinical remission with preliminary serological improvement with subsequent serological relapse followed shortly by a clinical relapse, and then clinical and serological improvement after malaria.

A patient who showed signs of neurosyphilis with strongly positive serology and a depressed mental state in 1924, was put on tryparsamide therapy with clinical and serological improvement. After four years of treatment, during which time he received ninety-four injections of tryparsamide in doses of 3 gm. each, he presented the typical mental picture of paresis and the spinal fluid which had been improving again became strongly positive. After a course of therapeutic malaria, he immediately showed striking clinical improvement. About a year and a half later, the patient suffered another clinical relapse, and became profoundly depressed. Another course of febrile therapy was given, combined with tryparsamide. In a very short while the patient again improved clinically, and after a longer period of time the spinal fluid became practically negative.

This brings up the question of the comparative value of tryparsamide and fever therapy. This is a subject that we would very much like to avoid, largely because we do not feel able to give an adequate answer. To be sure, we do not believe that any adequate answer is available today. We will go so far as to say that we feel that by and large the results are fairly similar; that is, one may expect a thoroughly good clinical response in approximately 30 to 35% of the cases of general paresis treated by either method. As the above-described case indicates, a combination of the two methods is often much more satisfactory than either used alone.

Our routine is to give malaria, when possible, in cases of general paresis, following this invariably by tryparsamide until the serology has become normal and remains so for a period of several years. On the other hand, in the exigencies of our work, we find cases that we cannot hospitalize for malaria, or whose physical condition is such that we do not consider malaria advisable, in which case we treat them with tryparsamide. If the results are not satisfactory, then we give fever treatment.

One will find in the literature several state-

ments regarding the combination of fever and arsenicals. One statement frequently encountered is that cases that have had arsenical treatment, either arsphenamin or tryparsamide, do not do so well with fever treatment as the cases that are given fever without previous treatment. We have seen absolutely no evidence that this is the case. The history given above is an example, which we can repeat many times, of the beneficial effects of fever following tryparsamide.

A second statement is that it is dangerous to give arsenical products after malaria because of the effect upon the liver. As we have already mentioned, it is our invariable custom to follow malaria by tryparsamide, and as a rule we give two or three injections of arsphenamin immediately after the malarial fever in order to improve the anemia consequent on malaria, and because of its curative effect upon the malaria. In our experience of the past six years of this technique, we have seen no evidence of danger from this procedure.

Incidentally, another difference between the effects of arsphenamin and tryparsamide is seen in their effects on malaria. Arsphenamin will stop the inoculation malaria very promptly. Tryparsamide, on the other hand, has no obvious effect on the course of the disease and may be given simultaneously.

The effects of tryparsamide in the treatment of tabes dorsalis is not as easy to evaluate as it is in the other types of neurosyphilis. The results, on the whole, are good. In many cases, particularly when the symptoms are of quite recent origin, it is extremely striking. On the other hand, in late degenerative cases the clinical results are quite doubtful. It is in this group of cases that one not infrequently finds intolerance to the drug. The patient feels worse and loses weight and does not respond well.

As to the serological response, there is again a tremendous difference between cases. In some cases a very few injections of the drug will give a complete serological cure, whereas in other cases serological cure is obtained only after years of treatment. For example, a patient who had received his initial infection in 1912 had been treated for several years with arsphenamin and mercury. In 1920 he first noticed pains in his legs, and examination in 1921 showed signs of tabes with strongly positive serology. Arsphenamin treatment with spinal drainage was begun and continued until 1923. He was then started on tryparsamide which was continued for the next five years, during which time he received 137 injections of 3 gm. each. In spite of this treatment, the symptoms persisted, and the spinal fluid was changed but little.

We have not satisfied ourselves as to tryparsamide being more effective in tabes than is intraspinal therapy with the Swift-Ellis method. We do feel, however, that because of the much easier administration and less inconvenience to the patient, that it should be given in preference until it has been found to be relatively ineffective, in which case one would turn to another method, possibly the intraspinal. Likewise, we are unable to offer any conclusion in the comparative value of tryparsamide and malaria in the treatment of tabes. Again, our attitude is that tryparsamide should be tried first. As a matter of fact, we have used malaria very rarely in the cases of tabes, and generally in cases that have had an extremely rapid course. Here we have thought that considerable benefit accrued. We have also seen beneficial effects of malaria in cases of gastric crises which did not respond favorably to tryparsamide or intraspinal therapy. But here, the effect is probably not antispecific but more probaly due to change in the vasomotor and sympathetic systems.

There are some untoward effects to be met with in the use of tryparsamide, the most important of which is the occasional damage to the optic nerve. It has been stated that this is due to a reactive process in the interstitial tissue due to too rapid stimulation by the drug. Although we have no definite evidence to disprove this contention, we are still not satisfied with this explanation, and rather continue to accept the original hypothesis that it is an arsenic damage. However this may be, interference with vision occurs in about 3% of the cases treated. As a rule this is neither fargoing nor permanent. However, in an occasional case, very marked visual loss occurs. In one such case in which practically complete blindness occurred, Dr. Castner did prolonged and repeated spinal fluid drainage with very marked improvement of vision. In a few cases in which visual symptoms have occurred in our patients since that experience, we have used this method of spinal fluid drainage and there has been marked improvement in all such cases. Occasionally patients show dermatitis, although we have never seen a typical exfoliative dermatitis. Jaundice also is occasionally encountered but in none of our cases has this been serious. Rarely a patient shows intolerance to the drug as manifested by fever, sweating, nausea, vomiting, anorexia, and loss of weight. In our experience it is most likely to occur, as already noted, in rather advanced cases of tabes or patients whose spinal fluid is almost negative, or the rather burnt-out type. Finally, we occasionally meet with intolerance to the drug occurring after many months or several years of treatment.

GENERAL HOSPITAL NEURO-PSYCHIATRY*

By G. KIRBY COLLIER, M.D., ROCHESTER, N. Y.

THE importance of the care of the mental and nervous patient is coming to be more and more of a problem which we must seriously consider. The state has, through its munificence gradually assumed the care of the mentally ill until today there are in New York State sixteen hospitals for the care of mental diseases, provided by the State government at the enormous cost of sixty-five million dollars, in addition to twenty-nine private licensed institutions and four hospitals now under process of construction by the State. The State Hospitals, according to the last report of the Commission of Mental Hygiene, had a population of forty-seven thousand and the private licensed institutions were caring for twenty-six hundred patients. The State, through legislative appropriations and Bond issues, has been endeavoring to keep pace with the annual increase in the demand for their facilities, this annual increase being now around the two thousand mark, and we have no reason to doubt but that this increase will become greater as time goes on unless every member of the medical profession takes an active interest in the work of prevention or Mental Hygiene.

Dr. William A. White, in his inaugural address as President of the First International Congress on Mental Hygiene, recently held in Washington, stated, "Today, if we believe the statistician, there are walking the streets of our lands, five million young people who sometime in their life, will suffer from some form of mental illness."

In a study made by the late Dr. Thomas W. Salmon, he found that in a given year, one out of every twenty-two of the deaths reported to the New York State Health Department, occurred in hospitals for mental patients, and he concluded from his data, that about one out of every ten or eleven persons, became mentally ill in the course of a generation.

In a more recent study by Dr. Pollock of the New York State Mental Hygiene Commission, he shows a recovery rate o 20% in first admissions.

With these amazing figures before us, we should consider mental disease, not as an isolated problem to be cared for only in special hospitals for mental diseases, but as medical men viewing the broad problem of health from its every angle; we should consider as to whether our general hospitals are doing their duty in the care of this group of so-called psychiatric cases.

Our general hospitals occupy an important place in the preventive health activities of their respective communities. With the extension of the practice of medicine, the hospitals relationship to the communities are constantly widening and their services are ever being broadened to include all classes of the community. Health activities radiate from these hospitals, aiming at the prevention of disease and the promotion of personal as well as public health.

The general hospital of today, is, in a large measure, an educational institution, and it is gradually broadening this field.

Every patient and every hospital visitor, should and does receive some health educational stimulus from his or her contact with the general hospital of today.

We are all familiar with what has been done by organized medicine in the recognition, control and early care of the contageous diseases—tuberculosis, syphilis, etc. What has been accomplished by medicine in the last decade, reads almost like fiction, and we must and will expect an even greater productiveness in preventive medicine in the future.

With the growing recognition of the importance of early diagnosis and treatment of mental diseases, the modern general hospital is today being asked to give the nervous and mental patient the same chance to get well, as is afforded the physically ill patient: to repeat, when we consider that in New York State alone there are about fifty thousand patients cared for in hospitals for mental diseases, it is time that more consideration be given toward an earlier recognition of this class of patient and every aid at our command used in his care and treatment.

With the knowledge of the situation as it exists; are our general hospitals doing their duty toward this so-called group of psychiatric cases?

There is a common agreement among physicians and psychiatrists, who treat patients suffering from the milder mental and nervous disorders, that the existing modern general hospital, by adding a psychiatric department, would be able to offer effective care to many of this large group of patients.

It may be said, that the treatment and care which the nervous and mental patient requires is the same as that required by the average run of patients of general hospitals. All the diagnostic and treatment facilities, both in the matter of personnelle and equipment which are already a part of the general hospital, could be utilized in the interest of the mental patient.

Unfortunately, the lay public has not as yet adjusted itself to the fact that mental disease is in no way different than a physical disorder and that the mental patient requires equally as early and as good care, and as careful and as intensive study, as does that member of the family showing evidence of a physical disorder. He or she is entitled to the benefit of every diagnostic

* Read at the Annual Meeting of the Medical Society of the State of New York, at Rochester, N. Y., June 3, 1930.

method at our command but how often do we find that patient who shows early mental trends of a pathological nature, being kept at home, "under cover" so to speak, with the attitude on the part of the family, that it is a disgrace to have such a disease condition in the family.

The general practitioner or family physician is the first to meet this problem, and today his only place for care and treatment is in the home, where oftentimes, factors exist which are responsible for the lighting up of the disease or aggravating it, or else in a State Hospital.

That early borderland problem but seldom will accept State Hospital care and treatment even for short periods, but is quite willing to go to a general hospital for study. The general hospital is free of the prejudices which surround the mental hospital and we, as physicians, must rid ourselves of this prejudice first and the public will follow.

When it becomes known that patients with early mental symptoms would be treated in a general hospital having psychiatric facilities in the same way as other hospital patients, nervous and mental patients will be quite willing to go to the general hospital for study and treatment, at the stage when considerable help could be had, although they are most often unwilling to enter voluntarily, a mental hospital, even for temporary treatment.

The importance of the early diagnosis and treatment of mental diseases is being recognized more and more, and the question arises again; is the general hospital doing its part in the care of this group of the sick?

Under proper care and treatment in the psychiatric section of a general hospital, many cases would make a good adjustment or recovery and be restored to their family and friends without the so-called stigma of being committed to a mental hospital. The realization that through the psychiatric department of the local general hospital, adequate facilities for psychiatric treatment are available, means that the early treatment and care of mental diseases would be encouraged and effective steps taken in the prevention of the more serious forms of mental disease.

The type of nervous and mental patient to be reached by the general hospital, would include that growing number of persons whom we designate as nervous, exhibiting vague mental symptoms, or anomalies of conduct and of feeling, or some specific problem of behavior in children, persons whose nervousness is not severe enough to be regarded as illness, but whose condition renders it difficult for them to carry out life's normal activities and to assume life's responsibilities. It would take in those who are seeking help in the troubles which are common to everyone, fatigue, worry, jealousy, feelings of inferiority and insecurity, and mood changes. It would include the over-conscientious, as well as those who expect justice in the world, or those who meet the responsibility of the grown-up in a childish fashion, in other words, it would meet the needs of that mal-adjusted individual. By this recognition of the mental aspect of disease, the general hospital would be rounding out the services it offers to the community in combating disease and preserving health and would thereby take a more important place in the community's activities for the prevention and treatment of mental disease. The community would be saved the considerable expense that would be involved in the establishment and maintenance of a separate psychiatric clinic, since the hospital already has the medical staff and the diagnostic and treatment facilities needed for the modern care of mental patients.

The house officers, and the other members of the staff would become interested in the psychiatric case and their outlook broadened regarding the psychopathic personality, and the resultant transfers would be lessened. There would soon grow a new attitude toward the mental patient and a greater consideration of the individual rather than any disease process, and when you find a hospital, where the individual is considered, there you will find a complete hospital.

At the last meeting of the State Society, Heldt of Detroit, read a very interesting paper showing the comparative ease of care of the mental case in the Henry Ford Hospital. There a separate ward is provided for the psychiatric service, but in some of our general hospitals, beds are provided in the medical and surgical services for these cases.

In a recent statement made by Mathers of the Manitoba Canada General Hospital, where a ward of 32 beds is provided, he states that 65% of their admissions are returned to society.

In conclusion, permit me to stress:—

1. The importance of a more active interest on the part of the medical profession in the field of psychiatry, and mental hygiene.
2. The importance of the early recognition and care of mental disease.
3. The fulfillment of the general hospitals objective in caring for the sick of the community inclusive of all illness, whether physical or mental.
4. The comparative ease of care of the mentally ill in the general hospital in contradistinction to the generally accepted idea that he is a disturbing factor.

THE SIGNS AND SYMPTOMS OF MULTIPLE SCLEROSIS WITH PARTICULAR REFERENCE TO EARLY MANIFESTATIONS*

By ALBERT G. ODELL, M.D., CLIFTON SPRINGS, N. Y.

SO many of the statistical reviews of multiple sclerosis are based on the histories of patients treated in special hospitals for nervous conditions that it occurred to the writer to prepare a review based on the cases appearing over a term of years in a clinic of a general type such as Clifton Springs. As the study progressed there appeared some rather unusual facts which are noted in the body of the paper.

In this day, when more careful diagnostic studies are being made, many cases formerly diagnosed as sciatica are now known to be some form of spinal cord condition. Multiple sclerosis appears more frequently than in earlier years. This is undoubtedly due to the fact that we no longer wait for the Charcot triad before making a diagnosis.

A chart of the symptoms and signs in 48 patients is shown giving the number of those in whom the condition appeared and its percentage of frequency as well.

CHART A.

	Frequency	Per Cent of Frequency
Pallor of Discs	32	66.66
Absent Abdominal Reflex	31	64.58
Babinski	31	64.58
" (Questionable 2)		
Increased Knee Jerk	30	62.50
Nystagmus	25	52.08
Difficulty in Walking	24	50.00
Spasticity Present	23	47.91
Ankle Clonus	20	41.66
Speech	14	29.15
Slow or hesitant 8-16.66%		
Scanning 6-12.50%		
Bladder Irritability	13	27.08
Rhomberg	12	25.00
Ataxic or Spastic Gait	12	25.00
Loss of Vibration Sense	10	20.83
Intention Tremor	9	18.75
Loss of Position Sense	9	18.75
Numbness	7	14.58
Lessened Temperature Sense	6	12.50
Incoordination	6	12.50
Lessened Pain Sense	5	10.41
Lessened Passive Motion	3	6.25
Foot Drop	3	6.25
Oppenheim Reflex	3	6.25
Lessened Light Touch	2	4.16
Loss of Control of Bowels	2	4.16
Muscle Twitching	2	4.16

In our series about one-half of the cases gave as the initial complaint some disturbance in walking. This varied in degree from inability to lift the feet appreciably and resulting in a marked shuffling gait to slight difficulty as shown by tripping over obstacles or inequalities in the walks or pavements. In nearly all these cases there had been a gradual increase in the degree of the disturbance. It could not be ascertained from the history as to whether this involved one or both legs. The next most frequent complaint was a feeling of numbness or stiffness in the legs. With the average patient it seemed to be difficult for them to distinguish clearly between these two. It will be seen from the table that the difficulty in walking and spasticity are not so frequent findings as are other symptoms. This may be due to the fact that most patients do not apply for treatment until the process has become sufficiently advanced as to interfere with their comfort or ability to work.

For a long time, we have been accustomed to think of the Charcot triad of symptoms (intention tremor, scanning speech and nystagmus) as necessary to a diagnosis of insular sclerosis. Yet, in our patients these symptoms are well down in the list. Nystagmus is in fifth place being preceded by pallor of the discs (usually the temporal half being involved), absent abdominal reflex, the presence of a Babinski reflex, and increased knee jerks. Scanning speech appears well down in the list and intention tremor appears still more rarely. Lest it be said that there might be some question as to the diagnosis in cases used in the tabulation, there should be kept in mind the fact that only those cases were used in which no doubt of the diagnosis could be raised. For this reason ten cases diagnosed in the records as insular sclerosis were discarded.

A tabulation of the age and sex incidence is also interesting. In considering the age, it should be remembered that the age given is the age at which the patient came under treatment and not the age of the appearance of the initial symptoms. The latter is most difficult to obtain with any degree of accuracy but it may be assumed that the average patient had the symptoms for a period of one to three years before coming under observation.

CHART B.

Age	*Female*	*Male*
15-20	1	
20-30	5	
30-40	9	8
40-50	9	3
50-60	4	4
60-70	2	
70 +		1
Total	30	16

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 3, 1931.

In two cases, both females, the age was not given. This makes the incidence in 48 cases, 32 females and 16 miles or a 2 to 1 proportion in favor of the former. The age of greatest incidence is the same in both. The period between 30 and 50 years shows 18 women and 11 men. Put in the terms of percent, of the women 60% and the men 68¾% occurred in those two decades. The period from 30 to 60 years contains practically all the men and 73⅓% of the women. Why the women should be predominantly afflicted by this condition is a hard question to answer and one that will not be attempted in this paper.

Foci of infection have often been blamed for the occurrence of this condition. Yet a study of the records of these 48 cases, show that tonsillar infection is noted in ten patients only while carious teeth and peridental infection is spoken of in nine.

There were abnormal changes in the blood pressure recorded in six patients. Of these four were 105 systolic or below while two showed an increase to 170 systolic or above. Twelve patients had a secondary anemia and one a count suggestive of pernicious anemia but in whom that diagnosis was not confirmed.

Spinal fluid examinations were recorded in six cases. The sugar in two was noted as 0.056 and 0.073. Cell counts were recorded in five as follows: 42-15-14-10-6.

The physical condition of practically all the patients except as noted in the tables and the paragraphs following was very satisfactory, *i.e.*, no gross chest or abdominal pathology was found in any of the cases. In fact, most of them except for the neurological findings seemed in very good health.

For the purpose of a study of the frequency of this diagnosis among the patients admitted, the total number of diagnosis made, as well as those especially limited to the nervous system and finally the cases of multiple sclerosis from June 1, 1922, to May 31, 1930, are here set forth.

CHART C.

Years	Total number patients	Total diagnosis all diseases	Total diagnosis nervous system	Multiple sclerosis
1922-1923	3430	6074	791	8
1923-1924	3648	6687	1013	4
1924-1925	3870	7720	881	3
1925-1926	4250	10854	1023	4
1926-1927	4679	12247	1002	2
1927-1928	4602	12990	1119	5
1928-1929	4738	10169	1153	11
1929-1930	4469	10240	1139	10
Totals	33686	76981	8121	47

These show that a diagnosis of multiple sclerosis was made 47 times. During this same time there was a total of 76981 diagnoses of various sorts making the proportion of multiple sclerosis 1-1638 or 0.006%. Of the 76981 diagnoses made 8121 were neurological ones. They include all forms, organic, functional, etc. The proportion is 1-173 or 0.58%. In this period, 33686 patients were admitted to the clinic for study. Forty-seven of these were diagnosed insular sclerosis, making the proportion 1-717, or 0.14%. This means that with this proportion each year out of every 717 patients admitted, at least one will be suffering from multiple sclerosis.

Brain, in his monograph on this subject in the *Quarterly Journal of Medicine* (April, 1930) says that of 33090 admissions to the London Hospital in the years 1924-28, 116 or 0.35% were diagnosed as insular sclerosis. This is a much larger incidence than is shown among our 33686 admissions. However, there is abundant evidence showing that the incidence is much lower in the United States than in England and Wales. Brain believed that the occurrence in the general population is not over 0.005% in the United States as compared with an estimate of 0.016% in Great Britain. This would make the incidence in the United States about ⅓ that of England and Wales. Our group shows about ¼ the number of cases in approximately the same number of patients. He finds in the literature a marked divergence from our findings as regards males and females. In the literature as he reviewed it, the males predominate approximately 3-2. In our series the females predominate almost 2-1. Our general admissions from May 1, 1919 to April 30, 1930 show males 17637 and females 26633 or a ratio of 1½-1.

CHART D

	Ours	Birley & Dudgeon	Sachs & Friedman	Marquezy	Bohmig
Pallor of discs	1				
Absent abdominal reflex	2	3			2
Babinski reflex	3	1	2	1	
Increased knee jerks	4				
Nystagmus	5	4	3	4	3
Difficulty in walking	6			2	
Spasticity	7				

This chart shows the variability of the occurrence of symptoms and signs as recorded by various observers when compared with their order of frequency here. These figures are quoted from Brain. Note the wide variation of early and frequent symptoms as recorded by the men whom he quotes. It would seem that if one waits to make a diagnosis until the Charcot triad (nystagmus, intention tremor and scanning speech) are present, the patient will be well along in the disease.

Brain's statement is to the effect that this triad occurs in 10-12% of cases only.

It will be noticed that no attempt has been made to discuss etiology, treatment, or differential diagnosis. The writer wishes, however, to emphasize one point and that is the necessity of the use of lumbar puncture, lipiodal, and *x*-ray before making a positive diagnosis of insular sclerosis. This point is forcibly brought out by Ayer in a paper given last year and by Palfrey in its discussion. (Symptoms and signs of Tumors involving the Spinal Cord, *N. E. Jour. Med.*, 203, 295, 1930).

Summary: Our studies seem to indicate that when any patient complains of vague difficulty with the legs, especially in walking, a thorough neurological examination is in order and that this should include an *x*-ray study of the spine after the intra-thecal injection of lipiodal to rule out the presence of a cord tumor. It also confirms the findings of others to the effect that among the earlier signs of insular sclerosis will be found difficulty in walking, temporal pallor of optic discs, absent abdominal reflex, hyperactive knee jerks, and nystagmus.

As a rule, if scanning speech and intention tremor do appear in the picture, they will be late symptoms and their appearance should not be awaited, if one wishes to make an early diagnosis of multiple sclerosis.

HEATING APPARATUS FOR INTRAVENOUS SOLUTIONS

By HAROLD F. MORRISON, M.D., TUXEDO PARK, N. Y.

The described method has been used at the Tuxedo Memorial Hospital for maintaining the temperature of intravenous and subcutaneous medications. The apparatus consists of a narrow wooden box, containing two ordinary finger bulbs in the back, these furnish the heat. The front is open and in this opening is placed the graduated cylinder of the ordinary intravenous set.

Figure 1 shows the apparatus with one side removed to show the lights and cylinder in position.

In practice the heating box is hung on an irrigation stand and lights turned on. The intravenous set is filled with the solution which has previously been warmed and all air expelled from the tubing. The cylinder is then slipped into the front of the heating box.

At the ordinary rate of flow for intravenous medications the temperature in the cylinder is constant for all practical purposes.

The advantages are:

1. Cost: Inexpensive, the heating box can be made by any carpenter.
2. Simplicity: The usual intravenous set with cylinder container can be used without change.
3. Temperature: Constant.
4. Illumination: Because of lights behind the cylinder the rate of flow and amount given are easily read.

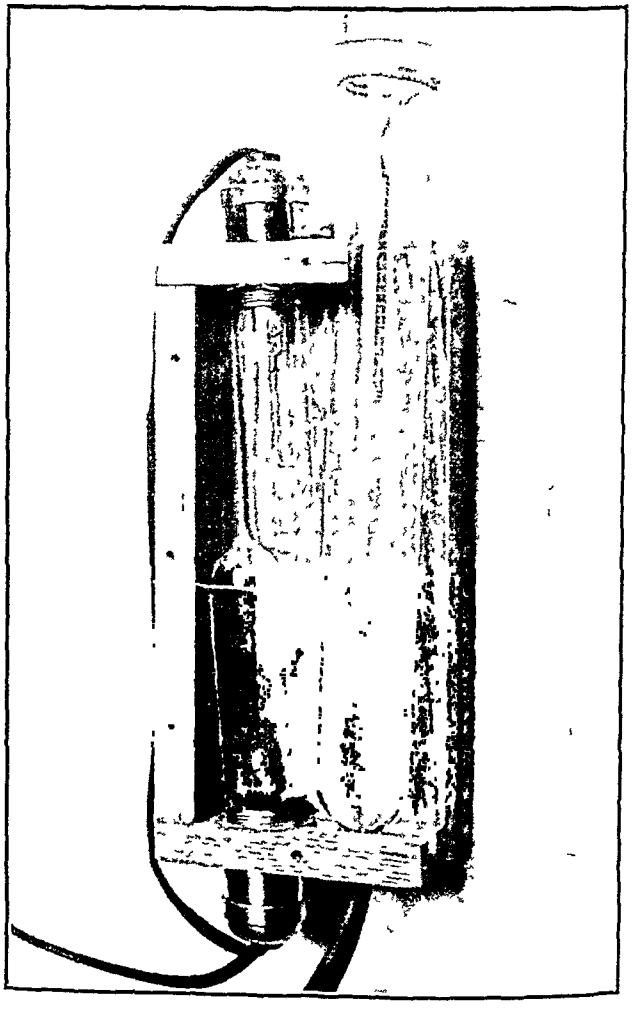

FIGURE 1

POSTOPERATIVE ILEUS, ITS EARLY RECOGNITION AND CONTROL*

By DONALD GUTHRIE, M.D., SAYRE, PENNSYLVANIA

MODERN preoperative preparation, the development of operating technique to the highest degree and the intelligent and watchful postoperative care of the patient requiring an abdominal operation have greatly lessened the mortality and the morbidity of abdominal operations of all types. Although occurring much less frequently than in former days, postoperative ileus—and by this term I include the two types, dynamic or mechanical and adynamic or non-mechanical—is still the cause of much of the present day mortality following abdominal surgery.

All measures which tend to prevent the occurrence of this serious complication are well worth consideration at all times and at any medical gathering; and even more important is a review of the early symptoms which makes it possible to recognize and control the condition early, for here the time factor is of greatest importance. Both types of ileus may be caused by prolonged operations, badly given anesthesia, rough handling of the patient's tissues and his viscera, great loss of heat, time and bodily fluids and the leaving behind of raw surfaces within the abdomen, although it must be remembered that mechanical ileus may follow the most trivial sort of an abdominal operation. The experienced surgeon can often tell just how smooth or stormy the postoperative course of a given patient may be by the amount of trauma necessary to employ at the time of the operation. All measures which promote gentle, intelligent, accurate, rapid work should be encouraged. The advantages of a well trained operating team and the skillful administration of the anesthetic are most important. A very important part of the young surgeon's training should be to develop in his mind, early in his work, a holy and sacred regard for the unconscious man's tissues, and it should not be beneath the dignity of any house surgeon to be given a retractor and taught how to handle it correctly. For this very reason I have never used or allowed to be used in my clinic any form of self-retaining retractor. Sharp dissection at all times should be carried out and rough gauze dissection discouraged.

Several years ago I described a method of Trendelenburg anesthesia. The sole object of the method is to prevent the use of gauze packing in pelvic surgery. Briefly, the anesthetic is begun with the patient in high Trendelenburg position. By the time the abdomen is opened, the pelvis will be practically free of all loose intestinal coils, so that it is often only necessary to use the end of a square of gauze in the upper angle of the wound in order to obtain adequate exposure. Naturally, one may expect a far less degree of postoperative reaction and a far less degree of meteorism or ileus in a patient operated upon by such technique, than one in whom it is necessary to use large quantities of gauze and much rough manipulation within the abdomen in order to obtain the necessary amount of exposure.

One of the advantages of spinal anesthesia in the carefully chosen case, is the complete relaxation of the abdominal wall and the collapsed state of the small intestine which permits complete exposure with the use of the smallest amount of gauze. Let me emphasize the importance of avoiding trauma within the abdomen, especially to the small intestine and particularly to the upper portion of the small intestine, for trauma here is not well borne and is one of the commonest causes of postoperative ileus.

The symptoms of postoperative adynamic ileus are not by any means cardinal and the condition is oftentimes hard to diagnose from mechanical ileus low down in the intestinal tube or beginning general peritonitis. The patient is apt to belong to the highly strung neurotic type who stands psychical and physical trauma badly—I remember a fatal case of gastro-mesenteric ileus, proved by autopsy, which followed the most trivial injury—there has been a certain unusual degree of operative trauma employed during the operation and there may have been a degree of postoperative shock. During the day following the operation the patient is restless, the expression is anxious, the pulse is fast, the abdomen is distended and silent and there is regurgitation of gastric and duodenal contents. Mild degrees of ileus are encountered, of course, which are self-limiting and disappear at the end of 24 to 36 hours after onset.

The treatment should be fluids in large quantities, sodium chloride and glucose—an inlaying nasal catheter, if well borne; if not, frequent gastric lavages through a Levine tube to keep the stomach free of gas and secretions; heat to the abdomen and psychical support to the highest degree. It is extremely harmful to frighten these patients during this critical time. The abdomen should be auscultated at frequent intervals, for the appearance of peristaltic sound is generally a harbinger of a prompt improvement. The rebellious case which does not improve is the one which de-

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 3, 1931.

mands our closest observation and prompt radical measures to control. As mentioned above, the condition is often hard to differentiate from early mechanical ileus developing near the ileocecal valve, or beginning general peritonitis—both such conditions may have an ileus plus the mechanical fault as well, and the abdomen is distressingly silent during this stage.

We have used the method suggested a year ago by Willard Bartlett to great advantage in our work. Bartlett recommends spinal anesthesia postoperatively, as the best means of differentiating between adynamic and dynamic ileus. The operating room is in readiness. The patient's family understand an operation may be necessary and have given their consent to it; the patient is given a spinal anesthetic and if the bowels do not move in the bed within fifteen minutes the patient is taken to the operating room and an enterostomy or a more radical operation is carried out while the patient is still under the spinal anesthetic. Should a mechanical lesion be present, the fallacy of not operating at once is easily understood, for the contraction of the intestine may hurry the intestinal contents up stream. I regard the use of pituitrin or purgation in these cases as extremely dangerous. We have employed Bartlett's method six times in our work within the past year. We obtained immediate bowel evacuations in four patients, two other patients were operated upon immediately for a mechanical fault. Before employing Bartlett's method, we used enterostomy to control these cases in all instances, the operation acting as a means of deflating the intestinal tube, but we still use enterostomy for the case which will not respond to spinal anesthesia.

I believe a greatly distended small intestine, at times, is unable to contract even though the inhibitory impulses are removed by the spinal anesthetic. A greatly distended intestinal tube is very much like a distended inner tube, oftentimes, which will form a mechanical obstructive point where it turns a corner and is kinked. Bartlett's method works beautifully in the early case before great distention has occurred, but enterostomy should be employed for the aggravated case of adynamic ileus.

We have six living patients upon whom it has been necessary to employ multiple enterostomies in order to save them; one is the wife of a physician—one is the daughter of a physician.

Dynamic ileus is easier to recognize than adynamic ileus. As a rule, an operation leaving raw surface in its wake has been performed, or some inflammatory lesion has been present. When the obstruction is high or at a point midway in the intestinal tube, there is early vomiting—not great distension, and the patient is seized with regular recurring cramp-like pain with periods of quiescence. Early in the attack, the patient can almost time the period of pain recurrence. Auscultation of the abdomen is the most important of all diagnostic methods to be employed, for one can elicit exaggerated peristaltic sounds and the recoil of trapped gas and fluids during the periods of pain. These sounds are most characteristic, and we should teach our younger men to interpret them. Intestinal patterns are also pathognomonic of dynamic ileus and they should be looked for in all suspected cases. Careful inspection of the patient's well bared abdomen is most important and the examiner should spend much time to inspect such an abdomen during the periods of quiescence and pain, even though this requires a long time.

Barium enemas or barium by mouth should not be given or relied upon to make the diagnosis. Barium by mouth is dangerous—by enema, it reveals nothing except that the obstruction may be in the big intestine, and the technique of administration causes delay and the loss of valuable time. One may, however, learn much by an x-ray plate; if the obstruction is in the small intestine, we will find a collapsed large intestine and the parallel coils of distended small intestine, showing the herring bone pattern or Kerkring's folds. Obstruction in the large intestine may be made out by x-ray and often the surgeon may plan his incision to cope with the obstruction, the site of which can be told by x-ray.

Recurring pain, vomiting, exaggerated peristaltic sounds with the presence of intestinal patterns are all the symptoms one needs to diagnose postoperative intestinal obstruction and the sooner these patients are operated upon, the better. This is no time or place for a hypodermic of morphine, until the diagnosis is firmly established and arrangements have been made for an operation; then, and then only should morphine be given. There are many writers who believe that morphine is responsible for more than half the deaths occurring in acute obstruction. It is only by repeated warnings that surgeons can educate the general practitioners to withhold morphine in all acute abdominal conditions, until the diagnosis has been made and the seriousness of the situation explained. It is regrettable, also, that so few abdominal conditions, which are purely medical, require morphine. Morphine disguises symptoms, interferes with a correct diagnosis and gives a sense of false and dangerous security in all acute abdominal surgical conditions.

Unfortunately, there is often much delay—the surgeon dreads to re-operate upon his patient—the family may sense his uncertain frame of mind and begin to lose confidence; the nurse reports the passage of gas with the last enema—false encouragement, for the gas passed is probably in the tube below the point of obstruction; more purgation may be resorted to—a murderous practice, for the purgatives, if retained in the stomach, hurry the trapped intestinal contents higher up in the intestinal tube. Finally, the patient develops great distension, the pulse is very fast, the skin leaky, the abdomen is silent, fatally so; there is vomiting of fecal matter—all signs of impending death.

It is regrettable that patients are admitted to our hospitals in such terminal stages of acute intestinal obstruction; it is far more regrettable, in fact, deplorable oftentimes, that the postoperative case is allowed to pass into such a stage in some hospitals, because the operating surgeon lacked the courage or the knowledge to cope with the symptoms of early postoperative mechanical obstruction.

There are two types of treatment, depending upon the promptness of the diagnosis, the amount of distention of the abdomen and the general condition of the patient, all of which will vary with the time the operation is decided upon.

If the original operation has not been performed for an infective or suppurative process and the obstruction occurs midway or high in the small gut, if the diagnosis is made promptly, if there is little distension and if the general condition of the patient is good, it may then be safe to re-open the incision and correct the mechanical fault. If there is great distention, and the patient's condition affected, enterostomy is by far the best procedure and will save life; if the original operation has been performed for an infective process, it is best not to disturb the infected field, but do an enterostomy. I cannot agree with those who advocate entero-anastomosis between greatly distended and collapsed coils. This operation is contrary to all the principles which govern intestinal anastomosis.

In operating originally upon a case in which there is widespread early infection, we do not hesitate to perform a complemental enterostomy. In this way an obstruction duplex, should it develop, is controlled early. We also have, not a few, but many cases of widespread peritonitis which, I am sure, would have died without thorough drainage of the intestine.

Unquestionably, surgeons in the past have been responsible for some of the high mortality in all types of intestinal obstruction, because, in their efforts to help the patient, their operations have been far too radical and the patient far too ill to withstand the operative attack. The simple operation of enterostomy has come into great favor and is a life-saving measure. I should be almost as loath to attempt abdominal surgery without it, as I would to do goiter surgery without the use of Lugol's solution, or treat diabetes, were I a clinician, without insulin—for properly performed—it saves many patients, which in former days were lost. It is not always possible and not always necessary to relieve the point of obstruction; as you well know, many points of obstruction relieve themselves after the distended coils are deflated. We have not few, but many patients recover by this simple measure, whom we would have lost had we been more radical. The method, described lately by Holden, of evisceration of every patient who has obstruction, with direct emptying of all the distended coils, I consider dangerous—for so many patients may be saved by simpler, safer and less radical methods. Should strangulation be present, the simple operation of enterostomy will not correct the pathology, but the life of a very ill patient with strangulation, may be saved by the simple operation of enterostomy done as a first stage procedure, preliminary to a later resection when the patient's condition will warrant such an operation. Let me urge you not to be too radical with these very ill patients and urge you to use enterostomy.

If we appreciate the effect of the toxin upon the chemistry of the body, it is important to give quantities of fluid with salt before operation. Time should always be taken out for this measure. Quantities of salt solution should be given before, during and after the operation. Fluids, fluids and NaCl—isotonic and hypertonic salt solution. Hughson has shown that hypertonic salt solution stimulates peristalsis and may be a factor in stimulating the distended and paralyzed bowel. The intake of salt may be rapidly increased by giving two per cent solution by hypodermoclysis and a three to five per cent solution intravenously.

The chemical processes of the body cannot function properly without a sufficient supply of water; therefore, in patients very ill with obstruction we give from five to six liters of water every twenty-four hours subcutaneously, intravenously and by rectum. We agree with Crile, who advises water early, water continuously and water late.

Earlier in this paper I took exception to Holden's radical advice of evisceration of all these patients, and with drainage of the contents of the obstructed loop. In analyzing Holden's article, I find many of his patients

were immediate postoperative ones occurring in his own hospital. I am sure the diagnosis was made early and there was no need for such radical procedures as he advocates.

The remarkable thing about enterostomy is the infrequency with which anything further is required. It is the rarest thing to be forced to re-operate and correct the obstructed lesions —they generally correct themselves. I am sure that those who have had much experience in this work will agree with this statement.

The operation of enterostomy is a simple procedure, but it is well to call attention to a few technical points which are very important and to emphasize the need of intelligent postoperative attention to the tube, to keep it draining and prevent the intestinal contents from being retained. In very ill patients the operation may be performed under local anesthesia; if the case is an early one and the condition of the patient good, we prefer to use ethylene.

A left rectus incision extends from the left costal arch, downward, for a distance of not more than 6 c.m., unless there is a large amount of subcutaneous fat, then a larger incision is used. The peritoneum is opened only for a sufficient distance to permit the exit of a single knuckle of distended small intestine. Should the omentum block the incision and be adherent in the pelvis so that it is impossible to catspaw it upward and out of the way, we do not hestitate to split the omentum through an avascular zone and allow a distended knuckle of gut to slide through the split into the incision. Let me strongly advise against a large incision which will favor the release of several distended coils of intestine through the incision.

In the control of mechanical obstruction, it is best to have the end of the rectal tube pointing downward in order to take advantage of the reverse peristaltic waves. The direction of the gut may be easily determined by Monks' method, by insinuating two fingers down along the mesentery of the gut to the root of the mesentery. When the mesentery is followed down with the fingers on the left side of the intestine the fingers must enter the left fossa and cannot get into the right fossa without first crossing over the intestine. On the other hand, if the right side of the mesentery is followed down to its root, the fingers can only go into the right fossa. One side of the mesentery leads to the left fossa only, and the other side to the right fossa.

The operation is performed between two intestinal clamps. After the upper one is locked, the gas in the distended coil is expressed downward into the gut by squeezing the coil between the fingers. When the knuckle is collapsed the lower clamp is closed. This is a very important technical point, for it is hazardous to place a purse string suture in a greatly distended thinned-out loop of small intestine. The first purse string suture is placed so that the center will easily admit a rectal tube of small size, clamped at its distal end. This tube not only has an open end, but a side opening is made one inch from the end. The gut is opened with a sharp-pointed knife in the center of the area included by the purse string and the small amount of bowel contents carefully caught in sponges; the tube is inserted—end pointing downstream and the purse string tightened and tied, and the ends tied about the tube; the ends of the suture are cut and a similar purse string is placed about the tube, tightened and tied—the ends are again tied about the tube. The clamps are now removed and the loop containing the tube is allowed to become distended with gas. If the loop has been brought up through a split in the omentum, the edges of the fold are brought together over the tube with a suture or two of catgut; if the loop has been free, a gentle attempt is made to find the omentum—lift up its free end into the incision, split it and draw the clamped end of the rectal tube through the split. This serves as an excellent protection to the suture line and safeguards the patient against the development of a fecal fistula. Even though it is impossible to use this omentum as a protective pad, a fistula following a properly performed enterostomy is rarely ever seen.

The clamp is now removed from the rectal tube and the bowel contents with quantities of gas are allowed to drain into a basin placed beside the patient. It is now easy to return the collapsed loop into the abdomen. The wound is closed by interrupted figure of eight sutures of chromic gut and the skin and superficial fascia with silkworm sutures. The ends of the middle silkworm suture are left long and tied about the tube. The tube is irrigated at least hourly with water injected without pressure, or oftener, should the drainage cease. Let me urge the constant attention to the tube, beginning immediately after operation in order to encourage free and constant drainage.

RATIONAL TOPICAL SKIN THERAPY*

By OSCAR L. LEVIN, M.D., NEW YORK, N. Y.

Read before the Dutchess Putnam Medical Society, at a meeting held December 10, 1930.

THE skin should be looked upon as an important organ of the body that has definite functions to perform which normally co-operate with the functions of the internal organs. Disorders of the skin may affect the health of the rest of the body. Constitutional disturbances may produce abnormal cutaneous conditions. The origin of the great majority of skin diseases is internal dysfunction or cutaneous predisposition induced by a constitutional state. Even in local infections, like ringworm, impetigo, and furuncles, or dermatitides excited by external chemical or physical agents, the types and degrees of cutaneous reactions vary with the constitution of the individual affected.

The purpose of treatment is to cure or relieve, whether a diseased condition is constitutional or limited to the skin. To be scientific and systematic is essential for the physician who applies practical therapeutics. Therefore, in the scientific treatment of skin diseases measures are employed to (1) correct the physiology of the internal organs, (2) remove the local excitant, (3) eradicate the local predisposing factors, and (4) apply special local therapeutic measures which may be mechanical, chemical, and physical.

It is my purpose to devote this paper entirely to an explanation of the rationale for the application of the most commonly used topical applications. These are powders, lotions, pastes, creams and ointments.

In the treatment of an eruption it must be remembered that the various lesions represent visible manifestations of pathological changes in the structure and function of the skin. The local treatment depends upon a clear understanding of the pathology of the lesions and its correct interpretation to enable the proper application of remedies to rectify the abnormal changes.

Take, for instance, the simplest form of skin reaction—erythema simplex. When such a lesion is examined under the microscope it is found that the changes consist essentially of a dilatation of the blood vessels in the corium and papillary bodies, serous exudation, migration of leucocytes and diapadesis of the erythrocytes into the surrounding tissues. These changes manifest themselves clinically by redness and slight elevation of the skin. Because of the dilatation of the blood vessels there is an increased amount of blood in the affected skin resulting in increased heat, and as a result of the engorgement, the increased tension and irritation of the cutaneous nerves, there are subjective complaints of burning and itching.

Excellent agents for the correction of such acute simple lesions are powders which, when dusted on the skin, act by virtue of their physical properties. Fine, compactly arranged granules cover and protect the underlying tissue from external irritation and afford increased surface for heat radiation from the skin. This increased radiation and the capillary attraction to remove the fluids quickly cool the skin, blood vessels are contracted and the congestion relieved. Powder is, therefore, valuable for the protection, cooling and drying of the skin.

The most active powders are the mineral ones like zinc oxide, zinc stearate, magnesium carbonate, prepared chalk, bismuth subnitrate, terra silica and kaolin. The first are finer and more soothing while the last are heavier and take up large amounts of fluid, and are especially valuable in the presence of fluid discharges. However, the gradual admixture with the fluid causes a caking so that they must be more frequently removed and applied.

The vegetable powders like starch, corn, rice and lycopodium are also valuable but must be employed with caution. The granules tend to swell, ferment, and decompose when mixed with sweat or other fluids so that they eventually irritate the skin. They should not be allowed to remain for a long time on the skin, especially in a caked condition, as they may eventually roughen the skin, obstruct the pilo-sebaceous follicles, and predispose to pyogenic infection.

For purposes of antisepsis, boric acid, salicylic acid and calomel are added, while phenol and menthol are used for antipruritic and cooling effect.

If there is a more inflammatory reaction as in the case of eczema, we advise lotions which are essentially fluids containing powders. In acute papular and vasicular eczema and allied conditions, there is a catarrh of the skin. The changes observed are at first similar to those in the erythemas. But the reaction tends to be accentuated, resulting in congestion, an infiltration of round and polynuclear cells in the corium, swelling with œdema in the corium and epidermis, extracellular and intracellular œdema of the epidermal cells, with ballooning and gradual breaking down of the cells to form cavities of broken down cells—microscopic vesicles. Thus to the naked eye there are redness, swelling, solid elevations—

papules, elevations containing fluid, vesicles, and with escape of fluid there is moisture.

Lotions should be shaken and spread on the skin with cotton or a soft camel-hair brush, and allowed to dry. The evaporation of the liquid cools the skin while the coating of powder remaining continues its action. Glycerine is frequently added for its hygroscopic action and also to keep the powder more continuously in contact with the skin. It is omitted or reduced in cold weather because it may make the skin cold and clammy. The proportion of glycerine is increased in warm weather but its strength is rarely above ten per cent, when used for acute inflammations, as it may become irritating. The fluids are usually lime water and rose water. When too drying, distilled water may replace the lime water. Alcohol is sometimes added for antiseptic, cooling and drying purposes.

No field of medicine requires the services of a scientific pharmacist more than does dermatology. The quality of the ingredients as well as the care with which the prescriptions are compounded are of great importance. A simple, and probably the most frequently used and useful lotion is the calamine and zinc oxide lotion.

Rx.	Prepared calamine	8.0
	Zinc oxide	8.0
	Glycerin	12.0
	Lime water	15.0
	Rose water, enough to make	120.0

Even this simple lotion may show a difference in appearance and in its effect on the skin when not properly prepared. In this preparation, chemically pure zinc oxide and a fine pink prepared zinc carbonate (prepared calamine) should be sifted through a fine sieve. The mixture should then be rubbed with the glycerin and a small amount of the official limewater added to make a fine paste. Then the rest of the limewater and rosewater are added. The zinc oxide and calamine act as a powder after the waters have evaporated and the glycerin soothes and keeps the powder in contact with the skin. Menthol and phenol should be rubbed together and a small amount of alcohol added to aid the liquefaction. These are used for anti-pruritic and cooling effect.

The rupture or tearing open of the vesicles results in the escape of fluid on the surface of the skin. When this desiccates, crusts result. In crusted cutaneous conditions it becomes necessary to remove the crusts before attacking the underlying pathological tissue. Watery solutions applied as wet dressings are not only efficient cleansing agents, but they also act to reduce inflammation. A pad containing several layers of gauze is soaked with a weak solution like a one to ten Burrow's solution, a two per cent boric acid solution, or a saturated solution of magnesium sulphate, and then applied to the inflamed crusted surface. The fluid softens and macerates the crust which is gradually detached. The gauze should be saturated and more fluid frequently added to maintain sufficient moisture. In acute conditions the gauze should not be covered with an impervious material like gutta percha or rubber tissue, as this prevents evaporation and causes retention of heat which results in irritation of the acutely inflamed skin. On the other hand, it may be desirable to stimulate rapid softening and breaking down as in the presence of chronic inflammations with firmly adherent thick crusts, or when hasty necrosis is desirable as for furuncles. In such cases the impervious covering may be justified. Subsequent to the removal of the crusts the lesions should be treated as suggested for acute vesicular eczema.

Cutaneous conditions of several weeks' duration usually show cellular infiltration, changes in the collogen, hypertrophy of the rete pegs—acanthosis, hypertrophy of the epidermal cells and especially of the cells of the stratum corneum resulting in parakeratosis and hyperkeratosis. The skin appears dark red, thickened and scaly. Both lotions and pastes act well in such cases. The latter are fat preparations containing high percentages of powder.

When spread on the skin, the fat covers, protects, softens and lubricates the skin. The incorporated powders favor absorption of secretion, radiation of heat, and relief of congestion. Lassar's paste contains approximately fifty per cent of powder—equal parts of zinc oxide and powdered starch—and fifty per cent of fat—usually vaseline. This makes a thick paste that is more or less difficult to spread and it is more practical to reduce the powder to twenty-five to forty per cent without affecting the efficiency of the preparation. Salicylic acid, in one to three per cent strength, is frequently added as a mild antiseptic, to prevent fermentation of the discharges and to dissolve the abnormal surface scales. When secondary pyogenic infections have caused pustule formation, an antispetic like ammoniate of mercury may be added to the paste preparations. Other drugs like tar, mercury, and sulphur are added for specific reasons.

Cold cream makes a splendid fat base for pastes and enhances the value of the paste by cooling and reducing congestion.

Creams are fatty preparations that contain water—usually about twenty per cent. The fat covers the skin, the water in the cream

evaporates, the cream then absorbs water from the skin, especially if there is inflammation, reducing the temperature of the skin. This action is the reason they are called cold creams. Many of them contain anhydrous lanolin or aquaphor to aid in taking up water from the skin. Petrolatum makes a good base as it does not decompose. Wax may be added to make creams firmer. Since they tend to become rancid, it is necessary to add a mild antiseptic such as boric acid to the fat and water, while some such perfume as rose water may be added for esthetic purposes.

The chief uses of creams are to cleanse, to protect from external irritants, to supply oil and fat where the natural excretions are deficient, and to serve as a base.

They are spread on the skin and covered with a powder or gently rubbed into the skin, making it soft, smooth and lustrous. They are excellent non-drying solvents and may be used for dry, scaly, chapped and cracked skin.

For chronic lesions of the skin, ointments are most frequently employed. These consist almost entirely of fat with drugs added for medicinal action. When fat is spread on the skin it covers it like an impervious material and prevents escape of fluid and causes retention of heat. The ultimate result is irritation which stimulates the sluggish skin. Circulation is improved, absorption is favored, resulting in a tendency to the formation of new normal cells. Surface scales and crusts are also softened and rendered more easily removable as the surface cells swell as a result of the penetrating action of the fat.

Drugs employed in ointments for specific medicinal purposes are varied. Tar, sulphur and resorcin are commonly employed for antipruritic, antiseptic and keratolytic action; salicylic acid to dissolve hyperplastic tissue; chrysarobin and pyrogallic acid as reducing agents and caustics, and so on. Many of the drugs that are incorporated act as keratoplastics when present in small amounts, and as keratolytic agents when more concentrated.

As ointments are used in chronic conditions and where stimulation is desirable, rubbing in of the preparation is advisable. In old, obstinate, resistant, thickened patches, the action of an ointment may be increased by covering it with impervious material like oiled silk. If the irritation is excessive, an acute inflammation may supervene. This result is often desirable and is subsequently treated as an acute eczema.

When surface action for a dry condition is the aim, petrolatum is good. Lanolin or goose grease may be added to increase penetration, anhydrous lanolin is used for moist areas, and wax is incorporated when the preparation needs stiffening.

Descriptions of the procedures pursued in the treatment of eruptions in two patients recently observed are appended as illustrative examples.

CASE I

In the case of G. J., a schoolboy, who had suffered from dermatophytosis (eczematoid ringworm) of his feet, acquired at camp about five months ago, the following local applications resulted in a cure in a little over two weeks.

At the first examination the patient was unable to walk and was lying in bed. The plantar surfaces of the feet were covered with large, elevated, inflammatory, pustulo-bullous patches with tense, sharply-demarcated borders. The feet were swollen, oedematous, and showed discrete and aggregated small and large vesicles, pustules and scaly patches. Scattered over the upper extremities and buttocks there were numerous small, red, scaly follicular papules. It was evident that the patient would do best in bed to prevent local irritation and pressure in order to obviate further dissemination of toxin through the circulation, which was already happening as evidenced by the trichophytides of the extremities.

Before beginning active treatment dirt and adhesive plaster were removed with benzine and a soap and water foot-bath. A wet dressing of a 1 to 2000 solution of potassium permanganate was kept constantly applied during the day. This acted as an antiseptic; it kept the discharges free of odor, and by radiation, evaporation and slight astringent action, reduced the oedema, swelling and infiltration. At night an ointment, containing petrolatum as a protective emollient base, three per cent each of salicylic acid and benzoic acid for antiseptic, antifermentative and slight keratolytic action, and one-half of one per cent phenol for antipruritic effect, was applied. Precautions were observed against covering with a tight dressing to avoid skin gangrene from the phenol. Two days later the acute inflammatory reaction had subsided and wet dressings were discontinued. A cooling evaporating lotion of alcohol with three per cent each of salicylic acid and resorcin was then dabbed on several times during the day, to increase keratolysis. The feet were also allowed to remain in the sun and fresh air to aid desiccation. The ointment was continued during the night. At the end of five days the infected skin had completely desquamated. The mild ointment was applied during the day and night. Two days later when the denuded areas were no longer tender a stronger salicylic acid and

benzoic acid ointment was applied, especially on the surrounding old, hyperkeratotic, scaly patches and the nails. When last seen about two days ago, the patient walked into the office without any discomfort and the skin was completely healed but for slight redness, denudation and slight scaling. At present the salicylic acid and benzoic acid ointment together with three per cent carboneol (technical coal tar) is being rubbed in twice daily. The tar was added as an antipruritic and keratoplastic.

The generalized trichophytides were treated by means of frequent applications of the following lotion:

Carbolic acid	2.0
Menthol	1.0
Zinc oxide	8.0
Magnesium carbonate	12.0
Glycerin	2.0
Oil of sweet almond	30.0
Lime water	60.0
Rose water enough to make	240.0

Directions: Shake, pour into saucer and dab on skin.

To prepare this properly the oil should be combined with the lime water by shaking it vigorously in a bottle. The powders are mixed together and to them the oil and lime water mixture is gradually added. The carbolic acid and menthol are dissolved in a small amount of alcohol, and finally enough rose water is added to make the eight ounces.

This makes a smooth, white preparation, and shows no separation in the finished product, even after standing for a long time.

CASE II

Another common skin disease is psoriasis, which usually calls for judicious selection of proper local therapy. In one instance, M. K., a married female, had had recurrent attacks of psoriasis. She presented a generalized eruption of mummular and geographical patches that were covered with thick layers of scales and crusts. Although psoriasis is dry and not itchy, it is at times moist and crusted because of acute congestion which may be induced by irritation as from overzealous stimulating treatment. Therefore, in this case, it was first necessary to remove the thick crusts. Subsequently the psoriasis itself would require treatment. The main changes in psoriasis consist of hyperkeratosis and parakeratosis of the horny cells, uniform hypertrophy of the rete pegs — acanthosis, small abscesses and increased air in the epidermal cells. There are also congestion and infiltration in the upper corium and papillary bodies.

After a cleansing, soothing alkaline bath the following protective, soothing, softening cream was applied for several days:

Zinc oxide	30.
Oil of sweet almond	30.
Anhydrous lanolin	6.
Limewater	12.

In the preparation of this cream the zinc oxide is rubbed with oil. The lime water is then added little by little until it emulsifies. Then the lanolin is added. This should be a smooth product.

At the end of this period when the crusts were softened and loosened, five per cent of salicylic acid was applied to hasten the falling off and melting away of the covering epidermal cells. Subsequently when the lesions were clean, exposed and less inflamed, a two per cent ointment of chrysarobin was rubbed in twice daily. Chrysarobin acts as a reducing agent. When prescribing this drug, patients should be warned of the danger of conjunctival irritations, staining of clothes, and untoward secondary inflammation. Under this method of attack the lesions faded and with the onset of a slight increase in the redness a soothing calamine and zinc oxide lotion was prescribed for the general skin and Lassar's paste for the folds of the joints.

The question is often asked—Why not use the Roentgen rays in the treatment of psoriasis? It has been the writer's experience that although marked improvement and rapid disappearance often occurs in psoriasis with this form of skin therapy, it is advisable not to employ the Roentgen rays except for occasional localized patches. In a disease like psoriasis which is frequently recurrent, it is often noted that patients who have had *x*-ray therapy later tend to resist the action of the rays, and recurrences are more persistent and accompanied by intense itching.

Although it was not intended to discuss any other form of external treatment, it seems advisable to say that in *x*-ray therapy of the skin, great advances have been made, and that much benefit often occurs from the careful application of properly measured doses of the ray by the experienced dermatologist who properly diagnoses the clinical lesions and is able to interpret these in terms of their histopathology and knows how to obtain the best biological effects without injuring the integument.

In conclusion it is reiterated that cutaneous therapeutics cannot be divorced from general medicine. Every weapon in our medical armamentarium should be employed in curing the patient, as well as the skin. The attempt

has been made in this paper to describe briefly the simple local rational measures that may be used by the physician who does not practice dermatology as a specialty. For this reason specialized methods of procedure and skin physical therapy are not included. Success in the management of a case often depends upon the proper preparation of the products applied, and co-operation with a good pharmacist is valuable. Emphasis should be placed on the factor that to obtain the best results by means of topical treatment the physician, after making his dermatological diagnosis, should utilize the various local applications to correct the abnormal pathology and encourage the return of normal skin.

FUNGOUS INFECTIONS OF THE FEET; OBSERVATION OF THEIR INCIDENCE IN A SCHOOL IN NEW YORK CITY*

By GEORGE C. ANDREWS, M.D., and FREDERICK W. BIRKMAN, M.D., NEW YORK, N. Y.

DURING the past decade dermatologists in particular, and other observers as well, have been aware of an ever increasing number of cases of fungous infection of the feet and hands. The practice of making microscopic and cultural examinations of fragments of the skin in suspicious lesions often reveals the presence of fungi in eruptions which a few years ago were probably labeled pompholyx, eczema, or perhaps dermatitis venenata. However, more accurate diagnosis does not alone account for the marked increase in the number of cases of ringworm of the feet and hands. There has undoubtedly been an actual increase in the incidence of the condition. It has been found that various kinds of fungi may be responsible for clinically similar skin lesions, and that the appearance of the primary lesions may be markedly altered by the secondary invasion of pyogenic bacteria.

Recent Reports of Incidence

The increasing importance of fungous infection has led to numerous clinical and laboratory studies of its incidence, some of which have been reported in the literature. A few of the most recent studies on the subject are here briefly summarized.

In 1925, Hulsey and Jordan[1] reported the results of the examination of the feet of 100 medical students at the University of Pennsylvania. They found 67 percent with clinically positive dermatophytosis, 49 percent positive microscopically, and obtained positive cultures in 5 percent. The students were from all parts of the United States but residence bore no relation to the incidence of the condition in this series. A small portion gave a history of previously active dermatophytosis.

During 1928 and 1929, as a part of the routine physical examination of freshman students at the University of California, the University physician looked for clinical signs of ringworm infection of the feet. Among 3100 students examined the clinical incidence of the disease was 53.5 percent in the men and 15.3 percent among the women, showing that the disease was common among high school and preparatory school students. At the end of the year, a number of the students were reexamined, when among 1000 men 78 percent were found clinically positive, an increase of 25 percent, and among 997 women 17.3 percent showed clinical evidence of ringworm of the feet. The conclusion was that the increase of 25 percent in the incidence of the disease among the men was due to the use of common showers, swimming pools and apparatus in the gymnasiums, during the interval between the two examinations; no special precautions having been taken to prevent the spread of ringworm. That the rate of increase among the women was much smaller, only 2 percent, in this interval, was explained by the fact that they used a new gymnasium with new equipment and were required to wear slippers in all activities. They even wore rubber slippers while in the swimming pool.[2]

In 1930, Beckett reported the results of an examination of the feet of patients in the Veterans' Hospital at Gulfport, Mississippi. Two hundred and fifty-nine were examined, of whom 98, or 37.8 percent, presented clinical manifestations of fungous infection of the feet.[3]

Similar observations of the prevalence of fungous infections are being reported from all parts of the world. Recently, a study has been reported from Peiping Union Medical College, Peiping, China.[4] Clinical, microscopic and cultural examinations were made of the feet of 204 individuals. Fifty-four or 25 percent of the number examined presented evidence of active or latent fungous disease; 150 showed no clinical evidence of the disease but nevertheless 5 of these gave positive microscopic findings and 3, positive cultural findings.

In May of this year, Goodman[5] made a statis-

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 3, 1931.

tical report, showing the percentage of cases of eczema, acne and tinea among all patients in the dermatological service at the New York Skin and Cancer Hospital during recent years. Tinea was either eighth or ninth in the order of incidence of the most common diseases of the skin each year from 1913 to 1927, inclusive; while during 1928 and 1929 it rose to second place among all diagnoses, being exceeded only by eczema.

The Present Study

In order to shed some light on the incidence of this disease among students in New York City, we have undertaken a routine examination of the feet of a large number of public school and university students. The present report includes our findings in a clinical examination of a series of 520 public school boys between the ages of 14 and 20 years, and cultural studies of an additional group of 50 boys in the same school.

Clinical Observations.—The clinical examination consisted simply of a careful inspection of both feet,—particular attention being given to the webs between the toes and to the skin at the junction of the toes and the balls of the feet. The condition of the toe nails was also noted. However, since it is practically impossible to differentiate nails infected by fungi from nails affected by other diseases without the aid of microscopic or cultural study, we did not presume that the student had onychomycosis unless there were also positive clinical signs on the skin. In addition to the inspection, each boy was questioned as to whether in the past he had noted signs of fungous disease of the feet.

The results of our examination were as follows:

Total number examined 520
Number showing clinical signs of fungous disease .....65 or 12½ percent

A past history of active fungous infection was given by 31, or 6 percent. However, only 10 of this number showed any present evidence of infection.

Among the 65 positive cases, the disease was manifested chiefly by sodden, macerated or scaling epidermis of the webs between the toes, or by small fissures in the skin of the webs or beneath the toes. Of these positive cases, 20 also presented one or more of the abnormalities of the toe nails which are so commonly observed in ringworm of the feet. These were chiefly thickening and discoloration of one or more nails, longitudinal striations or ridges, transverse grooves, friable and irregular edges, and white powdery scales heaped beneath the nails.

The great majority of the subjects examined were not even aware of the presence of these relatively latent forms of the disease. Only 4 in the entire series presented a more active form of the disease, namely, groups of small vesicles on the toes or soles.

It will be noted that the percentage of clinically positive cases is small (12½ percent) in comparison with the percentages obtained in both studies among college men, which were 67 percent and 53 to 78 percent respectively. The geographical factor may be of some significance, but we are inclined to believe that the incidence of the disease is fairly uniform throughout the country. One factor that seems to be of importance in accounting for the relatively low percentage of positive findings in our series is the difference in the social status and the hygienic habits of those examined. Probably the feet of most of the college students were subject to frequent bathing and the use of common showers, swimming pools and gymnasiums. The group of New York boys, on the other hand, were students in a trade school, which they attended only one day a week, being otherwise variously employed during the other days. There are no athletic activities in the school, no swimming pool, no showers and hence no common exposure. The students were in a large measure from families rather low in the social scale. Upon examination, the feet in a large majority of cases showed no signs of the use of soap and water. In fact, it was especially noticeable that most of the positives were among the cleanest feet; whereas other feet with loose moist dirt between the toes, almost enough soil for growing vegetables, showed no clinical evidence of dermatophytosis. Another fact to account for the relatively low percentage of clinically positive cases in our group may have been the younger age of the boys compared with that of the college students.

Cultural Examination.—In addition, we made a cultural examination of the toe nails and of the skin between the toes of an unselected group of 50 boys. Clippings from several toe nails, particularly from nails which seemed most likely to be infected, were taken from each boy. The fragments were cut into small pieces, washed for five minutes in 95 percent alcohol and planted on honey agar slants. Three or four tubes were planted with four to six pieces of nail in each tube, depending upon the amount of material available. Cultures from the skin between the toes were taken after first sponging it with alcohol by scraping the selected area with a scalpel. The loosened epidermis was planted directly with the knife on the agar slants, three or more tubes being planted in each case. As growths appeared in the primary cultures, subcultures were made on appropriate media for purposes of identification.

The following is a brief summary of our cultural findings: Of the 50 boys examined, 44 were clinically negative; the remaining 6 were clinically positive, presenting chiefly white sodden areas of

macerated epidermis in the interdigital skin, or fissures between the toes. There were no cases of the more severe types of ringworm infection among them. In the 6 clinically positive cases, the results of the cultures were:

(1) In one case a growth of Trichophyton gypseum was obtained in one nail culture and in one skin culture, the other cultures from the skin and the nails failing to grow this organism.

(2) One case presented a growth of Trichophyton gypseum in one skin culture. The other skin tubes and all the nail tubes failed to develop the organism.

(3) The cultures in two cases developed growths of moniliae, one from the epidermis alone; the other from both the epidermis and the nail.

(4) The cultures in two cases presented growths of cryptococci, the one from the skin alone; the other from both the skin and the toe nail.

The results of the cultures made in 44 cases in which the feet showed no definite signs of fungous involvement, were:

(1) One growth of Trichophyton gypseum occurred in a skin culture. The remaining skin tubes and nail tubes failed to grow this organism.

(2) Moniliae appeared in 7 cases from toe nail cultures and in 2 cases from skin cultures.

(3) Cryptococci grew in 5 cases in the cultures of both the skin and toe nail; in 10 cases in the cultures of the toe nail alone; and in 4 cases in the cultures from the skin alone.

Discussion

We do not stress the importance of our cultural findings. Statistical analysis in any study of this kind illustrates the possibilities of error. If one depends upon cultures and finds that positive cases show dermatophytes in only one out of 6 or 8 tubes, it is probable that a survey by this method gives too low an incidence. If, on the other hand, one depends upon inspection, it is quite likely that one will include cases of dermatitis not caused by dermatophytes.

It seems evident that the mere presence of pathogenic fungi on the skin is not sufficient to cause active invasion; just as the presence of staphylococci or streptococci on the skin or in the throat may not necessarily result in the development of furunculosis or tonsillitis. None of the moniliae found in our series was Monilia albicans, the variety which has been definitely shown to be pathogenic. Nor can we conclude that the cryptococci were pathogenic. Trichophyton gypseum, which undoubtedly is pathogenic, was found on apparently normal skin in one case. However, this finding is by no means unique. In a series of examinations of the normal skin in 36 individuals, Williams[6] found dermatophytes in two cases. Cornbleet[7] made examinations of scrapings from apparently normal interdigital skin with three positives out of 100 examined. Burgess[8] made a similar study of the normal interdigital skin of 100 individuals, but failed to find ringworm fungus of any kind.

To us, the most interesting fact revealed by our study is the small percentage of clinically positive cases of ringworm of the feet among our particular group of public school boys in comparison with the incidence found in similar studies at the University of Pennsylvania and the University of California. Our results seem to substantiate the general opinion that the disease is spread chiefly by exposure of the bare feet to floors in common showers, dressing rooms, swimming pools and the like. They also agree with the observations of Sabouraud, Kaufman-Wolf, Williams and others that tinea of the feet is found less often among the poorer classes than among the well-to-do.

THE DIAGNOSIS OF INTRACRANIAL HEMORRHAGE IN THE NEW-BORN*

By CLIFFORD G. GRULEE, M.D., CHICAGO, ILL.

Introduction

IN INTRODUCING this subject, I should first like to quote passages from two recent articles. Peterman[1] speaking of intracranial hemorrhage makes the following statement, "It is responsible for most of the convulsions which occur in the first year and for almost all of the hemiplegias, diplegias, paraplegias and paralyses found in childhood." I believe that this statement is one which is commonly held by pediatricians and I doubt very much if it is justified. In the first place, most of the convusions in the first year of life certainly beyond the new-born period cannot be attributed to hemorrhage and I wonder if many of the nervous disorders which have been attributed to intracranial hemorrhage may not be rather on the basis of a congenital brain defect than upon destruction through a hemorrhage at the time of birth.

The second quotation I should like to give you is that by Donald Munro[2], who has based his conclusions on 117 cases, which have been carefully observed over seven years, which I think represents the nearest approach that I have found to an adequate, or nearly adequate observation of these cases, he says, "The diagnosis of intracranial hemorrhage of the new-born must be expanded to include cerebral edema and fracture of the skull and should be stated as "cranial and intracranial damage in the new-born." It seems to me that this second quotation is even more interesting than the first. It is very evident that Munro recognizes our inability at the present time, to make a definite diagnosis of intracranial hemorrhage and tries to cover the whole subject with a blanket. I am just wondering whether such a proposal affecting adult life would not meet very short shrift. The second statement calls attention to the ignorance concerning conditions at this age, but if we accept the second statement, we must admit that the first statement (that of Peterman) is exaggerated. I would even go a step further than Munro and include cerebral congestion and anemia as conditions which might produce symptoms very akin to intracranial hemorrhage. The problems which present themselves then are first, "What are the symptoms and physical signs of intracranial hemorrhage?" Second, "How do they differ from those of other conditions with which they may be confused?" Third, "If this difference is not sufficiently marked, by what means may we advance our knowledge of the subject in order to obtain the desired information?"

SYMPTOMS

Let us take first those symptoms which are commonly associated with the diagnosis of intracranial hemorrhage. Nearly every one who writes on this subject mentions lethargy. It is true that in the early stages, lethargy is a symptom. The child is drowsy, hard to arouse and if this symptom continues in increasing degree, it may lead to coma, but anyone who has had much experience with the care of newly-born infants, must realize that lethargy is a common state. This is particularly true of premature infants. It is not uncommon to have to exert oneself even to the point of mild punishment in order to arouse a perfectly normal newly-born infant sufficiently so that it will nurse. We therefore may be assured that ordinary lethargy is not in any way peculiar to hemorrhage; it is however, frequently met with in that condition.

The same may be said of newly-born infants refusing to nurse. Many of them cannot be aroused sufficiently to nurse the breast and when they are, they perhaps nurse two or three times and then stop. Both these conditions are particularly frequent in the newly-born infant at the age in which intracranial hemorrhage first produces symptoms, that is, on the first, second and third days.

A great deal has been said about the whining cry and I think with reason, but the whining cry may be heard in other conditions. It is present in infection. It is often present in those children who have had very little nourishment. Neither of these conditions, however, manifests itself in the first, second or third day of life as a rule, so that a whining cry may well represent at this time some cerebral irritation. One should, however, distinguish between cerebral irritation and intracranial hemorrhage.

Coma is more definitely a symptom of intracranial hemorrhage than any of the above mentioned, but coma comes almost without exception in fatal cases, so much so that one may question the diagnosis if the infant recovers. These are the particular symptoms which have been suggested in the diagnosis of intracranial hemorrhage and of these we find but one at all characteristic and that characteristic only of a severe degree with probable fatal outcome.

Physical Findings: Certainly the majority of the cases of cephalhematoma are not associated with intracranial hemorrhage. Over-riding of the sutures of the skull is suggestive in the presence of marked trauma. Such over-riding, however, must be marked representing a molding process of a severe degree. Examination of the anterior fontanelle leads frequently to very sug-

gestive evidence. Bulging of the fontanelle is suggestive of increased pressure within the cranial cavity. It is true that this pressure may be due to something other than intracranial hemorrhage. A slight degree may be due to edema, or to skull fracture, or on the third day of life, it is conceivable that such bulging of the fontanelle may be due to meningitis. The only difficulty regarding the bulging of the fontanelle is that where there is pressure and appreciable bulging of the fontanelle, there is likely to be marked destruction of the cerebral cortex from the hemorrhage and the outlook is quite unfavorable. Intracranial hemorrhage may occur, however, with a depressed or a flush fontanelle. It should be noted, however, that two difficulties come with respect to the fontanelle. One is, that in many newlyborns, the fontanelle is quite small and the question of bulging cannot be determined because of this. This is true in perfectly normal infants. Again, where hemorrhage is subtentorial, bulging of the fontanelle is an unusual feature.

Something can be learned regarding the condition of the child from a general observation of its appearance. Pallor is of frequent occurrence especially immediately after birth when a severe case of intracranial hemorrhage is often associated with asphyxia pallida. Another sign which is suggestive of intracranial hemorrhage is continued cyanosis of a mild degree. We are speaking now of course, of the first two or three days of life. Such a cyanosis is not uncommon at this time in the most severe forms of asphyxia livida, or occasionally in severe cases of congenital heart lesions where the right side of the heart is largely involved. Pallor is a much more suggestive symptom than is cyanosis, but neither can be regarded as more than suggestive since both are to be encountered in many other conditions.

When we come to look into the question of the neuro-muscular apparatus, we are confronted with certain barriers to diagnosis which are not encountered after this period of life. Focal signs are practically absent. When convulsive seizures occur on the right side they are not indicative of a lesion on the left side of the brain. Like as not, if the child dies, the autopsy findings will reveal that the lesion is on the right side and not on the left. No dependence either as to location, or kind of lesion is to be placed on the focal signs. Eye symptoms are peculiarly unreliable. Careful observation of the optic disc in all suspected cases (over a number of years) both by one of my associates and by one of the competent men of the ophthalmology department, failed to reveal any change that could be determined as peculiar to intracranial hemorrhage, or to an increased intracranial pressure at this age. The retinal hemorrhages noted cannot be regarded as especially significant since they are frequently associated with conditions other than intracranial hemorrhage, or may be present in perfectly normal infants.

Flaccidity of the muscles is certainly more suggestive than rigidity. The newly born infant is physiologically spastic as compared to later age. This is probably to a large extent, due to its cramped quarters in utero. For instance, it is not uncommon to see a child born in frank breech presentation stay for some days with legs extended at knees and sharply flexed at the hips, held along side the body, so that one wonders whether there is not a dislocation of the hip present. If one is to interpret rigidity as a sign of intracranial hemorrhage, one must be very sure that he is conversant with the different phases of rigidity as it appears in the normal newly born. It is extremely hard sometimes to say what is normal and what abnormal. *Muscular twitchings* too are given as a sign of intracranial hemorrhage, but twitchings of the muscles at this age are of rather frequent occurrence and do not always, by any means, usually represent anything especially abnormal. Where the twitching is occasional and transient, the likelihood is that there is nothing wrong. Where on the other hand there is continual twitching, especially if that is located in one part of the body and not in others, such as in an arm or leg, the probabilities are that there is some cerebral disturbance. *Convulsions* are a fairly definite indication of irritation of the cerebral cortex at this age. While I know there is some controversy as to the anatomical region from which convulsions proceed, still from a practical standpoint, the connection between the cortical lesions and convulsions is so frequent that there seems to be a definite causal relationship. However, as I have called to your attention, convulsions by no means always indicate intracranial hemorrhages. I have seen at least two infants on which I had made the diagnosis of intracranial hemorrhage both of which had convulsions and twitchings, one had also a distinct and marked unilateral perspiration. At autopsy, no signs of anything pathological except congenital heart lesions were found in either. In both instances the chief determining factor in diagnosis was the presence of convulsions, though in one a strongly suggestive phenomenon was the sweating. It is very evident from these facts that all cases of convulsions in the newly born are by no means due to intracranial hemorrhage. The chief cause of convulsions in the new-born is, however, most probably intracranial hemorrhage.

There seems, quite naturally, to be supreme confidence in information obtained by means of lumbar puncture, but I would call your attention to the fact that lumbar puncture at this age has not the value as a diagnostic measure that it has in older individuals. In the first place, where an intracranial hemorrhage is strongly suspected,

one hesitates to place the child in the position which is most favorable for lumbar puncture, but such a position is necessary if one is to be successful, as a little experience will definitely prove. However, if the procedure may be justified either from a diagnostic or therapeutic standpoint, then there is always the excuse for taking the chance. It is not here the time nor place to discuss the therapeutic advantage of lumbar puncture. As to its diagnostic advantages interpretation must be hedged in by many qualifications. In the first place, it does not take long for one who has had much experience with lumbar puncture at this age to come to the conclusion that bloody fluid is not always the result of intracranial hemorrhage previous to the time of puncture. If one be honest with himself, or perhaps I might say, in the process of being honest with myself, I have come to the conclusion that my technique and that of my assistants in this procedure is not such that we can be assured that bloody fluid is not produced by the puncture rather than by a foregoing intracranial hemorrhage. It is extremely easy to get blood from the spinal canal of newly born infants by puncturing one of the veins which are so luxuriant on the inner wall of the canal, or even by puncturing the venous sinuses in the bodies of the lumbar vertebrae. However, given a bloody fluid, if it be examined immediately and crenated cells found, specially if these be in large numbers, we have direct evidence of hemorrhage into the spinal canal. This hemorrhage may come from several sources. It may come from a spinal rather than a cerebral lesion. It may come from diapedesis rather than rupture of a vessel. There may be no blood even though a large hemorrhage is present. The amount of blood in the spinal fluid is by no means indicative in a given case of the size of the hemorrhage. If therefore, we are to derive any special knowledge from lumbar puncture, we must be very sure of our technique and we must examine an absolutely fresh specimen. The absence of blood does not mean absence of hemorrhage, nor does the quantity of blood determine the extent of hemorrhage. One other point regarding spinal fluid, the presence of xanthro-chromatic fluid in the first, second or third days of life is much more likely to be due to icterus than to decomposed blood. It is perfectly easy to determine this by laboratory tests, but one should always bear it in mind. A xanthrochromatic fluid from intracranial hemorrhage would not be expected certainly until the lapse of several days.

Cisterna puncture as advocated by Loeber,[3] would seem to be a much more rational procedure if we are to obtain spinal fluid from which we may draw conclusions. In the first place, we can be sure that bloody fluid obtained in this way if it came from hemorrhage into the nervous system at all, came from hemorrhage from above. In the second place, such puncture is not likely to be associated with hemorrhage produced by the trauma of the puncture. It would, however, be wise in estimating the value of such fluid to limit it with the same restrictions as in examination of spinal fluid obtained by lumbar puncture.

Another procedure which conceivably might be of some value in cases where hemorrhage from the choroid plexus is suspected, is puncture of the lateral ventricle through the anterior fontanelle. I have never attempted this because I have never been able to differentiate with sufficient accuracy lateral ventricle hemorrhage from that in other parts of the cranial cavity. On one or two occasions, however, I have been able to obtain the blood from over the surface of the parietal lobes by introducing a needle through the anterior fontanelle under the parietal bone directing it parallel with the surface of that bone. This procedure is not to be advocated unless one is pretty sure that the hemorrhage is located in that area.

Just a word regarding the evidence in later life of intracranial hemorrhage of the new-born. We are prone to think that every spastic paralysis of a chronic nature in childhood and later life, especially if it gives a history of existing from birth, or early infancy, has its origin in intracranial hemorrhage. One wonders just how much we are justified in taking this position. How do we know for instance that the condition is not primarily a brain defect with secondary hemorrhage over that portion of the brain? How can we be sure that encephalitis, local or general, is not responsible for many of these conditions? What reason have we for thinking that the majority of cases of spastic diaplegia or Little's Disease are due to intracranial hemorrhage? It seems to me that we have too readily blamed this condition for a multitude of ills that may have their basis on some other quite different disease process.

If we review carefully the facts, we find that there is very little in the way of positive information which is to be gleamed, in other words, diagnosis rests not upon single facts, but upon a careful weighing of the whole situation and mature judgment. If we stop to think, we will recognize the fact that not only hemorrhage but other pathologic conditions can cause the symptoms referable to the cerebral cortex which practically means all the symptoms found in this condition. I am quite well persuaded from some experience that I have had that such evidence of cerebral irritation may be due to anemia, congestion, edema, hemorrhage or inflammation and the evidence of hemorrhage must be obtained therefore by examination of the spinal fluid, or by some other method not yet devised. As we

[3] Loeber, Maud, *N. O. Med. & Surg. J.*, 1931 (Feb.), *83*, 536.

have seen, the examination of the spinal fluid is not satisfactory, so that at the present time it is extremely difficult in many instances to make the diagnosis of intracranial hemorrhage of the new-born.

Let us now consider what conditions are likely to be confused with intracranial hemorrhage and whether or not we have definite criteria by which to judge as to their presence. Let us take first that condition which has been known for a long time as *hemorrhagic disease* of the new-born. The nature of this is unknown; that it is associated with a prolonged coagulation time without much change in the bleeding time of the blood is pretty generally accepted. We are scarcely justified in making a diagnosis of this condition until such evidence is at hand. In rare instances this condition may be associated with intracranial hemorrhage. I think we may well abandon any idea that intracranial hemorrhage causes the condition since no evidence in favor of this has ever been brought out. However, in the severe anemia produced in this condition by bleeding, there may be convulsive seizures and the entire picture of intracranial hemorrhage without such hemorrhage being present. A complete recovery can occur as the result of transfusion. Hemorrhagic disease however rarely puts in its appearance before the third day and consequently the hemorrhages occurring in this disease manifest themselves later than those in true intracranial hemorrhage of traumatic origin.

As to *sepsis* in the new-born, the problem is less intricate. Sepsis rarely manifests itself before the third or fourth day and is nearly always associated with fever. Convulsive seizures occur if at all, quite late and not early as in intracranial hemorrhage. The evidence of the route of infection may be present and all in all sepsis offers very little in the way of difficulty. *Icterus gravis* is in its modern conception very often an icterus associated with sepsis, so that much of what has been said regarding sepsis is true of icterus gravis. There is, however, one rare form of familial icterus gravis where there is marked involvement of the basal nuclei, it is conceivable that a differentiation between this and intracranial hemorrhage might be extremely hard or impossible. The problem in the *premature* is rather peculiar. In the first place, as we all know, premature infants are especially predisposed to intracranial hemorrhage. They are frequently afflicted with cyanotic attacks; they are definitely lethargic and are frequently hard to revive at the time of birth. The question we have is how much of the condition is on the basis of an intracranial hemorrhage and how much on the prematurity. As a matter of fact anyone who has had much experience with prematures and has followed those who died to the autopsy table, must recognize that many of the symptoms which have ordinarily been regarded as very suggestive of intracranial hemorrhage may be due to prematurity alone without any evidence whatever of hemorrhage. Certainly this is true of lethargy asphyxia livida and cyanotic attacks.

We might discuss in a few words a number of conditions which have been suggested as offering differences in diagnoses. Diaphragmatic hernia should in the majority of instances offer very little trouble. The same is true of atelectasis and pneumonia. An enlarged thymus has been offered as a condition which might simulate intracranial hemorrhage, but I think we should know first how to determine what an enlarged thymus is before we attempt to differentiate the the symptoms produced by it from those of intracranial hemorrhage. However, the difficulty of differentiating these two must be present only in extremely few cases. This may be said of the other conditions just mentioned. At first, one might think that congenital heart disease would offer no difficulty. On the other hand, as previously mentioned I have seen at least two cases with convulsions where the only findings at autopsy was congenital heart disease. It seems to me that if we are to attribute the symptoms to the heart lesion, we must conclude that these were produced by either congestion, or anoxemia of the cerebral cortex.

We come finally to those intracranial conditions which most often appear to be confused with intracranial hemorrhage, namely, edema, pressure from fracture and congenital brain defect. That edema is responsible for the picture which we have always associated with intracranial hemorrhage must be true in many instances. A prompt recovery of these infants with no evidence of physical or mental defect over a period of years, certainly speaks for a lesion which is irritating, but not destructive. The same may be said of depressed skull fracture. While this condition is relatively uncommon, it produces few if any symptoms after the depressed portion of the bone is raised. A simple fracture of the skull without depression unless it ruptures a blood vessel, is very unlikely to cause hemorrhages. I remember a small premature infant who was in a rather lofty incubator. The attending man felt that the infant was not getting sufficient air so he ordered that the door be left open. He had not reckoned upon the activity of the child. The premature precipitated itself on to the floor and received a long skull fracture over the vertex. This child suffered no apparent harm from the accident. The only evidence we had was the *x*-ray picture and the local evidence of crepitation which was hard to obtain.

As to the congenital brain defects I have long wondered. It seems altogether rational to suppose that a congenital brain defect capped by an edema ex vacuo would be an ideal place for

an intracranial hemorrhage. I confess not to have seen such a condition in a newly born, but such a condition would not seem to be in the majority of cases especially fatal, since there would be little destruction of the brain tissue and the results of the brain defect would show only later. I wonder if some of the conditions which we have been attributing to intracranial hemorrhage of the new-born are not really on the basis of brain defect.

Conclusions

In this brief summary, several points are brought to light. Primarily we are at present in no position to make a diagnosis of intracranial hemorrhage in the new-born in the majority of instances. Many of the cases which are now diagnosed hemorrhage are unquestionably due to other conditions. Information received from lumbar puncture is by no means always reliable and must be subjected to very critical judgment. The reason for this lies primarily in the failure of physicians to realize the difference in symptomatology between the newly born and the older infant. It also lies in the lack of study of this group of conditions at this age, and in complacence with our present knowledge which would not be tolerated at any other period of life.

THE KETOGENIC DIET IN THE TREATMENT OF EPILEPSY IN CHILDREN*

By FLORENCE E. WARNER, M.D., BINGHAMTON, N. Y.

THE ketogenic diet has been used in the treatment of epilepsy in children for about ten years, and the results seem sufficiently successful to justify this form of therapy. Complete disappearance of the seizures is produced in about 33 per cent of the cases so treated. (1) In a series of cases treated at the Mayo Clinic, of 141 patients treated more than one year 43 have been free of seizures for one to seven years, 32 definitely improved, having fewer and milder attacks, and 66 unimproved. Of 30 cases treated less than one year 11 have been free from seizures, 13 definitely improved and 6 unimproved (2).

The diet is most useful in the cases of frequent early or pre-epileptic attacks in which luminal is often ineffective. These consist of sudden periodic symptoms such as pallor, screaming, staggering, trembling and other manifestations of momentary duration. They must be controlled as soon as possible because each seizure produces changes in the brain which favor recurrence and tend to establish the epileptic habit. Cure can be achieved only by the prevention of attacks for a long time.

Since attacks in children cease or diminish during starvation with the development of acidosis, it was suggested by Wilder of the Mayo Clinic that a diet producing a similar acidosis might produce a similar effect. No definite basis for the successful results of the ketogenic diet has been established. The improvement accompanying either fasting or the ketogenic diet is associated with acidosis, ketosis, lowering of the blood sugar and diminution of the alkaline reserve. No one of these factors can definitely be credited with the results. Acidosis produced by the ingestion of a mineral acid such s ammonium chloride has no effect. Lowering the blood sugar by insulin shows no effect until the level of insulin shock is reached, when hypoglycemic convulsions occur. Administration of sodium bicarbonate does not induce attacks as would be expected if the shift of the acid-base equilibrium to the alkaline side were responsible. Wilder's theory that the sedative and anesthetic action of acetone and diacetic acid produces the effect still deserves consideration (1).

The effect in successfully treated cases is a rapid reduction in the number and severity of seizures, especially of the petit mal type, and a marked improvement in irritability, mental condition and general health. The improvement is in proportion to the acidosis. (6) Acidosis is not harmful even when maintained over long periods of time except in cases of diabetes mellitus. The diet can be maintained during the course of infectious diseases such as measles, whooping cough and scarlet fever.

It should be continued four to six months after the seizures have entirely disappeared, after which a normal diet may gradually be substituted. Cases have been reported free from attacks three to four years after resuming a normal diet. (3) In others attacks reappear on any change in diet, and in some the diet must be supplemented by drugs. These cases often cannot be controlled by either diet or drugs alone, but respond to the combination.

The ketogenic diet is calculated to produce a state of detosis in the body similar to that produced by starvation, while providing an

* Read at the Meeting of the Women's Medical Society, held at Syracuse, N. Y., June 1, 1931.

adequate caloric intake for maintenance and growth. Ketosis is recognized by the demonstration of acetone and diacetic acid in the urine, and is produced whenever there is incomplete combustion of fats. In order to oxidize the fatty acids completely to carbon dioxide and water 1 gram of glucose forming elements must be available for 1.5 grams of fatty acid elements in the diet. The glucose forming or antiketogenic elements include all of the carbohydrate and 58% of the protein; therefore the amounts of carbohydrate and protein must be kept much lower than the amount of fat.

The caloric requirement is calculated as 50% above the basal caloric need according to the expected weight for the patient's age and height (7).

The protein requirement is estimated according to the minimal protein requirement as established by workers in diabetic research at 1 gram per kilogram of body weight.

A sudden change from the average diet which is relatively high in carbohydrate to a diet much lower in carbohydrate and higher in fat may cause gastrointestinal disturbances such as nausea and vomiting. Accordingly the change should be made gradually, beginning with a diet in which the relation of the fat to the carbohydrate and protein may be expressed as a ratio of 1:1. (4).

Figuring a diet for a patient weighing 40 kilograms with a caloric requirement of 2400 would be accomplished according to this 1:1 ratio as follows:

Let F = the number of grams of fat; P = the number of grams of protein; C = the number of grams of carbohydrate.

$$\begin{aligned} \text{Let } x &= C+P \\ F:x &= 1:1 \\ F &= x \end{aligned}$$

Each gram of P produces 4 calories
Each gram of C produces 4 calories
Each gram of F produces 9 calories

$$\begin{aligned} \text{Then } 9F+4(C+P) &= 2400 \\ 9F+4x &= 2400 \\ 9x+4x &= 2400 \\ x &= 185 \end{aligned}$$

F=185 grams
P= 40 grams (1 gram per kilogram)
C=145 grams

The ratio is gradually changed from 1F:1C+P to 1.5:1 — 2:1 — 3:1 — 4:1 and sometimes as high as 5:1, changes usually being made once a week until the desired ratio is attained. The optimum ratio for maintaining an effective degree of acidosis is usually 4F:1C+P.

The same diet figured according to a 4:1 ratio would be estimated by similar equations as follows:

$$\begin{aligned} \text{Let } x &= C+P \\ F:x &= 4:1 \\ F &= 4x \\ 9F+4x &= 2400 \\ 9(4x)+4x &= 2400 \\ 36x+4x &= 2400 \\ x &= 60 \end{aligned}$$

F=240 grams
P= 40 grams
C= 20 grams

Acetone and diacetic acid usually appear in the urine after a 2:1 ratio is established and become progressively greater in amount as the higher ratios are attained. Frequent urinalyses should be performed as a check on the maintenance of acidosis. The patient or parents may be taught to perform these tests, which are sometimes a factor in encouraging their cooperation.

It is advisable to hospitalize patients for two or three weeks for instruction in the calculation of the diet and the use of food tables and scales. Patients should be weighed at frequent and regular intervals for a time to detect loss of weight or failure to gain; if this occurs a higher caloric content in the same ratio is indicated.

Some authorities advocate the administration of calcium lactate and brewer's yeast daily to avoid calcium and vitamin deficiencies (1, 3).

In some cases inert material such as washed bran wafers must be added to avoid hunger.

The importance of minor deviations must be impressed upon the patient and his parents. The tendency of children to eat sweets makes this doubly essential. Complete cooperation is vitally important and if it is not obtained no results can be expected.

RECOGNITION OF POLIOMYELITIS

New York State is in the midst of an epidemic of poliomyelitis, whose prevention depends largely on an early diagnosis of every case. The Special Advisory Committee, appointed by the President of the Medical Society of the State of New York, (page 1048) desires to call the attention of doctors to the fact that poliomyelitis may be recognized and diagnosed *before paralysis appears.* The particular symptoms to be looked for in the pre-paralytic stage of the disease are as follows:

1. *Fever.* Never high, with an average of 102° F.

2. *Headache.* Is severe; most frequently general, but may be nuchal and sometimes may be absent, but then replaced by severe back pain.

3. *Rigidity of the Neck.* Distinct resistance to anterior flexion. Rarely is there retraction and never lateral limitation.

4. *Tremor.* Fine trembling of lips and hands, especially on movement as when taking a glass of water. There may be also coarse twitching in sleep.

5. *Apathy.* The patients are mildly indifferent and drowsy—never comatose, and are perfectly bright and alert when aroused, but then are sometimes irritable.

6. *Vomiting.* Once or twice on the first day, but rarely is it persistent or severe. It should be mentioned that vomiting is often severe as an initial symptom in the bulbar types.

7. *Retention of Urine.* When questioned, the mother often remarks a twelve to twenty-four hour period without urination; it never demands catheterization.

8. *Constipation.* It is almost uniformly present.

9. *Sweating.* This is usually seen as beading about the lips and neck, and is rarely profuse.

The pre-paralytic picture presents us a distinct clinical entity with symptoms definitely those of a mild meningitis; headache, tremor, and stiff neck constituting an outstanding triad.

This clinical picture is confirmed by an examination of the spinal fluid.

Every one of these nine symptoms is important, and a determination of its presence or absence in any particular case is extremely desirable. However, a doctor who sees a very few cases is likely to overlook some of the symptoms. An editorial suggestion is that each doctor copy these nine diagnostic points on his prescription pad, and refer to the list when he is confronted with a suspicious case.

CHOOSING A DOCTOR

How to choose a doctor is discussed in the July number of *Minnesota Medicine*, the official organ of the Minnesota State Medical Society.

The discussion was inspired by recent articles in the *Literary Digest* and other popular journals which had asked the question: "If you found yourself ill in a strange town, of whom would you inquire for a good doctor?" Those who answered the question seemed to think of the following groups as the most likely to give wise answers:

1. The semi-religious organizations, such as the Y.M.C.A., the Y.W.C.A. and the Young Men's Hebrew Society.
2. A dinner club, such as the Rotary.
3. A hospital.
4. A welfare organization.

Those who discussed the problem seemed to think that the inquirer might be poorly informed and be referred to a quack; and in that case some of the signs of his recognition are given as follows:

1. He demands pay in advance.
2. He uses only one special system for all complaints.
3. He dispenses only secret remedies.

The Minnesota editor is not satisfied with these signs; and besides the patient cannot apply them until he has called the quack and cannot back out of at least one call.

The question is then asked: "How can a stranger recognize a competent doctor?" The question is very properly left unanswered.

The Minnesota editor then suggests that no one of the newspaper men who tried to give advice on how to choose a doctor had thought of the County Medical Society, insinuating that that organization should be well known, and that it should maintain a central office where inquiries may be made and be given prompt attention. As a matter of fact very few persons could direct an inquirer to an officer of the County Medical Society. Only those societies in large cities maintain offices, and their bureaus of information are very poorly patronized.

If a person is taken sick in a strange town, he will probably be directed to a competent doctor, for anybody to whom he would be likely to apply —a hotel attendant, a clerk in a store, a street-car conductor, a policeman or a druggist—would know a reputable doctor. Practically everybody is honestly desirous of giving aid to a sick person. Certainly one who is sick is not going to go through any extensive mental process to determine whether or not the medical attendant is the best doctor in town.

There is a phase of the question which is practical. Many persons making a home in a strange town soon begin to make inquiries regarding a good doctor to call if sickness should occur. A stranger who is inclined to a particular school, or cult, or method of treatment will seek a practitioner of that persuasion regardless of advice. Strangers in town seem to choose their doctors with wisdom, for the best doctors seem to get the most patients.

THE PUBLIC RELATIONS OF DOCTORS

The methods of treating sickness are the same the world over, for man's physical nature is everywhere the same, and the records of science are free to all who will consult them.

The problems of administrative medicine are also universally the same, for the principles of economics, social influences, and education are as uniform and universal as human nature.

One who reads the journals of the State Medical Societies will find the same problems discussed in all; and prominent among them is the relation of the medical profession to other groups which deal with human health, particularly the State Departments of Health and the voluntary health organizations. This relationship has been assigned by the Medical Society of the State of New York to a standing committee, that on Public Relations, and to a similar committee in every County Society. These committees have been extremely active and have developed working agreements with other health organizations to such an extent that it may be said that the medical profession and the other health organizations have formed a habit of consulting together and of developing unified programs of action. New York State has probably gone farther than any other state in the development of working agreements among the organizations engaged in the promotion of health. Wide publicity has also been given to the activities of the committees on Public Relations, so that every member of the Medical Society of the State of New York is informed of the activities of not only the medical societies, but also of the other health organizations.

The physicians of Michigan have also considered the relations of the physicians to other health organizations, and invited the leaders of the principal official and voluntary health organizations to address the councilors of the State Society at a special meeting, in order to inform the councilors of the activities and aims of the organizations. The medical leaders confessed the need of broader information regarding the other health bodies in order that medical societies should vote their cooperation in all health measures.

A stenographic account of the meeting filled over twenty pages of the July issue of the Journal of the Michigan State Medical Society; and the abstract which is published in this Journal, beginning on page 1056, will be of interest to every practising physician in New York State.

LOOKING BACKWARD

THIS JOURNAL TWENTY-FIVE YEARS AGO.

Fresh Air Treatment of Tuberculosis:—The value of fresh air in the treatment of tuberculosis and other lung diseases was formerly emphasized to such an extent that purity was confused with quantity, as the patients were exposed to extremely cold air in window tents and on open roofs. Concerning the cold air treatment of pneumonia, this Journal of August, 1906, says editorially:

"The desirability of admitting fresh air to patients suffering with pneumonia has been placed upon a scientific footing. It remains for the general practitioner to apply its principles. Its benefits rest not only in the peculiar virtues of fresh air, but in acute pneumonia the breathing of cold air seems of especial value. Northrup, who has studied much and practiced this method of treatment, says, in speaking of branchopneumonia, 'nothing stimulates the heart better than a current of fresh, cool air upon the face. Fresh air stimulates the heart, reddens the blood, quiets restlessness, favors sleep, improves secretions and digestion; in short, meets most of the indications for the treatment of pneumonia in infants.'"

MEDICAL PROGRESS

The Development of the Science of Nutrition in Relation to Disease.—After reviewing the history of nutrition in reference to the proteins, fats, and carbohydrates, and the shifting of interest to the vitamins, J. B. Orr discusses the results of the newer methods of investigation, pointing to the spectacular effects obtained in diseases arising from vitamin deficiency. The work on diseases due to mineral deficiency, which has been done on the large domestic animals, is not so well known to the medical profession. In this work it has been shown that rickets and osteoporosis can be produced by a deficiency of calcium or phosphorus, that a condition characterized by incoordination of movement and later paralysis can be caused by phosphorus deficiency, that goiter can be prevented by the administration of iodine, and anemia by giving iron. A point of practical importance is that when deficiency diseases occur under ordinary conditions the number of animals suffering from minor degrees of deficiency usually far exceeds the number showing gross signs of disease. It has been shown that dietary deficiency increases the susceptibility to infections, that the mineral elements in the diet affect the composition of the blood, the immunological reactions, and the flora of the body. With further work along these lines we shall be able, by dietary measures, to keep animals in such a state of health that when invasion by micro-organisms takes place the *vis medicatrix naturae*—the only therapeutic agent of real value—will be able to exert its full influence, unhampered by abnormal conditions of body fluids due to faulty diet. Recently observations have been made on two tribes in Africa, living under conditions favorable for study. The diet of one tribe consisted chiefly of cereals and was deficient in calcium and vitamins A and D. The diet of the other tribe consisted of meat, milk, and raw blood. In the tribe on the cereal diet pulmonary conditions, bronchitis and pneumonia, accounted for 31 per cent of all cases of sickness, tropical ulcers 36 per cent, and phthisis 6 per cent, compared with a percentage of 4, 3 and 1, respectively, in the tribe on the meat, milk, and raw blood diet. A recent survey in Scotland showed that in a large proportion of families the diet did not supply enough minerals to maintain the maximum rate of growth. The position was worse in the case of iron. We need more information dealing with the amounts of different nutrients required for optimum growth in children and as to the amounts required in dietaries in common use. It has been suggested that diseases such as gastric ulcer, constipation and its sequelæ, rheumatism, anemias, high blood pressure, and cardiac and nephritic disorders, may originate in dietetic errors. Here comprehensive studies are required. — *British Medical Journal*, May 23, 1931, ii, 3672.

Treatment of Gangrene of the Lungs by Emetine.—On the basis of two illustrative cases L. Bouchut shows the remarkable results that can be obtained in gangrene of the lungs by the administration of large doses of emetine from the very beginning and over a long period of time, with no other treatment. He has been giving at the outset large doses frequently repeated, amounting sometimes to as much as 1½ grains, without interruption, and it is to this fact that he attributes the rapidity of cure. Already by the third or fourth day of treatment the patients were considerably improved from both a general and a functional point of view. The first case reported was in a man of 28, ill for a week with fever, cough and fetid expectoration, in whom fluoroscopy revealed a large focus of condensation at the base of the right lung. With a diagnosis of gangrenous pneumonia injections of emetine 0.04 gm. per day were at once begun, and were continued for 12 days, after which the patient had no further symptoms, though a small cavity remained. Two fresh attacks occurred, however, after intervals of a few weeks each. On each occasion injections of 0.08 gm. (1.2 grains) per day overcame the fever in 3 days, and in a few weeks the patient was again symptom free, but still carrying a cavity, though now very small. Should this be slow to close, a phrenicectomy or pneumothorax will be proposed to prevent further recurrence. The second case was in a man of 42 admitted in a state of great prostration after vomiting half a liter of extremely fetid blackish pus, of which he was expectorating an equal amount every day. Fluoroscopy revealed an encysted collection, the size of a mandarin orange, in the right interlobar region, with a fluid surface. Under treatment with emetine 0.08 gm. (1.2 grains) per day improvement at once set in, which continued without interruption. After 1.20 gm. (18 grains) had been given, dosage was reduced to 0.04 gm. (⅔ grain) per day. At the end of a month the patient went to the country for a month. On his return there was perfect anatomic cure and splendid general condition. Here it must be assumed that the cavity was not in the parenchyma but in the interlobar space; hence the case was one of juxta-scissural pulmonary gangrene with encysted interlobar pyopneumothorax, emptied by vomiting and cured by emetine.—*Journal de médecine de Lyon*, June 5, 1931.

Ether as a Cause of Death after Prostate Operations.—The mortality rate in prostate operations has impressed R. J. Minnitt as far too high. For many years he has noticed that patients for whom the prognosis seemed favorable have died from uremic conditions some five or six days after operation, although the preoperative blood urea has been within what are called normal limits. Statistical evidence demonstrates these facts. A hospital report for two separate years shows a death rate of over 50 per cent in two-stage prostatectomies, and almost 50 per cent in one-stage. In all operations undertaken for bladder conditions connected with the prostate the death rate is over 50 per cent. Since it is well known that the effect of ether anesthesia on renal function is considerable, the author has tabulated urea estimations before and after anesthesia, and 24 and 48 hours later. The figures show that no change takes place in the urea during the time of anesthesia, but they suggest two things: (1) the higher the urea content of the patient, the greater is the rise in the day or two following operation; (2) there was no change in the blood urea on the days following the administration of gas and oxygen (one case). The following conclusions are drawn from the investigation: (1) The higher limits of what is called normal blood urea are abnormal. Patients in whom it is high will develop a far higher blood urea after anesthesia. (2) The increase is due to the effect of ether on the renal cells. (3) In any case of enlarged prostate, with a blood urea approaching 40 mg., the operation should be performed in two stages. (4) When there is an abnormal blood urea and any renal damage, gas and oxygen anesthesia only should be used.—*The Lancet,* July 13, 1931, ccxx; 5424.

Influence of Ultraviolet Sunlight and Daylight upon the Thyroid Glands of Rabbits and Cattle.—Gerhard Rosenkranz reports in the *Klinische Wochenschrift* of May 30, 1931, the results of his experiments on rabbits and cattle to determine the effect of ultraviolet light upon the thyroid gland. Three rabbits (referred to for convenience as "light animals") were kept for 8 hours daily for 4 weeks in wire cages on the open balcony of the Davos Institute in full mountain sunlight, returning to their pen at night, while 5 others of the same litter ("dark animals") were kept day and night in the relative darkness of the animal pen lighted only by a small window whose glass was impermeable to ultraviolet rays. All other conditions, such as temperature, moisture, and nutriment were the same for the two lots of animals. At the end of the period all the animals were thyroidectomized and the glands examined. In the "dark" animals changes were found such as are observed in human Basedow's disease: marked hyperemia, both large and small vessels being greatly engorged; follicles very few and very small, with little or no colloid content; conspicuous zones of parenchymatous proliferation were present. The "light" animals exhibited an essentially normal structure of the thyroid gland: follicles of medium size, always very numerous, with little variation in size, always containing colloid; epithelium flat to cubical always one-layered. Even more striking were the results in the cattle experiments, the 10 "dark" animals showing a very high grade increase of thyroid parenchyma, inversely proportional to their age, and very conspicuous in young animals, while the 3 "light" animals which had grazed all day in the pasture exhibited large follicles engorged with colloid, without any suggestion of parenchyma. Sex and sexual maturity played no part, the results being the same in castrated animals. In the cattle the finer details could not be checked up, since it was impossible to obtain specimens in a perfectly fresh condition, but the gross changes were so great that this was of little importance. It must be assumed that the cause of the changes was the lack of ultraviolet rays. This agrees with the extraordinarily important observation that cows which graze on the sunny side of a valley give milk with a higher content of fat than those grazing on the shady side. It also supports Bernhard's finding that goiter is more frequent in villages situated on the shady side of high mountain valleys.

Deformities of the Shoulder in Myopathies.—Henry Meige calls attention in the *Bulletin de l'Académie de Médecine* of June 2, 1931, to a series of deformities of the shoulder which are observable in myopathies when examined from in front. Profile views serve to sharpen or confirm the diagnosis. To recognize these deformities one must recall the normal conformation of the shoulder. The most prominent part of the contour of the deltoid muscle in profile in a person of good muscular development is not at the head of the humerus but much lower down above the deltoid V where the fleshy fibers of the 3 parts of the muscle come together and are superimposed before becoming fixed to their inferior tendon of insertion. But in a subject with a deltoid of mediocre or poor size the point of greatest projection may correspond to the head of the humerus, and frequently a second prominence may be outlined above the insertion into the humerus. This conformation is exaggerated in myopathics. When the arm hangs at the side, the two inflections of the contour are

plainly seen. The upper is rendered the more evident by the fact that the aponeurotic attachments of the deltoid to the clavicle, normally very short, descend much lower; the atrophied fleshy fibers are replaced by thin fibrous tissue, moulded upon the bony head directly under the skin. When the patient is asked to raise his arm, the lower projection becomes exaggerated. The impotence of the elevator muscles of the shoulder, especially the upper third of the trapezius, results in the lowering of the stump. If the atrophy affects the rest of the trapezius as well, and the rhomboid, the shoulder is also carried forward. The chest is then sunken in, especially if the pectoralis major is also atrophied, as is frequently the case. The deltopectoral furrow is scarcely visible in myopathics, being replaced by a rather large flat area. When all the muscles that hold the scapula to the thorax, and especially the serratus magnus, have lost their contractility, the weight of the arm causes the scapula to mount so that even from the front view the latter is outlined by a projection at the base of the neck near the external angle of the supraclavicular triangle. When muscular weakness causes the outer end of the clavicle and the stump of the shoulder to be depressed, the upper margin of the trapezius becomes distended and leaves the midline. As a result the base of the neck appears enlarged and the line to the clavicle droops much more. The supraclavicular triangle becomes a large fossa of which the clavicular margin alone is well demarcated. The mechanism of these deformities is seen clearly if the arms are held forcibly to the sides of the body and the shoulders raised and carried backward simultaneously.

An Analysis of One Hundred Examples of Cardiac Pain in Private Practice.—Louis Faugères Bishop and Louis Faugères Bishop, Jr., state that the chief complaint with which the cardiologist is concerned in private practice is cardiac pain. In order to obtain 100 cases with pain as the presenting symptom 401 cases had to be reviewed, that is, practically 25 per cent of their office patients had this as a primary complaint. The patients were grouped arbitrarily as hypertensive, arteriosclerotic, rheumatic, syphilitic, thyroid, angina pectoris, obesity, effort syndrome. Exertion appeared most frequently as the exciting cause in all groups. Of the entire series 50 per cent gave a family history of cardiovascular disease, nephritis, or diabetes. Of the patients in the angina pectoris and coronary groups 5 per cent were physicians. The incidence of cardiac pain in various occupational groups gives confirmatory evidence of its high frequency among brain workers. There is a slightly higher rate of occurrence among males in the hypertensive group, and a striking predominance of the male sex in the coronary and angina pectoris groups. Exertion appeared most frequently as an exciting cause in all groups. The hypertensive cases showed the highest mortality with no patient symptom-free, and very few classed as improved. While no coronary patient could be classed as symptom-free, the living patients could be grouped as unchanged or improved. Nearly 50 per cent of the angina patients were improved and in addition 4 reported as being symptom-free. In reviewing the electrocardiographic findings it was found that 40 per cent of the angina pectoris groups showed no abnormality. There was a relatively high incidence of ectopic ventricular contractions among the arteriosclerotic patients. More than 33 per cent of the coronary cases showed a negative T wave in the first lead, and none in the group could be classified as showing "normal mechanism." In the fatal cases serious changes in the graphic records were observed in all groups, with the exception of the angina pectoris class, where 2 out of 4 patients showed no abnormality of a grave nature.—*American Journal of the Medical Sciences*, July, 1931, clxxxii, 1.

Cure of Intracranial Hypertension in a Case of Cerebral Tumor.—Intracranial hypertension, says Egaz Moniz, writing in the *Journal de Médecine de Lyon* of May 5, 1931, is not a direct consequence of the cerebral tumor. There are large tumors which continue to develop until the patient dies, without provoking hypertension. On the other hand, small tumors may be accompanied at a given moment by the syndrome of hypertension. Moniz thinks that under certain conditions the tumors cause circulatory troubles that are followed by cerebral edema, the initial phase of an inflammatory condition of the leptomeninges, which is always the pathologic-anatomic base of intracranial hypertension. Thus the pathogenesis would be the same in serous meningitis and in cerebral tumors. If the hypertension were due only to increase in size of the neoplastic mass, it would never disappear without the latter having disappeared. But it is known that intracarotid injections of 25 per cent sodium iodide cause the syndrome of hypertension to disappear even in cases of cerebral tumor. While such results do not often last more than a few weeks, there are some cases, such as the one here reported, in which the patient's improvement has persisted despite the fatal progress of the tumor. The author's case, verified at autopsy, was one of a tumor of the septum lucidum, the third ven-

tricle and the lateral ventricle in a girl of 17. Within a single month severe headaches in the frontal region, vomiting, diplopia and partial loss of visual acuity had all supervened. Right and left encephalograms were made at an interval of 11 days, the patient having been prepared by luminal. Two days after the second injection the headaches disappeared, vision improved and was nearly normal two months later. The patient considered herself cured and resumed her work. A single crisis of headache 6 months later and one more on the day of her death, again 6 months later, were the sole indications of any further disturbance. Yet the autopsy revealed the presence of a large, inoperable cerebral tumor—a small-cell glioma. The improvement in the patient seemed to justify the diagnosis of serous meningitis, although the arteriogram might have been interpreted as a tumor of the third ventricle. The case is of interest because the cure of the intracranial hypertension was as complete, at least for 8 months, as if a decompressive operation had been done. Yet all this time the tumor was gaining extraordinarily in size, without neurological or focal symptoms.

The Common Causes of Earache.—The causes of earache are classified by G. Edward Tremble as intrinsic and extrinsic. By intrinsic causes are meant organic lesions within the external auditory canal, middle ear, or mastoid cells, giving rise to pain. These causes include foreign bodies, cerumen, furuncle, herpes zoster, otomycosis, acute otitis media, chronic otitis media, and mastoiditis. The condition can usually be seen at once by means of the aural speculum or otoscope. A mistake is often made in distinguishing between furuncle in the posterior segment of the canal and mastoiditis; this error may lead to an unnecessary operation. In differentiating these conditions, it is well to remember that pressure over the mastoid does not increase the pain due to furuncle, but if there is inflammation in the mastoid process marked tenderness is present. If the cartilaginous portion is affected by boils, movement of the mandible, as in chewing or yawning, usually accentuates the pain, and passive movement of the auricle also aggravates it. In children an annoying type of earache occurs, in which very often little or nothing can be seen by means of the aural speculum. Almost invariably it signifies a mild infection at the entrance and along the Eustachian tube. Examination frequently reveals an enlarged adenoid or slight inflammation of the nasopharynx. Extrinsic causes of earache are those which produce pain in the ear reflexly by lesions remote from the ear itself. The drum in these cases shows little or nothing, often a normal picture. In order to understand the mechanism and interpret the significance of referred pain, it is not only necessary to know the nerve supply of the ear, but also to what other organs the same or very closely related nerves are distributed. Tremble gives a description of the innervation of the ear and an interesting diagram showing these nerve connections. The most frequent cause of reflex otalgia is of dental origin. Other causes are affections of the pharynx, larynx, tonsils, side of the tongue, particularly the anterior two-thirds, inflammatory conditions of the salivary glands, upper part of the trachea, and rarely the lymph glands of the neck, goiter, and caries of the cervical vertebrae.—*Canadian Medical Association Journal,* June, 1931, xxiv, 6.

Ethyl-Iodide in Ear, Nose, and Throat.—Joseph Prenn bases the treatment he describes on the well-known predilection of iodine for inflammatory exudate and diseased cells. Its action is due not to antisepsis, but "to its ability to destroy the antitryptic power in the blood and allow the proteolytic ferments to dissolve any degeneraed or necrotic tissue." It stimulates leucocytosis, both local and general. It would appear that there is a broad field for iodine in certain diseases of the ear, nose, throat, and bronchial tree. But iodine, as such, is an irritant to the mucous membrane, and even in its dilute form it cannot be applied to some of the inaccessible parts without instrumentation. In the volatile ethyl-iodide, the apparatus and method for the use of which have been described in the *New England Journal of Medicine,* 202:1156, June 12, 1930, we have an iodine preparation in evanescent state which can be used to good advantage. Breathing the ethyl-iodide through the mouth and exhaling it through the nostrils effects a general diffused application of iodine to the mucosa of the entire tract through which the air courses. The air ordinarily passes through the Eustachian tube with each inspiration and expiration. After the patient has received one or more treatments in the office, he can employ the method at home. The author cities cases showing the apparently beneficial action of ethyl-iodide and the changes in the pathology of the mucous membrane that follow its use. Several patients who, in addition to catheterization of the eustachian tubes and mobilization of the drum membranes, received these inhalations, followed by the Valsavian method, have reported improvement. The results have also been satisfactory in a case of tracheitis.—*New England Journal of Medicine,* May 21, 1931, cciv, 21.

LEGAL

CORPORATE DIRECTORS

II

By LORENZ BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

In a previous article appearing in these columns we outlined a few of the legal consequences of inactivity on the part of men chosen to serve as corporate directors, and attempted to show that "the duty of a director is to direct." In this editorial we shall consider some of the affirmative acts on the part of a director for which he may be held legally accountable.

It is fundamental that the general rules by which a director must govern his conduct are the rules of fair and honest dealing. A directorship is a position of trust, and the duty of a director is to look after the interests of minority stockholders as well as the interest of those in control of the majority of voting power. Some years ago in a case where it was charged that directors were attempting to dissolve a prosperous corporation so as to injure the minority stockholders, our Court of Appeals was asked to rule as to what charges would be sufficient to warrant the intervention of a court of equity. In its opinion the Court stated:

"The prerogatives and functions of the directors of a private business corporation are sufficiently defined and established. The affairs of the corporation shall be managed by its board of directors. The relation of the directors to the stockholders is essentially that of trustee and cestui que trust. The directors are bound by all those rules of conscientious fairness, morality and honesty in purpose, which the law imposes as the guides for those who are under the fiduciary obligations and responsibilities. They are held, in official action, to the extreme measure of candor, unselfishness and good faith. Those principles are rigid, essential and salutary. * * *

"The directors, generally speaking, are the exclusive executive representatives of the corporation and are charged with the administration of its internal affairs and the management and use of its assets. The ordinary trust relation of the directors to the corporation and stockholders is not a matter of statutory law, or of technical law. It springs from the fact that the directors have the control and guidance of the corporate business, affairs and property, and, hence, of the property interests of the stockholders. Equity, at least, recognizes the truth that the stockholders are the proprietors of the corporate interests and are ultimately the only beneficiaries thereof. Those interests are, in virtue of the law, intrusted, through the corporation, to the directors and from that condition arises the trusteeship of the directors with the concommitant fiduciary obligations. * * *

"A court of equity will protect a minority stockholder against the acts or threatened acts of the board of directors or of the managing stockholders of the corporation, which violate the fiduciary relation and are directly injurious to the stockholders."

On many occasions a director will find himself able, by reason of his advantageous position and peculiar insight into the corporate affairs, to use the power so acquired to make financial gain for himself, but upon such conduct our Courts have placed unqualified disapproval. For instance, the directors cannot validly vote themselves bonuses, increases in salary or special allowances. If a director renders a service to the corporation apart from his duties as such, he cannot take part in a vote awarding himself an excessive compensation for those services. The directors may not issue stock to themselves where they do not pay full value for it, or even for full value paid if it appears that by so doing they are changing themselves from minority to majority stockholders. If a corporation is insolvent, a director may not vote the payment of a debt owed him so as to prefer his claim to the claims of other creditors. An excellent general statement of the controlling principle here involved was set forth recently as follows by our Court of Appeals:

"The individual defendants, as directors, occupied the relation of trustees to the corporation and its stockholders, and the obligations of this trusteeship are the basis of ascertaining whether or not their acts, as alleged, were fraudulent. They were the exclusive executive representatives of the corporation and were charged with the administration of its internal affairs and the management and use of its assets. Their corporate acts, within the powers of the corporation, in the lawful and legitimate furtherance of its purposes, in good faith and the exercise of an honest judgment, are valid and conclude the corporation and the stockholders. Questions of policy of management, expediency of contracts or action, adequacy of consideration, lawful appropriation of corporate funds to advance corporate interests, are left solely to their honest and unselfish decision, for

their powers therein are without limitation and free from restraint, and the exercise of them for the common and general interests of the corporation may not be questioned, although the results show that what they did was unwise or inexpedient. It is, however, the inflexible rule that they cannot exercise the corporate powers for their private or personal advantage or gain. The law stringently and rigorously forbids to them the use or disposition of the funds or assets of the corporation for their individual enterprises or acquisition, and for any misfeasance or breach of duty or trust resulting in damage to the corporation they are subject to be called to account by the corporation in the appropriate action. These principles, based upon a sound public policy and morality, are so firmly fixed in our jurisprudence that they are not open to discussion and so familiar that authorities declaring them need not be cited."

Likewise the Courts have often intervened and compelled directors to surrender to the corporation secret gains obtained by them as commissions received from persons with whom the company is dealing, or to account where the conduct of the director is influenced by the payment of a gratuity or personal consideration. It is similarly improper for a director, upon learning that the company intends to acquire certain property, to buy the property in question himself and then to sell or lease it to the company at a profit.

Another possible source of liability on the part of directors is found where they take action resulting in a dividend being improperly paid. Directors have been found to have backed the declaration of dividends that impaired the capital of the company. Such action, of course, is improper and may give rise to a suit to recover the amount so paid from the directors.

In addition to civil liability for affirmative acts of misconduct, a director is also open to criminal prosecution for violation of our penal statutes. Of course the general penal statutes governing misconduct apply to them in the same degree as to other individuals. Frequently we find directors charged with embezzlement, larceny and the like. But, in addition, certain crimes grow out of their wrongful action in office for which the law makes special provision. A corporation is a creation dependent for its very existence upon the grant of a privilege by the State, and the State in turn demands compliance with many statutory standards. For example, the statutes make it a crime for a director to make false book entries or to refuse to permit lawful inspection of the corporate books or to fail to make reports required by law. The law is very specific in listing various fraudulent acts which are punishable criminally, such as the improper issuance of stocks and bonds and the improper use of the corporate assets. To illustrate to what extent these criminal statutes go, it may be noted that in this State it has been made a crime for a director to sell or agree to sell stock of the corporation of which he is a director, unless at the time of such sale or agreement he is the actual owner of the stock; that is, he may not sell stock in his own corporation "short."

In conclusion it should be stated that no attempt has been made to make this article or the preceding one a complete and comprehensive treatment of the law governing corporate directors, for to do so would of necessity require a discussion that would fill a large volume. Our purpose has merely been to set out a few of the factors which a man should bear in mind when he considers accepting the duties of a place of the board of directors of a corporation. In the final analysis, honesty, diligence, good faith and fair dealing are the standards of conduct imposed by law upon directors. The statutes and rules of law are designed for the purpose of enforcing these standards of conduct.

CLAIMED NEGLIGENT PRESCRIPTION OF ERGOAPIOL

The doctor in this case was called to the home of a patient whom he found in bed complaining of vaginal bleeding and pain. He examined her and found her to be suffering from a uterine fibroid about the size of a fist, which was accompanied by bleeding. He prescribed ergot and hydrastis by mouth and gave instructions about taking it. He called the following day and found the woman about the same. The doctor then decided to change the medicine and prescribed ergoapiol, to be taken one teaspoonful three times a day. The next day he observed that the bleeding had not completely subsided and gave her a hypodermic injection of pituitrin. The bleeding stopped promptly in response to that treatment. The doctor did not call to attend her further but suggested *x*-ray treatment to dissipate the fibroid tumor and referred her to another doctor, who specialized in *x*-ray therapy, for the purpose of such teatment. The doctor was informed that the woman never consulted the *x*-ray specialist for treatments.

Shortly thereafter a malpractice action was started against the defendant doctor by the patient. The plaintiff's complaint alleged that the bleeding with respect to which the doctor treated her was due to menopause, and that the doctor was negligent in failing to ascertain that her condition

was caused by menopause, and in prescribing excessive and injurious doses of ergoapiol.

The complaint further charged that as a result of said negligence the plaintiff's health was greatly injured and she was caused to suffer great pain.

The action was duly brought on and when the case was called on the calendar for trial the plaintiff and her attorney failed to appear. On motion of the attorney for the doctor the plaintiff's complaint was dismissed. Judgment entered for the defendant and the case was concluded in his favor.

CLAIMED NEGLIGENT TREATMENT OF CUT

In this case the plaintiff consulted the defendant doctor, giving a history of having received an injury caused by being hit with a milk bottle which had been hurled through the winlow of a railroad car on which he was riding.

Upon examination the doctor found multiple small wounds on the man's neck and a deep one-half-inch incised wound on the dorsal surface of the right thumb. The extensor tendon was exposed but while the cut affected the tendon it was not completely severed. The doctor placed mercurochrome on the wound and approximated the edges with a strip of adhesive tape and applied a dry sterile dressing. On four subsequent occasions the man returned and the doctor dressed the hand. On one of said subsequent days the doctor discovered that the remaining fibres of the extensor tendon had become separated and that the patient had lost the power of extending the distal phalanx. The doctor advised the patient that in order to properly effect a cure, he would have to suture the tendon. The plaintiff informed the doctor that he intended leaving for Europe in a short time and would prefer not to have the tendon sutured at that time. The doctor advised the patient that there was no occasion for haste and that it could be done later. This satisfied the patient and when the doctor last examined him the wound was almost completely healed and the thumb normal except for the divided tendon which made itself evident by the loss of the power of extension.

The doctor heard no more of the case until a summons was served upon him in an attempt to recover large damages for alleged malpractice. The action was duly noticed for trial but before the same was reached in its order on the Calendar, the defendant died and the action was abated.

FAILURE TO DETECT FRACTURE AND DISLOCATION

The plaintiff in this case while being attended in the Turkish baths of a hotel apparently was taken with some sort of an epileptic fit. The employees of the hotel attempted to remove the plaintiff from the room in order that he be revived, and in so doing permitted him to fall on the floor, injuring his right shoulder. He was taken upstairs to his room in the hotel and a doctor was called in promptly to attend him.

When the doctor arrived the man had regained his senses and stated that while he had been sitting on a chair in the Turkish baths he was taken with a sudden pain in the shoulder and had no recollection from that time on. The doctor examined him and prescribed salicylate tablets and left instructions that the patient should call him if he needed a doctor again. The following afternoon the patient attempted to call the said doctor, but by reason of the fact that he was operating at a hospital a second doctor was sent to make the call in his place. The second doctor found the patient in bed complaining of a pain in the right shoulder. He examined the patient's general condition but not for a fracture or dislocation. Upon being informed that the patient was taking salicylate tablets he directed the patient to continue taking such medicine.

This second doctor returned the following day and found the patient still in bed with marked ecchymosis on the right shoulder. The doctor then became suspicious of dislocation and directed the patient to dress and go to a hospital for an *x*-ray picture. The patient had *x*-ray pictures taken which disclosed a dislocation of the shoulder and a fracture of the tuberosity of the right humerus. A surgeon was then called in who reduced and cared for the dislocation and fracture.

An action was instituted against the hotel and the first two doctors who attended the patient, in which the plaintiff alleged that the hotel was negligent in permitting the plaintiff to sustain injuries, and that the defendant doctors were guilty of malpractice in their wrongful diagnoses of the said injuries, and that as a result of the improper treatment rendered to the patient by the said doctors great injuries and much disability were caused.

When the action was about to be reached for trial, the hotel company settled the action insofar as it was concerned. Through the efforts of your counsel the action was discontinued against the two doctors, thereby terminating the matter in their favor without trial and the prolonged annoyance of litigation.

NEWS NOTES

INFANTILE PARALYSIS COMMITTEE

A sub-committee on Infantile Paralysis was appointed by the President of the Medical Society of the State of New York, to cooperate with Dr. T. P. Farmer, chairman of the Committee on Public Health, in devising ways by which family doctors may do their part in the prevention and control of the epidemic which is now prevalent. The new committee consists of the following physicians: Dr. Charles Hendee Smith, New York City; Dr. Walter D. Ludlum, Brooklyn; Dr. John A. Card, Poughkeepsie; Dr. Henry L. K. Shaw, Albany; Dr. Wardner D. Ayer, Syracuse; Dr. Stanhope Bayne-Jones, Rochester; and Dr. Clayton W. Greene, Buffalo.

The committee met with State Commissioner of Health, Dr. Thomas Parran, on Friday, August 7, in the Albany offices of the State Medical Society. The number of poliomyelitis up-State cases reported from July first up to the time of the meeting was 104, distributed as follows:

Nassau County	21	Orange, Schenectady,
Westchester	20	Rensselaer and Wash-
Columbia	10	ington, 12 each.
Albany	8	Rockland, Cattaragus,
Suffolk	8	Niagara, Broome,
Sullivan	4	Delaware, Oneida,
Ulster	4	Otsego, Essex,
Erie	3	Dutchess, Putnam and Onandaga, 1 each.

The number of poliomyelitis cases reported in Greater New York since July first is 1212.

While these figures are small compared with those of the great epidemic of 1916, yet they indicate a grave menace which the physicians of the State are preparing to meet.

The sub-committee made the following recommendations regarding the use of immune serum:

"That the use of serum of recovered cases in the treatment of pre-paralytic cases is highly desirable; that all possible aid should be given to the State Department of Health in the collection of an adequate amount of such serum; that to make the most efficient use of serum to the largest number of cases, control of the use of the serum is highly desirable."

The sub-committee also approved the attitude of the State Department of Health and appealed to the County Medical Societies to take organized means to combat the epidemic in their own counties. The statement authorized by the sub-committee was as follows:

"The committee commends the efforts of the State Health Department to make available to the physicians assistance in laboratory diagnosis at the bedside of suspected cases in the pre-paralytic stage, and urges all physicians to avail themselves of these facilities.

"The committee believes that such diagnostic service should be organized in all sections of the State; and that the State should appoint qualified local representatives in any community in which the disease appears, and, where necessary, should assign its own staff members to assist in making the diagnosis and to be responsible for the distribution of serum; and that cities with a population of 50,000 or over be requested to organize diagnostic service for their own localities.

"The committee urged that in counties where an outbreak of the disease seems impending, county medical societies immediately arrange a meeting for the discussion of the disease, and that all physicians, whether members of the county society or not, be invited to these meetings." (See page 1038.)

NASSAU COUNTY POLIOMYELITIS

The Medical Society of Nassau County held a special meeting on August fifth for the purpose of hearing the subject of poliomyelitis presented by Dr. Lloyd Aycock of Boston, Director of the Harvard Infantile Paralysis Commission, who had been secured as speaker through the cooperation of the Medical Society of the State of New York and the Health Department. About 125 members were present.

Dr. Aycock reviewed the development of our present knowledge concerning the epidemiology of the disease, and stressed the importance of the discovery that we can transmit the virus of poliomyelitis to monkeys. It has been shown

definitely that one attack of poliomyelitis in such monkeys confers a permanent immunity; and serum from them will neutralize the virus in a test tube. After testing the serum of human adults, it was found that ninety per cent of them could neutralize the virus in vitro even as that of the inoculated monkeys. It leads to the conclusion that ninety per cent of the populace has at some time been infected with the virus of poliomyelitis. It must be relatively frequent to find exposure resulting in sub-clinical immunization, and so the problem of checking the organism is almost futile.

Dr. Aycock stated that inasmuch as the chance of exposure during the epidemic is manifold and one can not determine in whom or where the danger lies, he advised parents to confine their children's activities to playing in very small groups of carefully chosen playmates.

One can vaccinate with the virus and secure an active immunity; but since a very small fraction of the children are destined to become paralyzed, it is impossible to determine whom to vaccinate. Passive immunity may be secured through the administration of serum from a convalescent case, but again objections are strong. Since such immunity lasts but 10 days, and the quarantine period of poliomyelitis is 21 days, one could not choose the exactly proper time to give the serum prophylactically.

Dr. Aycock advocated immunization of the remainder of a family in cases where poliomyelitis is discovered in a member early; but he was not willing to sponsor promiscuous vaccination.

One point which he stressed was the importance of history, in the light of present day knowledge. Unlike the old text-book description which said that the child went to bed well and woke up in the morning paralyzed, one is now able to dig out a history of milk fever, headache, and vomiting about five days before. This is the advice which one can tell to anxious mother: "In the presence of this epidemic, don't delay calling a doctor when the child presents a headache, or fever or vomiting whether there be apparent reasons for these symptoms or not."

A typical history would be that of a well-developed boy of 5 years who is exposed to poliomyelitis. He goes blithely along for about ten days (7 to 14 days) without complaining. On the tenth day he eats a smaller breakfast than usual but attends school. He is excused from school in the middle of the morning because of a headache, and chooses to remain on a bed when he arrives home. Attempts to eat lunch result in vomiting. Perhaps he is given a physic and promptly vomits this, causing the comment to be made that the physic is the probable cause of the vomiting. Then if he belongs to the eighty-five per cent of the cases who have a staggering course of mild fever and restlessness, he drags on till the fifth day when he has any or all of the following symptoms and signs: Course tremors, shudders, stiff neck (which can be demonstrated to be voluntary), apprehensiveness which is possibly due to some effect on the thalamus as in rabies. When the patient is asked to sit up, he climbs up with the aid of his arms; and when asked to flex the chin on the chest, he bends forward from the hips and drops his chin by opening his mouth, and it is obvious that he is favoring his back and neck. The symptom of "tenderness along the spine" which is described in old texts is an error of observation.

If the patient belongs to the fifteen per cent who have a mild upset on about the tenth day after exposure, but then have five days of apparent freedom from any complaints, he will probably have headache, fever, and vomiting again on the fifteenth day after exposure, plus some nervous symptoms as described before. He then fits Draper's so-called "Dromedary Type," due to the two humps in his symptomatic course. The paralysis will follow within about three days.

Spinal puncture clinches the diagnosis if the cell count is elevated, generally running between 100 and 200; and if the globulin is increased. Draining away spinal fluid is a beneficial procedure. The intraspinal administration of 15 cc. of immune serum from a convalescent case is good practice in pre-paralytic cases; and the intravenous injection of 30 to 45 cc. is recommended.

Dr. Benjamin R. Allison, President of the Society, announced that the Society had taken steps to cooperate with the State Department of Health in whatever measures might be necessary to prevent or control the epidemic.

Dr. M. D. Dickinson, District State Health officer, described the cases that had been reported, and announced the formation of a field laboratory unit to function in the homes where the diagnosis is obscure. The personnel at this date consists of Dr. Dickinson himself and Dr. D. Edward Overton. The unit is ready to do lumbar punctures, spinal fluid cell counts, and globulin tests, and to administer immune serum both intraspinally and intravenously in the homes. Dr. Overton is also collecting immune serum from recent poliomyelitis cases throughout Nassau County under the direction of Dr. Dickinson, for use by the New York State Department of Health.

After the meeting Dr. Allison issued a news release story giving popular advice regarding the nature and prevention of poliomyelitis, and urging the prompt calling of a doctor.

MEDICAL WARES

VITAMIN D BREAD

The story of vitamin D bread begins with the four principal vitamins whose sources of action are well known. An abundance of the vitamins A, B, and C are contained in common foods, and will usually be taken in sufficient amounts when one's bill of fare is as varied as that of ordinary menus of homes and restaurants; but vitamin D, the antirachitic, is found in only a few natural foods; and in them it exists in only small amounts. It is abundant in cod liver oil, but no one uses that as a food. Some vitamin D is found in egg yolk, a lesser amount in butter, and still less in whole milk. These are almost the only common foods that have vitamin D, and they do not usually contain enough to maintain the body in the best condition of health.

The body under natural living conditions does not take its main supply of vitamin D ready-made in its food; but in the form of ergosterol which is a normal constituent of yeast and other foods. When the ergosterol is absorbed and is carried to the skin, it is activated by sunlight so that it becomes vitamin D. Ergosterol does not become vitamin D in the absence of sunlight, nor does sunlight cure rickets if the body does not contain ergosterol on which the rays can act.

Ergosterol can be isolated in a chemically pure state in the form of short needle-like crystals. When it is irradiated with ultraviolet light, it becomes vitamin D in a stable form. The irradiated ergosterol, when dissolved in corn oil, is known by the trade name *Viosterol,* and is adjusted to a standard strength measured in vitamin D units.

The most evident effect of vitamin D is to promote the utilization of calcium by the body. If vitamin D is absent from the food of a growing child, calcium is not deposited in the bones, and rickets develops. Young white rats are the principal animals used in experimental rickets because of the rapidity and certainty of the results, and the ease of recognizing the condition. When a growing white rat is placed on a diet which contains no vitamin D for 21 days, the epiphysis of the distal end of the radius consists of uncalcified cartilage, as shown by the *x*-ray; but when vitamin D is added to the food, calcium is quickly deposited, and the first evident effect is the appearance of a line of calcification in the cartilage.

One unit of vitamin D is the total amount which, when fed to a rachitic white rat, will induce the formation of a continuous line of calcification within ten days.

Standard cod liver oil contains 47 units of vitamin D in each teaspoonful.

Standard viosterol contains 3,333 units in each gram.

The amount of vitamin D required to prevent rickets in the average growing baby is 140 units daily.

A leader of research in vitamin D is Professor Henry Steenbock, of the University of Wisconsin, who was granted a patent, number 1,680,818, for the manufacture of irradiated ergosterol. Professor Steenbock immediately assigned the patent to the Wisconsin Alumni Research Foundation.

The University of Toronto also promoted researches into vitamin D and other biological products through its Pediatric Research Foundation under the direction of Dr. Frederick F. Tisdall. Since the two universities were working along the same lines, they cooperated in developing the means of supplying vitamin D to people generally, and decided that the most practical method was by means of bread. The two universities therefore made a contract with the General Baking Company that the Company should have the exclusive right to add vitamin D to its bread, subject to the tests and control of the University of Toronto, in the same manner that the University controls the standardization of insulin. All the royalties under the contract are devoted to making tests of the bread bought in the open market and in further research. Moreover, a provision of the contract obligates the General Baking Company to issue permits to other companies to use the process, in the expectation that in the near future all baking companies will adopt the plan of adding vitamin D to their products so that everybody can get a normal supply of vitamin D anywhere in the United States, and at no extra cost.

The amount of vitamin D which is added to the bread was set at 140 units in each loaf of twenty-four ounces. This is equivalent to three teaspoonfuls of standard cod liver oil,—an amount which would give an unpleasant taste to the loaf if it were used.

The General Baking Company is not permitted to charge an extra price for its vitamin D bread; it profits by the satisfaction and reputation of supplying the people with a food element which is of great importance to their health and vigor.

THE DAILY PRESS

HE DIDN'T KNOW IT WAS LOADED

The plate for this cartoon was made a year ago, but we have delayed using it because of an inferiority complex induced by a critic's remark that he did not believe in pictures or stories that had a moral attached to them. We first thought we would use the cartoon to call attention to Fourth of July dangers, and then we thought of the warning issued by the Commissioner of Health against bathing in polluted water. Then, too, there is the ever-present menace of the reckless drivers of automobiles, and in the Fall there will be a toll of lives of careless hunters. We will not attach any moral at all to the cartoon, for its lesson is plain and can be adapted to any subject under the heavens. It may be a source of inspiration to physicians who will become engaged in popular medical publicity when the plans of the Medical Society of the State of New York are developed to the extent that they are in Indiana, Illinois, and some other Western States.

We wonder how many of the readers of this JOURNAL take its cartoons as seriously as do the editors, whose intention is to tell a health story with a simple picture, and in a kindly way. But after all nothing can take the place of close application of the mind to a problem. A child learns the multiplication table by hard work, unrelieved by pleasant pictures and experiences. An adult learns the rules of health because of his hard experience after he has broken them.

From the New York Herald Tribune, August 1, 1930.

MAIL ORDER EYE GLASSES

The Department of Health of New York City has issued public warnings against vendors of eye glasses and dealers who pretend to fit persons by mail. The New York *Herald Tribune* of July 20, says:

"The National Better Business Bureau investigated the mail order eye-glass business, and speaking of its report Dr. Shirley W. Wynne, Health Commissioner, hits at the fakers who send various devices for the individual to test his own sight, and adds that because of the cheapness of the manufacture of such devices 'they cannot be mathematically correct.'

"About the persons involved in the mail order eye-glass business, Dr. Wynne said: 'In the course of our investigation we found that several of the fakers who were using the title "doctor" in their advertising and literature, were not doctors at all; that the majority of them knew little or nothing regarding refraction, and that none of them had the slightest knowledge of the human eye or its ailments. Some of this gentry have branched out into the spectacle trade after failing in the jewelry line, others have gone into the eye-glass business because of the money they saw in it'."

ANNALS OF THE PICKETT-THOMSON RESEARCH LABORATORY. Vol. VI, The Pathogenic Streptococci: the role of the streptococci in scarlet fever. Quarto of 470 pages. Baltimore, The Williams and Wilkins Company, 1930.

This large volume contains a very excellent and much needed compilation of the literature on the subject of scarlet fever, particularly as to the part played by the streptococcus in the causation of the disease.

The increase in the research work on the etiology of scarlet fever has been tremendous in recent years, due, in large part no doubt, to the discovery of the Dicks. This volume, so far as we know, is the most complete summary of the literature bearing on the subject and its correlated topics which has appeared up to this time. To place within the covers of one volume reference to and often detailed abstracts from some 1400 research papers, is no small task, and the authors deserve an abundance of praise for the careful and painstaking manner in which the entire book has been prepared. The publication provides a medium which will no doubt greatly assist in disseminating more generally among the profession the information accumulated to date as to the specific relation of the streptococcus scarlatenæ to scarlet fever.

JOSEPH C. REGAN.

A TEXT-BOOK OF THE SURGICAL DYSPEPSIAS. By A. J. WALTON, M.S., M.B. Second Edition. Octavo of 720 pages, illustrated. New York, Longmans, Green & Company, 1930. Cloth, $15.00.

The first edition of this book appeared in 1923. In the seven years elapsing since then so much work has been done in upper abdominal surgery that the Author's task has not been an easy one. New sections devoted to inflammatory lesions of the stomach other than ulcers, to congenital cysts of the bile ducts and to cholecystography have been added. The chapters dealing with the causes of ulceration of the stomach, the choice of treatment of gastric ulceration, duodenal diverticula, ileus and fistulæ, gastro-jejunal ulceration and the operative technic of gastric lesions have been almost entirely rewritten. The author has, however, curtailed several portions, particularly that devoted to the surgical methods of treating visceroptosis so that the work as a whole is not enlarged. The statistics throughout have been revised, the number of illustrations have been increased. Several of the older diagrams have been revised.

The author has brought the book up-to-date and has made a rather complete and compact résumé of the subject, particularly when one considers that the volume deals with such a large number of lesions, including gastric ulcers; inflammatory lesions of the stomach other than ulcer; duodenal ulcers and diverticula; pyloric and duodenal obstructions; gastric neoplasms; foreign bodies and injuries of the stomach and duodenum; acute dilatation; volvulus and intussusception; gall stones and their complications; the diseases of the pancreas, visceroptosis and appendix dyspepsia, with the etiology, pathology, symptomatology, treatment, operative technic and choice of operation. It really is a great deal to cover in a book of this size. However, the author has made interesting reading of it. His own large experience makes his conclusions particularly valuable, and there is appended to each chapter a number of references particularly to English and American authors.

RUSSELL S. FOWLER.

HANDBOOK OF DISEASES OF INFANTS AND CHILDREN for students and practitioners. By F. M. B. ALLEN, M.D., M.R.C.P. Octavo of 595 pages. New York, William Wood & Company, 1930. Cloth, $5.00.

In his preface the author says: "I have avoided theories as far as is compatible with an intelligent understanding of the subject."

He has very ably carried out the intention so expressed, and given us a brief outline of each subject which is well expressed, definite and to the point.

He stresses the importance of breast feeding in accordance with the modern American trend, and covers briefly and well the vast domain of artificial feeding, and this part of the book is unusually free from individual bias.

A useful list of prescriptions for infants and children is part of the appendix.

This book is a sound, reliable guide, giving the foundations for further study. It deserves a place on the library shelves of the physician interested in infants and children, and is well adapted to quick reference.

ARCHIBALD D. SMITH.

PYE'S SURGICAL HANDICRAFT: A Manual of surgical manipulations, minor surgery, and other matters connected with the work of house surgeons and surgical dressers. Edited by H. W. CARSON, F.R.C.S. Tenth edition. Octavo of 641 pages, illustrated. New York, William Wood & Company, 1931. Cloth, $7.00.

This edition is a revision of a popular English work on Minor Surgery, which first appeared over the name of Walter Pye in September, 1884. The present volume of 640 pages, with 343 illustrations and 22 plates is of convenient size for ready reference and easy reading.

In this book, it has been the aim of the author to describe the details of surgical work as it appears from the point of view of house surgeons and dressers in surgical wards. With the constant revisions and additions of the various editions, the work has an added appeal even to those who have finished their interneships and have continued their interest in the problems of so-called, minor surgery. If one includes the chapter on Splints, over 110 pages are devoted to a consideration of the treatment of Fractures, Dislocations and Sprains. Even so considerable a portion of a book, we do not feel, however, is used unwisely in the discussion of so important a subject as the treatment of fractures.

J. RAPHAEL.

INTRODUCTION TO MEDICAL BIOMETRY AND STATISTICS. By RAYMOND PEARL. 2nd rev. edition. Octavo of 459 pages, illustrated. Philadelphia & London, W. B. Saunders Company, 1930. Cloth, $5.50.

The authors are unduly modest in describing this work as an "introduction." The book contains an extensive study of the elements of statistical methods useful in the biostatistical and medical fields. All that should be done to figures between their first selection for statistical treatment and their final presentation in sppport of the argument or theory for which they are required is treated in a very complete manner.

All points dealt with are well illustrated by numerous tables, charts and graphs, and a satisfactory index is provided.

G. HOLBROOK BARBER.

LOVETT'S LATERAL CURVATURE OF THE SPINE AND ROUND SHOULDERS. Fifth edition revised and edited by FRANK R. OBER, M.D., and A. H. BREWSTER, M.D. Octavo of 240 pages, illustrated. Philadelphia, P. Blakiston's Son & Co., Inc., 1931. Cloth, $3.50.

We are indebted to Dr. Ober and Dr. Brewster for carrying on the popular work of the late Dr. Lovett on curvature of the spine. Through the efforts of these gentlemen we now have the fifth edition of this concise and definite work. Little need be said of the original work but in this edition the work of Galeazzi is given in detail and furthermore the chapter on corrective exercises has been rewritten.

We trust that the editors will continue to carry on this contribution of Dr. Lovett to scoliosis.

JA. C. R.

A Handbook for Senior Nurses and Midwives. By J. K. Watson, M.D. Second edition. 12mo of 676 pages, illustrated. New York and London, Oxford University Press, 1931. Cloth, $4.00. (Oxford Medical Publications.)

As the title indicates, the author intends his book for the use of senior nurses and midwives, and he expects it to be used in conjunction with his volume, Handbook for Nurses. In this second edition, the text has been carefully revised, and several new chapters have been added. The book is not, by any means, a system of medicine and surgery for nurses, for there are many diseases and surgical conditions which are not even mentioned. The author, however, divides the volume into five parts; Medical, Surgical, Children, Obstetrical and Gynecological.

It would be impossible to cover all of these subjects thoroughly in any one volume, but the author has succeeded in giving a great deal of valuable, and practical information concerning them.

The book is written in simple language, and it is very practical and up-to-date, even though some of the treatment recommended is somewhat different from that practiced in this country. Certainly, the volume is valuable for the group for whom is has been written.

W. S. S.

Facts and Figures About Tuberculosis. By Jessamine S. Whitney. Quarto of 63 pages, illustrated. New York, National Tuberculosis Association, 1931. Paper, 75c; Fabrikoid, $1.00.

Tuberculosis because of its chronicity, its comparative simplicity in diagnosis, and also because it produces a less unfavorable psychic response than many other diseases, peculiarly lends itself to reliable statistical study.

This summary presentation reiterates facts well known to the profession but the statistical data will no doubt make it especially appealing to the public health worker.

And even though we are not fortunate in possessing indisputable statistics for other diseases, it is fairly reasonable to suppose that many of them should keep pace in their more hopeful outlook with this blight on civilization.

Emanuel Krimsky.

Deep X-Ray Therapy in Malignant Disease: A report of an investigation carried out from 1924-1929 under the direction of the St. Bartholomew's Hospital Cancer Research Committee. By Walter M. Levitt, M.B., D.M.R.E. Octavo of 128 pages, illustrated London, John Murray (c. 1930). Cloth, 10/6.

A statistical report of work under the auspices of the St. Bartholomew's Hospital Cancer Research Committee. An interesting review covering 327 cases of malignancy over a period of five years; 1924-1929.

The types treated were:—

50	Carcinoma of	Breast
60	"	" Uterus, 48 of which were of cervix
170	"	" upper air passages
26	"	Rectal
21	"	Miscellaneous

A chapter is given to technic—method of approach and quality and intensity of ray. The report is interesting and well worth reading for comparison with results at other clinics.

The conclusions drawn are:—

1. Malignant growths are at times remedial to radiation, at others palliative.
2. Best results are obtained in the following order of frequency:—upper air passages; uterus and breast; rectal and œsophagus groups poor.
3. When not curative, often marked reduction in size, with alleviation of symptoms.
4. No risk involved—negligible discomfort.
5. In certain cases radium in combination with X-ray is probably superior to either alone.

Milton G. Wasch.

The Diagnosis and Treatment of Brain Tumors. By Ernest Sachs, A.B., M.D. Quarto of 396 pages, illustrated. St. Louis, The C. V. Mosby Company, 1931. Cloth, $10.00.

Brain tumors have long puzzled the profession. Their diagnosis generally implied a fatal prognosis. During the last decade, much light has been thrown on the subject. American physicians, particularly the neuropathologists and neurosurgeons, have contributed the major portion of knowledge that led to a better understanding of the subject. The literature is full of articles on the various phases of the problem. A systematic presentation of the subject, in an easily accessible form, was a crying need. Dr. Sachs has supplied this want. His book is a masterly one, logically written, clearly presented, in a style that is excellent. The bibliography is well chosen and is a means for consulting the original works on the various phases of the brain tumors problem. The book is published in a manner that reflects most favorably on its publishers. One cannot possibly praise the book too much, for it is a work of art. No physician should fail to read it, and no one interested in neurology or surgery should be without it.

Irving J. Sands.

The Science and Practice of Surgery. By W. H. C. Romanis, M.A., M.B., and Philip H. Mitchiner, M.D., M.S. Third edition. Two octavo volumes totaling 1868 pages, illustrated. New York, William Wood & Company, 1930. Cloth, $12.00.

These two volumes are the third edition of this work which have been thoroughly revised. They have been arranged so as to be of great value to the medical student and to the general surgeon.

There are seven hundred and sixteen illustrations, some of which are new, specially selected to present classical reproduction of the various surgical conditions commonly met with.

The first volume begins with general surgical procedures and contains twenty-three other chapters relating to general surgery.

The second volume of twenty-two chapters is devoted to regional surgery.

The authors have been painstaking in making these volumes complete, as one would readily learn from reference to the index.

Ralph F. Harloe.

Clinical Diagnosis by Laboratory Methods. A Working Manual of Clinical Pathology. By James Campbell Todd, Ph.B., M.D., & Arthur Hawley Sanford, A.M., M.D. Seventh edition. Octavo of 765 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1931. Cloth, $6.00.

The seventh edition of Clinical diagnosis by Laboratory Methods preserves all the excellent qualities of the previous editions. Generally acknowledged as an indispensable book in the laboratory library, its value has long been universally acknowledged. A number of minor revisions have been made. New methods which have proven their usefulness are included in this new edition; such as Corper and Uyei's method for the culture of the tubercle bacillus, the Ascheim-Zondek test for pregnancy and many more. The usual recommendation that the clinical pathologist can ill do without this book is emphatically repeated.

Max Lederer.

OUR NEIGHBORS

PUBLIC RELATIONS IN MICHIGAN

The July issue of the Journal of the Michigan State Society contains twenty-two pages of a stenographic report of the proceedings of a special meeting of the Council of the State Society held on May 19, in order to give the public health organizations of Michigan an opportunity to explain their activities and policies. The Chairman, Dr. B. R. Corbus of Grand Rapids, stated that the object of the meeting was to consider state-wide activities for the improvement of the health and social conditions of the people. Since the physicians of Michigan are vitally interested in these matters and must make a decision regarding their relation to them, the Council had been called together in order to hear representatives of the public health organizations explain the purpose and scope of their work. Dr. Corbus said in his introductory remarks:

"The end of the first hundred years of the Michigan State Medical Society came some little time before the war. During this period its activities were quite self centered. They were directed towards better fellowship, ironing out local differences, of which there were many, scientific improvement such as might be obtained by the reading of papers, and the discussion of cases in get-together meetings. All in all the activities were quite largely for the benefit of the individuals composing the society.

"With the ending of the first hundred years of the society, we, for the first time as an organization, engaged in an activity which indicated that we felt that we had a true obligation to the community. This first activity was promoted by Dr. Victor Vaughan, who induced the Society to combine with other agencies to make a survey of the cases of tuberculosis in the state—the first social work, so far as I know, that had been undertaken. Since this time, and most particularly in the last eight or ten years, the Society has become more and more conscious that it has a distinct obligation to the public to do its part in what may be termed 'social work.' Particularly did we feel that we had a duty to the public to instruct them along both public health and personal health subjects.

"Conditions are changing rapidly, and a situation which is interesting to students of social welfare throughout the country, is the availability of money set aside by philanthropic individuals for the improvement of the health of the public through definite health and educational activities. The activities of these splendid philanthropies are directed, in most instances, through Foundations, of which there are several in Michigan."

Dr. Corbus referred to the extensive opportunities offered to the medical profession by the Foundations, and also to the necessity of coming to a working agreement with them. He introduced representatives of five public health organizations, as follows:

1. The State Department of Health.
2. The Couzen's Foundations.
3. The Kellogg Foundation.
4. The Michigan Tuberculosis Association.
5. The State Sanatorium Commission.

State Department of Health: The activities of the Michigan State Department of Health were described by the Commissioner, Dr. C. C. Slemons. He said that the Department consisted of 10 bureaus and 180 employees, and had a budget of $500,000, of which one-half was spent on the bureau of laboratories and biologics. The Commissioner outlined the routine work of the bureaus, and then described the policy of the bureau of rural hygiene which has charge of the establishment of county health departments. The Michigan law is broad and permits counties to establish health departments either singly or in cooperation with adjoining ones. It also gives state aid to county departments of health up to one quarter of their annual appropriations, but with a maximum of $3,000 to any one county.

Doctor Slemons described a training school for county health officers conducted in Lansing with a director supplied by the Rockefeller Foundation; but the doctor adds that the school may be discontinued because of the few county departments that have been organized owing to the meagerness and uncertainty of state help.

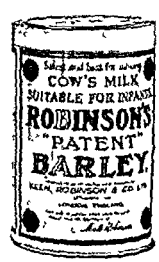
A commendable decision announced by the Commissioner was that no county department of health would be established unless the county medical society of that county asked for it.

As to the minimum expense of a county department of health, Doctor Slemons said:

"We have not approved a unit that showed a budget of less than $12,000. We have figured out that the minimum budget that the sparsely settled counties can get along with is at least $12,000, which gives

(*Continued on page* 1058—*Adv. xiv*)

The *standard* Infant-Diet Modifier



THE addition of Robinson's "Patent" Barley to the diet of the normal, healthy infant breaks down the large clots that result from the curdling of cow's milk and makes the mixture curdle in a manner similar to human milk. Thus the feeding is more easily assimilated.

Its slightly starchy content gradually acclimatizes the baby to the starchy foods which will later form the major part of his diet.

IT IS VALUABLE as a diluent instead of water, because of its soothing, demulcent effect on the stomach and intestines of the baby.

And it solves many of the difficulties of infant feeding. In cases of partial intolerance to milk fat, it is a most successful carbohydrate substitute. The starch in Robinson's "Patent" Barley is absorbed more slowly than soluble sugar...since it has to be converted through the stages of dextrin and maltose to dextrose before it is absorbed. Thus, absorption proceeds gradually and there is no danger of fermentation in the intestines.

In adult dietaries, also...during pregnancy, in cases of intestinal and kidney diseases, and in post-operative feeding — Robinson's "Patent" Barley is used constantly with success.

ROBINSON'S "PATENT" BARLEY is scientifically milled and sealed in tins which protect the flour and preserve its freshness. Readily available in drug stores throughout the country.

Robinson's *"Patent"* Barley

them a county health officer, a couple of nurses, and nurses' expense, and in some instances a sanitary officer. Of that $12,000, the State has paid $3,000. The first year, the Rockefeller people give them $2,500, the second year $1,500, and the third year $750. The fourth year they drop out of the picture. Up to the present time we have had $5,000 a year from the United States Public Health Service that we have been able to distribute among the counties of the State."

There was considerable discussion over the practice of sending patients, especially children with diseased tonsils, to hospitals in Ann Arbor and other centers, instead of to local physicians.

Couzen's Foundation: The second public health organization described to the Council was the Couzen's Foundation, whose program was set forth by Dr. W. B. Carey, who said:

"Some two years ago, Senator Couzens came to the City of Detroit, and called together six men and said that he wanted to set aside some money that could be expended for the children of Michigan. In his own words, he said, 'This ten million dollars is to be expended for the health, welfare, happiness and development of the children of Michigan, and elsewhere in the world, if you reach the point where you think you ought to go outside of Michigan.'

"The objective of our health program is to correlate the local resources which are available, for the betterment of public health, especially for mothers and children. So, in the Division of Child Health, I divided the program up into administration, nursing care (we have 32 counties with nurses in them today); a dental program of some 22 dentists, and 4 oral hygienists, as well as a summer dental program, operating in counties where there are not adequate dental services now available; and a health education program."

Doctor Carey described the work in the Northern Peninsula in which he said:

"You find areas utterly lacking in medical service, unless you say that a doctor who resides forty miles away is available. You find counties without any dental service whatsoever, and, of course, no public health nursing service."

Doctor Carey also described the formation of four consolidated county health departments in sixteen counties, and the aid given by the Foundation, especially in supplying health officers, nurses, and dentists. A local public health committee is established in each department and the help of the local doctors is sought.

The Foundation spent $1,166,000 last year,

(*Continued on page* 1059 *adv. xvi*)

(*Continued from page 1058—adv. xiv*)

including grants to the University of Michigan and Yale for research, and grants for the study of dependent children.

Dr. J. D. Bruce, Ann Arbor, gave the following additional information regarding the rural work in the upper peninsula:

"The Children's Fund of Michigan has erected a building at Marquette, equipped with laboratories, examination rooms, accommodations for twelve children, administration rooms, etc., and an amphitheatre for teaching purposes which will accommodate about seventy-five. The Foundation has given us a sum of money to employ a full-time pediatrician, and we have been very fortunate in securing an extremely well-trained man, who, I am sure, will be very satisfactory to the profession from a teaching standpoint and extremely helpful in the diagnosis and care of pediatric conditions. The plan is to hold, at regular intervals, clinics at Marquette and in the various centers of northern Michigan. There the children that come in will be investigated, and diagnosed, and, when of teaching interest, will be used for demonstration purposes."

Several councillors cited instances of patients who could pay medical fees, being treated free by the staff of the Foundation; and also cases of nurses assuming the prerogatives of the doctor.

The Kellogg Foundation: Doctor Corbus, in introducing Dr. Stuart Pritchard, Medical Director of the W. K. Kellogg Foundation, said:

"I must admit, though, even though I have had several discussions with Dr. Pritchard regarding the Kellogg Foundation, that I am very much in the dark as to what their ultimate purposes will be. Their work thus far has been largely, almost entirely, confined to school work, and building up adequate schools with definite health programs, in the rural communities."

"Their work will always be only in cooperation with the medical profession. In counties where they are working now, he is cooperating with them."

Doctor Pritchard said:

"The purposes of the W. K. Kellogg Foundation are to directly or indirectly become actively engaged in child welfare; to consider ways and means of helping in matters of child health, child education, child recreation, child character building; and to influence school children so that health education may, in turn, penetrate the school, the home, and the community.

SIMPLICITY

S. M. A. is simple to prepare
. . . and requires no modification

Breast milk is simple for the physician to prescribe, yet no physician ever refuses to prescribe it on account of its simplicity, its simplicity, on the contrary is one of the many advantages of breast milk. S.M.A., an adaptation to breast milk is likewise simple to prescribe and prepare and requires no modification for normal full term infants.

CLEVELAND, OHIO

SPECIAL SUMMER OFFER

It has been our custom for many years to make a SPECIAL SUMMER OFFER during July and August.

Prices are based on bulk packing —5000 tablets, 1 gallon liquids and 5 pounds ointment.

A substantial saving can be effected by taking advantage of this OFFER.

"The Foundation supplies the health supervision of the consolidated school for an indefinite period of years with the hope that in the years to come the community will see fit to continue most, if not all, of these activities, so that the work of the Foundation may be transferred to some new field to 'further carry on.'

"The Foundation has no thought of coming in as a competitor in the field of curative medicine. Its chief concern is in the prevention of illness and the maintenance of a high health standard.

"During the entire health supervision program the school boards, the children, parents, and the community are constantly reminded of the importance of the family physician. He is made a part of all programs and is paid for the work he does. The Foundation makes it a rule that no territory is entered without the consent, approval, and promised cooperation of the local medical society, and all matters of procedure are discussed with its executives."

The Michigan Tuberculosis Association: The work of the Michigan Tuberculosis Association was described by Dr. Werle, Secretary, who said:

"The leading social working agency is the medical profession. It antedates by centuries the specialist who calls himself a social worker. Anything we do in tuberculosis work today has behind it the inspiration and the vision of medical men. Many years ago it was made very clear to me in my training that the tuberculosis problem can never be solved by the social worker or the social working profession. It can be solved only by the medical men."

"When the tuberculosis movement was organized, it was organized by medical men, and it has always been under the complete control of medical men. There have been times when laymen have held high executive offices, but there have always been in the Michigan Tuberculosis Association a preponderance of medical opinion and medical men in the handling of its affairs. These medical men, who do work in this field, pointed out to us that the tuberculosis campaign divides itself easily and naturally into two heads. One is in immediate combat with the disease itself wherever it is apparent; and that, of course, is the medical side of the campaign. Then there is the other side, which deals with the disease where it has not yet manifested itself; or before it should manifest itself; in other words, education.

"In an educational campaign against tuberculosis, the tuberculosis association has two purposes in view. One is the education of

(*Continued from page* 1060—*adv. xvi*)

individual children in personal hygiene, with the ultimate goal of an understanding of community hygiene, arousing a demand for an understanding and appreciation of scientific medicine.

"The second point is the education of adults for an immedite effect in community consciousness in health. The immediate effect of that campaign with adults is the provision of money for public health purposes out of public funds."

State Sanatorium Commission: The subject "The Michigan State Sanatoria" was discussed by Dr. E. J. O'Brien of Detroit, who emphasized some of the scientific phases of tuberculosis.

The last speaker was Dr. J. Milton Robb, President of the State Medical Society, who summed up the discussion as follows:

"I do not know any of the problems that you have discussed. As far as I am personally concerned, I only have this one feeling, that the public hygiene gospel should be presented mostly by the men in medicine, providing it is going to stay as a permanent factor in the state. I see no way that a continuous service is going to be maintained. And I think that the feeling of those organizations who are coming in to do the work is that they are laying the foundation for the future, so that the man in medicine is going to be sufficiently trained, so that after they have withdrawn then he will continue; the medical men will continue, with what basic education they have obtained or gotten from this effort, to care for these people in the state. I cannot see, as far as I know, any objection to any of the efforts that I know of. I have this one feeling always, that whatever effort there is developed in the way of teaching, the post-graduate effort, rather than any effort to do otherwise, is found to run a state into a good deal of trouble. If you destroy the individualism of the people of the state, you have destroyed the state. And I know that those who are behind these funds must know better than we do that that is the basic principle from which they cannot deviate."

THE NEW ENGLAND MEDICAL CENTER

Tufts Medical School in Boston is building a group of buildings to be known as the New England Medical Center, for the special purpose of training physicians for practicing in the rural sections of New England. Solving the problem of appetite deficiency

with this delicious chocolate flavor food drink

FOR the patient who will not eat . . . for the child who is undernourished, underweight . . . for the convalescent with sluggish appetite.

Cocomalt is the ideal food drink! Not only does it stimulate the appetite, *but it actually increases the caloric value of a glass of milk more than 70%.*

Cocomalt comes in powder form ready to mix with milk—hot or cold. It is high in nutritive value and tempting even to the fussiest invalid.

Easily assimilated

Cocomalt is composed of barley malt, processed cocoa, whole eggs, sugar, milk proteins and milk minerals, properly balanced and properly converted so as to be readily digested.

Laboratory tests show that Cocomalt contains Vitamins A, B Complex and D. Vitamin D is present in sufficient quantity to be of definite anti-rachitic influence in the child's diet. Cocomalt also helps to digest the starches of other foods.

Available in 5 lb. cans for hospital use, at a special price. Or at grocers and leading drug stores, in ½ lb. and 1 lb. sizes. We would like to send you a trial can for testing. Coupon brings it to you—*free.*

Cocomalt

DELICIOUS HOT OR COLD

ADDS 70% MORE NOURISHMENT TO MILK

R. B. DAVIS CO., Dept. BK-8 Hoboken, N. J.

MANAGEMENT OF OCULAR INJURIES*

By NELSON S WEINBERGER, M D, SAYRE, PA

From the Robert Packer Hospital, Guthrie Clinic.

IT IS with a deep sense of appreciation of the honor that I come here to address your society on the management of eye injuries I trust that what this paper has to offer may be of some interest and will invite free discussion Although this subject may appear rather academic for such a gathering as this is—nevertheless where so important a social and economic function as that of sight is in question—the utmost effort and most meticulous care should be exercised in the management of injury to the eyes Too often an apparently trivial injury develops into a serious state of affairs The preservation of the eye ball often taxes the skill of the ophthalmologist Attempted treatment by inexpert and untrained hands scarcely deserves the stamp of disapproval We have all seen the avoidable bad results and the economic losses therefrom The examination should be made with an open mind and should be routine It should be preceded or accompanied by a careful and painstaking history especially when injury may have been due to a foreign body, flying with sufficient momentum to penetrate the tissues A careful history and examination are often valuable from a legal as well as from a medical standpoint

The steps in examination of the patient for eye injuries are as follows

1 Face and skin for evidence of injury

2 The lid margins, the opening of the glands, the condition of the puncta followed by compression of sac to show presence or absence of chronic inflammation

3 Conjunctival sac—that is, the portion covering the under sides of the eyelids, the globe and in the fornices

4 Cornea—examine for smoothness of surface and clearness of evidence of past or/and present injury The condensing lens—binocular loupe—magnifying glass or/and slit lamp should be used

5 The anterior chamber should be inspected through the cornea by both daylight and artificial illumination The character of the aqueous, the integrity and activity of the iris, the lens, the inner contents and fundus should be examined Finger tension should be taken Fields should be tested

6 If there is no visible injury of the eye the muscle excursions should be tested In the diagnosis of foreign body the symptoms of pseudo-foreign body must be considered—such as Interstitial Keratitis—Acute Iritis—Pigment Deposits—Old Synechia, etc

Sensation of foreign body may be the only symptom of eye strain—Intra ocular studies are made through the ophthalmoscope, the slit lamp, and by roentgenograms

When injury of the cornea is suspected or one wishes to outline its extent—2% Fluorescin should be used Any recent break in the epithelium retains a bright green stain and should a foreign body be present its position is indicated by a dark spot A perforating injury shows no dark spot

Foreign Bodies—If a penetrating foreign body is suspected from examination or history a roentgenogram should be taken If positive —its position and size should be determined by some method of localization We use the Sweet method A careful history will sometimes lead to the discovery of an intra ocular foreign body in cases where examination of the eye revealed nothing Whenever there is any doubt x-ray should always be resorted to An innocent bystander is sometimes the victim X-ray seldom fails to show radiopaque objects In deep foreign bodies where objective examination, x rays and magnetic and sideroscope examination fail Manole uses the chemical reaction of the aqueous to metals as a means of diagnosis The aqueous is aspi-

* Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse N Y June 2 1931

rated and a second extraction is tested with nitric acid for iron or with hydrosulphuric acid for brass and copper. There are numerous methods of localization. The procedures, modifications and contributions of Grundzinski, Gasteiger and Grauer, Speziole-Picaiche, Mcgrigor, MacKenzie Davidson, Stöffel, Patton, Sweet, Snook and Bowen, Holth, Pirie, Comberg, Liebermann, and Gifford only emphasize what Patton remarks—viz., "A variation of a millimeter may determine enucleation." The most generally used geometric method is that of Sweet and the later modification by Snook and Bowen.

Greene emphasizes the importance of extraction of an intra-ocular foreign body as early as possible. Early removal offers better chances of saving the eye—provided infection has not been introduced into the interior of the globe. Fortunately most of the foreign material is hot upon entering and this tends to reduce the risk of infection. There is a great variation in the technique for removal of magnetizable intra-ocular foreign bodies. The avenues of approach vary. Probably the wisest procedure is to manage each case on its individual merits—taking into consideration the point of entrance, structures penetrated, time in situ and location. Any foreign body should be removed with the least traumatism and in the most natural and easiest way. Selection of the so-called anterior or posterior route should be subversive to individual requirements. Most foreign bodies can be removed with the hand magnet such as the Sweet or the Parker. There are times however when the Haab magnet enjoys superior advantages and will remove a foreign body which the hand magnet has failed to extract. Time will not permit me to discuss the details of extraction, owing to the many dissimilar situations and the problems involved.

The removal of non-magnetizable foreign bodies is a different problem. Brass, copper, lead, glass, wood and hair present a far more difficult proposition to handle than the magnetizable foreign bodies.

Cross has devised a method and has successfully extracted lead shot from the vitreous. He uses a specially constructed forceps in conjunction with the double plane fluoroscope.

The eye is very intolerant to all foreign bodies. Polished glass is the least irritating and can be tolerated. Brass and copper are especially offensive. All penetrating metallic foreign bodies will cause low grade inflammation and eventually destroy function in case the eye is not destroyed early by acute infection. The only exception is where a small metallic body is imbedded in the sclera posteriorly. A cilium can be carried in the anterior chamber. So that, in all other instances where an eye harbors an irremovable intra-ocular foreign body safety demands enucleation for social and economic reasons. In every instance where enucleation is not performed for some reason (such as a piece of steel caught in the sclera with good vision or where enucleation is declined) the patient should be made acquainted with the possible dangers and be kept under supervision.

The question of panophthalmitis or plastic uveitis secondary to penetrating foreign body which has been removed comes to us. In this case the eye is destroyed for visual purposes —sometimes the process is very protracted and disheartening. An economic problem is involved. Should it become evident that an eye which has harbored a foreign body is thus affected, its immediate removal serves the indication for the best management of a problem which involves the economic phase regarding employer, employee and employee's family as well as the ultimate cosmetic result. Enucleation of an eye in the presence of infection is condemned by many operators. We would not recommend its general adoption nor should it be done unless one uses no local injections—employs effective antisepsis and does not implant a ball. We have yet to see any untoward results after having enucleated many such eyes and recovery has been just as good as under ordinary conditions. Convalescence is greatly shortened. Protracted illness and incapacity are avoided. Expense to society is lessened. Where enucleation is dangerous simple incision should be made.

Penetrating wounds and contusions—The dangers involved are prolapse of the iris or ciliary body, traumatic cataract, detachment, low grade plastic inflammation, panophthalmitis, secondary optic atrophy, sympathetic inflammation. Prolapses must not be allowed to remain. They should be either replaced or excised depending upon size and location. The iris or ciliary body must not be permanently included in the wound because of distortion of the pupil and the irritation from dragging and low grade infection of the uvea leading in some cases to sympathetic disease. The free edge of the iris must not remain caught near or at the limbus. Should the antero-lateral surface of the iris become glued to the posterior surface of the corneal wound no harm ensues. Traumatic cataract should be treated conservatively. Operation should be reserved for the demands of increasing tension and no more lens matter should be removed than can be easily done to relieve this exigency and conserve vitreous. Prolapse of vitreous and infection must be carefully avoided. Some of the dense secondary traumatic membranous

cataracts should be respected and attacked with trepidation. They are often tough and too much instrumentation may cause undue pull on the ciliary body—a thing to be zealously avoided for a period of a year to two since such irritation might produce low grade plastic inflammation and sympathetic trouble. Traumatic cataract with intact capsule should be needled at the opportune time under thirty, or extracted after thirty.

Dislocation of the lens into the anterior chamber always causes glaucoma and the lens must be removed. In rupture of the eyeball which usually occurs at the angle of the anterior chamber the lens may be forced out under the conjunctiva. A superficial mattress suture should be inserted in the cornea and sclera and the conjunctiva sutured separately. Injuries of this nature are always serious.

Berens and Losey remind us of the remarkable amount of vitreous which may be lost with retention of useful vision. Enucleation in this type of injury (rupture) should not be considered until after a most earnest attempt at saving vision has proved useless and a blind, soft and dangerous eyeball is inevitable. Needless to say a useless and dangerous eyeball should be removed. In all penetrating wounds of the eyeball, tetanus antitoxin should be injected—especially if the surrounding soft parts are also injured. The protein will also serve to produce non-specific resistance to infection. Sub-conjunctival hemorrhage or hemorrhage into the anterior chamber or both may occur. Paracentesis of the anterior chamber is seldom necessary to relieve tension. Intraocular hemorrhage usually offers a fair prognosis if not too extensive and so situated as to cause detachment of the retina.

Extensive breaks in the cornea are best covered by conjunctival flaps. Some of the lesser effects of injury are keratitis, rupture of Descemet's membrane, rupture of the iris sphincter, traumatic dilatation of the pupil, iridodialysis and weakness of accommodation. Partial dislocation of the lens sometimes occurs. Rupture of the retina and choroid demands rest.

Detachment of the retina need not by any means follow when healthy vitreous is lost, either anteriorly or through a wound in the sclera. Practically all writers agree that Gonin's method of treating retinal detachment constitutes a great step in advance. His method of thermo puncture is most successful in recent cases and should never be delayed for other measures which are generally useless. Arruga obtained 50% cures by Gonin's method. In 300 cases Gonin had 12 cases of intra-ocular hemorrhage complicating, six or seven days after operation. Cases over three months duration are unfavorable. While realizing the untoward results and complications reported in some cases yet retinal detachment presents a desperate situation as to sight and requires prompt and efficient measures. Gonin's method was uniformly approved at the Congresses at Amsterdam and at Heidelberg, the percentage of cures by this method being much greater than by any other.

One cannot discuss the management of eye injuries without making some observation on sympathetic inflammation. We now know that this disease is not as frequent as was formerly supposed. Theobald's statistics show that the greatest frequency of sympathetic ophthalmia cases occurs during the first decade. The statistics show that sympathetic ophthalmia is acutally much less frequent than the enucleations done for it or for fear of it. However these enucleations may be justified since we have no means of knowing whether sympathetic ophthalmia or a less harmful infiltrating inflammation will ensue. The best "Cure" for the disease is its prevention. Enucleation prevents it excepting as shown by a review of both domestic and foreign literature made in 1921 by the author. He gathered the reported details of nine cases occurring after enucleation and added one of his own. These were cases reported by such men as Nettleship, Nagel, Müller, Stephenson, Colsmann, Pagenstecher, Genth, Schmidt and McHardy. Questionable ones were excluded. Villard and others have added several since then. In view of this we can say that enucleation practically always prevents sympathetic disease but does not cure it. The exciting eye may ultimately be the better eye. Enucleate for prevention when a potentially exciting eye is useless or will become so. The vision of the injured or exciting eye must be taken into consideration. We are not so quick to enucleate as formerly—yet we must not be too conservative. It is far easier to enucleate than to save some of these eyeballs. We can show real skill by saving useful vision in a badly injured eye. The strictest antisepsis must be exercised.

Foreign bodies of the cornea—Removal of a foreign body from the cornea is not without danger. Infection and unnecessary traumatism should be guarded against. The [illegible] pointed spud is ideal and it should be augmented by the use of a loupe or magnifying glasses under good illumination. The brown ring of iron oxide stain must be removed but it should be done with great care not to produce more loss of corneal substance than is absolutely necessary. The reason for this is the danger of [illegible] ulceration of sharp [illegible]

cornea may cause them to penetrate into the anterior chamber. The importance of the care of foreign bodies of the cornea is regarded too lightly. This is attested by the disasters of preventable corneal ulcers we all see only too often. Corneal injuries from coal, stone, wood, cereal grains, fodder leaves, awns of grains, etc., are dangerous from their inception. Although injuries from metallic foreign bodies seldom develop into serious ulceration—those from the substances just enumerated are very prone to infection and are potential serpiginous ulcers unless immediately treated by antiseptics. The importance of an unclean lacrymal sac as an agent or factor for infection need scarcely be emphasized. An unbandaged eye is cleaner than a bandaged one. Glass splinters usually adhere flatly to the conjunctiva. Tiny objects such as beetle wings, soot, plant particles, etc. usually lodge either in the lower fornix or in the ring-shaped groove over the palpebral margin of the upper lid in the conjunctiva tarsi. Caterpillar hairs have hooked ends and migrate to the cornea or iris. They may cause conjunctivitis or nodule formation resembling tubercle. These have to be removed with a corneal microscope. The depth of a glass splinter can be determined only by the use of the corneal microscope. Traumatic conjunctivitis and erosions of the cornea from burns resulting in ulcer and adhesions may terminate in symblepharon. This should be prevented by the use of oils or ointments and manipulation.

Just a few words on the subject of protein therapy as a means of prevention and treatment of infections. It is good practice to administer tetanus antitoxin in eye injuries especially when the soft parts surrounding the eyeball are involved. Specific therapy is obtained from the antitoxin and at the same time non-specific treatment from the protein. The value of this prophylaxsis was well shown in the late war and it was probably a great factor in the remarkable scarcity of sympathetic disease as compared with the great number and the serious nature of eye injuries. Foreign proteins seem distinctly effective against the staphylococcus and the pneumococcus. There are numerous forms of protein used to increase resistance. Rather than name them all it is better to briefly discuss only a few. Milk has enjoyed wide popularity but it is variable in its potential and toxic action. Its preparation is so delicate in order to be at all effective, that it is probably more often inert and of no therapeutic value whatever. Aolan gives a noticeable reaction and is thought by many to be superior for this reason. Horse serum has many friends because it is a more definite form of foreign protein. As pointed out by Key after thorough experimentation—there seem to be superior advantages in the employment of diphtheria antitoxin. He feels there is some added virtue in the non-specific diphtheric elements (colloids ?) in the serum. Our experience substantiates the claim for diphtheria antitoxin. We use 5,000 units as the adult dose. Contraindications to protein treatment such as asthma, hayfever and also in case of the use of diphtheria antitoxin—previous diphtheria should be kept in mind. Naturally no one relies upon protein alone to prevent or combat infection. The importance of caring for endogenous foci of infection and of blood and urine studies must not be overlooked in combating post-traumatic ocular inflammations and infections. Time does not permit me to go into the details of local therapy nor has space allowed the consideration of injuries other than those to the eyeball itself.

THE ROLE OF THE TONSILS AND THE NASAL ACCESSORY SINUSES IN NEPHRITIS*

By ARTHUR PALMER, M.D., NEW YORK, N. Y.

MENTION of focal infection at once focuses thought on the teeth, tonsils, sinuses and gastro-intestinal tract. Foci elsewhere are less common; indeed the estimate that 75% of all primary foci are to be found above the larynx appears justified if not even conservative.

Acute tonsillitis may precipitate an attack of acute glomerular nephritis. Following exposure and exhaustion, an adult male suffered an attack of acute follicular tonsillitis. In spite of a fever of 103° he drove his car 50 miles to his home. Within 48 hours he showed evidence of acute nephritis with edema of the eyelids and lower extremities. The urine contained albumin, pus cells and granular casts. Clearing up of these signs followed the subsiding of the tonsillitis. Tonsillectomy was performed several months later and no similar attack has occurred during a period of ten years.

Glogau (1) reports the following case: After being operated on for the removal of nasal polyps and the partial resection of a turbinate, a patient carelessly exposed himself to inclement weather and developed an abscess in the left ear. Culture of the pus showed the presence of streptococcus capsulatis. Eight days later a severe follicular tonsillitis developed and the same organism was present in the throat. Five days from this time marked the onset of headache and extreme lassitude, general anasarca and pain in the right thorax. Examination showed the presence of marked edema of the face and legs, with pitting on pressure and the presence of a serous fluid in the right pleural cavity, up to the level of the 6th intercostal space. The urinary examination showed albumin; specific gravity 1022; blood; granular and hyaline casts, with diminished out-put. The tonsillitis disappeared in 10 days, the acute purulent otitis media in 3 weeks and the nephritis in 6 weeks.

Dean (2) states that the relation between glomerulo-nephritis and tonsillitis is startling. Blood colored urine, seen before the removal of tonsils, is often clear as soon as 48 hours after removal. The tonsils are by far the most common harbor of hemolytic streptococci. Rarely, after the removal of faucial and pharyngeal tonsils, has the lingual tonsil to be removed. Occasionally the organism is in a sinus or a discharging ear. Then a satisfactory result can only be secured by the eradication of the infectious process in the sinus or ear.

After a thorough study of 26 cases of nephritis in children, Boyd (3) classifies the source of infection as follows:

	No. of cases	Per cent
Tonsillitis	11	42.3
Scarlet Fever	4	15.4
Otitis Media	3	11.6
Nasopharyngitis	3	11.6
Mercuric chloride	1	3.9
Umbilical infection	1	3.9
Unknown	3	11.6

The usual history of these cases was that of an acute upper respiratory tract infection or a tonsil infection followed in a day or two by partial suppression of urine and hematuria. Slight edema of the eyelids and lower extremities was common. Increase in blood pressure was not marked except in 2 cases. Hematuria lasted from 2 to 4 weeks and tended to recur on the administration of sodium chloride. The average stay in hospital was 2 months. There was fatal termination in 7 of these cases. The series was grouped as follows:

23 Acute glomerular nephritis.
2 Chronic glomerular nephritis.
1 Nephrosis.

The presence of tonsillitis was frequently revealed only by examination of the tonsils. Blood cultures were made in 5 cases and 3 of these showed hemolytic streptococcus. These cases were carefully checked by repeated laboratory examinations of the urine, blood and kidney function. Eye ground examination was negative.

Billings (4) reporting on a series of cases of nephritis studied at the Presbyterian Hospital in Chicago, stated that in more than thirty cases under observation the original focus of infection appeared to be in the tonsillar tissue. He cited numerous case histories illustrating improvement or cure following tonsillectomy. Most of these cases showed blood, albumin and casts.

Bumpus and Meisser (5) pointed out that the increasing evidence that bacteria are carried by the blood to the kidneys and excreted, as demonstrated by the presence of tubercle bacilli in the urine of patients suffering from pulmonary T. B. but with no renal lesions, and the well-known fact that typhoid patients excrete typhoid bacilli in their urine, indicate that renal infection may arise from the bloodstream.

The fact that the tonsils are not enlarged and that pus is not expressed from them does not exclude them as possible foci and it is

* Read before the Medical Section of the Cornell Clinic, March 6, 1931.

their custom to have tonsillectomies performed in all cases in which a urinary infection may reasonably be believed to be of focal origin. They stated that since the adoption of this procedure a surprisingly large number of apparently negative tonsils have been found to hide deep seated virulent infections. On experimenting with rabbits the authors found that the infected material from diseased tonsils and teeth, when properly cultured and injected into the animals, produced definite lesions in the kidneys as well as other organs and the bacteria injected were removed in pure culture from the kidney lesions. A summary of the results showed that lesions occurred in the kidneys in 63 of 82 rabbits injected. They concluded that pyelonephritis may often be due to focal infections harboring streptococcus which have a selective affinity for the urinary tract. Immediately following the extraction of the suspected foci, acute exacerbations of urinary symptoms occurred accompanied by a marked rise in temperature. Such reactions were regarded as clinical manifestations of the specific nature of the bacteria released from the removed focus and such an increase in the severity of the disease was considered favorable and an indication that the right focus had been eliminated.

Generally speaking the study of patients at Cornell, with infection of the tonsils and associated nephritis, corroborates the findings described above: 523 of 989 consecutive patients, who had had tonsillectomies performed at least 6 months previously, responded to a questionnaire relative to results of operation. Of 19 patients suffering from nephritis 11 or 58% were improved or free from symptoms relative to their kidney condition. Not many of the severe or acute cases of nephritis are seen in the Nose and Throat Clinic because such patients require hospitalization.

Mr. A. H. Age 21. Gave a history of passing bloody urine for one month. Medical examination showed tenderness over left kidney. Catherization of ureters showed blood coming from both sides. X-ray of kidneys negative as to size, shape and position. No calculi found. Consensus of opinion was that patient had acute nephritis which was subsiding. Urine examination showed specific gravity 1:015; pus and albumin. Wasserman negative. Several months later patient complained of sore throat and at this time left tonsil was found to be enlarged and diseased. Blood pressure 150/100. About 5 months later tonsillectomy was performed and one year later patient reported having shown no blood in urine and said he had gained weight. Last examination was made in December 1930, 6 years after original visit to Clinic. No complaints were reported and the urine was negative.

Mr. A. B. Age 35. Admitted to Medical Clinic September 3, 1921, complaining of kidney trouble of one year duration, following an attack of influenza. There developed edema of the face and legs accompanied by fever. Patient was in bed from November 1929 to January 1930 and was then treated at the U. S. Naval Hospital. Urinary examination on admission showed the presence of albumin, hyaline casts, occasional red blood cells, few white blood cells. Wassermann negative. Examination in the Nose and Throat Clinic showed the presence of a chronic tonsillitis, pharyngitis sicca, purulent rhinitis. The tonsils were considered the chief focus of infection and a tonsillectomy was performed on January 12, 1930. On August 12, 1930 the patient stated that he felt well and had very little swelling of the legs and ankles except when on his feet for a considerable period.

D. S. Girl 5 years of age. Suffering from secondary anemia, pyelitis and chronic tonsillitis was referred from the Pediatric Clinic to the Department of Laryngology on June 2, 1924. Examination showed this child to be a mouth breather, appearing anemic and below par generally. During the previous 6 months 5 or 6 attacks of vomiting had occurred without an apparent cause. These attacks lasted one day and were accompanied by slight fever. Burning sensation on urination had occurred at intervals for 8 months. The child suffered from headaches. General glandular enlargement was present. On June 20, 1924 a tonsillectomy was performed under general anesthesia and the patient made an uneventful recovery. On January 12, 1925 the mother reported that the child had been free from sore throats and kidney trouble but still suffered from head colds. She was eating and sleeping well; was active and had gained weight. May 13, 1925 this child had continued to improve except for frequency in urination. A few white blood cells were present in the urine. In August 1928 there was some recurrence of the vomiting attacks with irritation of the external genitalia. Vaginal smear showed the presence of pus and gram positive diplococci.

E. G. Adult. Admitted to the Medical Clinic September 12, 1922. High blood pressure for 4 years. Urine showed a faint trace of albumin; no sugar; blood pressure 176/110. Occipital headache in the morning for past 5 months. Chronic rhinitis 6 months. Hoarseness. No pregnancies. Venereal disease denied. Shortness of breath for past year. Aortic second sound accentuated.

Diagnosis: Essential hypertension; pyorrhea alveolaris. Referred to Nose and Throat Clinic for opinion and treatment. Examination

here showed chronic hypertrophic tonsillitis; hypertrophic pharyngitis; pyorrhea. Tonsillectomy was advised and operation performed under local anesthesia November 3, 1922.

Nov. 27, 1922 blood pressure 172/106
Dec. 7, 1922 160/110
Jan. 25, 1922 194/128

Followup January 12, 1925 patient stated that she had less head colds and hoarseness but that kidney trouble appeared to be about the same. Tonsillectomy apparently had no permanent effect on the kidney trouble.

Followup January 25, 1925 patient reported less head colds and hoarseness. Urine clearer. No dyspnea. No swelling of the ankles, hands or face. On diet for obesity.

We now come to quite another chapter where the sinuses are concerned. These structures are above, behind, beside, all but under our very nose, yet how often they baffle us! I wonder if the internist knows how he flatters our curative powers when he nonchalantly remarks "here is a good case of sinusitis for you. Clean up these sinuses and then send the patient back to me." The patient is cleaned up and cleaned out, perhaps of everything but his sinusitis, until among the laity the slogan seems to be "once a sinus, always a sinus." Certainly the sinuses are not above reproach in respect to many things, nephritis included. Yet a search of the literature reveals the fact that articles on the sinuses in relation to nephritis are conspicuous by their absence. Only occasionally in the course of articles on allied subjects is reference made to this relationship. Too long have sinuses been a dark continent where the physician feared to tread or where he carried out experimental treatment with the feeling that he was walking on uncertain ground. A considerable mass of data regarding them has been accumulated but not well correlated as yet. Much about sinuses still demands explanation. For example: (1) The disproportion between symptoms and signs. Many people suffer intensely from sinus infection while clinically little pathology is found, or on the contrary a quantity of pus may be present in the nose and nasal accessory sinuses and the patient complain of little except discharge. (2) Rapid relief of eye conditions, as neuroretinitis with central scotoma and sudden impairment or loss of vision, may follow the opening of the ethmoid-sphenoid labyrinth when little demonstrable pus or pathology is present. (3) Not infrequently also, curetting of diseased tissue in chronic sinusitis fails to cure the condition, in fact may aggravate it. (4) The role of allergies, diet, glandular imbalance and bacterial invasion as etiological factors in sinusitis. As one observer, Proetz (6) so well expressed the situation "what we need is less action and more thought. The mere mention of red swollen membranes is a red rag to some of us. Swollen ankles get only passing attention. Pus encountered in the nose is a sign that nature is at work successfully expelling noxious agents from our confines and while I do not view it as a signal for jubilation I see no occasion for hysteria in regard to it."

Many of the above remarks may seem to be aside from the question, "The Role of the Sinus in Nephritis" but they may explain to a degree some of the diffculties in the way of establishing a correct relationship.

Theoretically at least the sinus may be a focus in respect to a kidney lesion due to some focal infection, just as is the tonsil and associated lymphoid tissue in the pharynx.

Byfield (7) states "In our long series of cases we found certain disorders brought into more or less close association with sinus infection. Chief among these were chronic cough and nephritis, (and there is some evidence to suggest that the chronicity of the renal process may be due to sinus infection) pyelitis and diphtheria.

Dean (8) cites two cases where the elimination of sinus disease seemed to be responsible for the elimination of pyelitis. Certainly the rhinologist urgently needs the cooperation of the internist if the solution to many of these problems is to be found. The internist, after all, is the commanding officer, the specialist, but one of his aides.

An interesting case from Cornell Clinic follows: An adult male was admitted to the Eye Clinic November 1, 1930, with a history of sudden loss of vision for past 2 weeks.

Diagnosis: Acute neuro-retinitis. Ophthalmoscopic examination revealed swelling and edema of the nerve heads, retinal hemorrhage and exudate, sclerosis of the retinal vessels and increase in blind spots. X-ray of the sinuses, Wassermann examination and general medical examination were ordered. The case was referred to the Nose and Throat Department for further examination of the sinuses as a possible etiological factor. On the same day examination in the Nose and Throat Clinic showed the presence of a deflection of the nasal septum and the presence of sinusitis. X-ray of the sinuses showed a clouding of the antra, sphenoids and frontals, especially the right frontal. Wassermann negative. Coagulation time 5 minutes. In consultation with the Eye Department an immediate drainage of the sinuses was considered advisable. Contrary to the usual custom this operation was performed before any general medical examination had been made. A submucous resection

of the septum was done as a preliminary step to the drainage of the sinuses. In the midst of the operation on the right ethmoid cells a profuse hemorrhage occurred necessitating packing the nose and discontinuing further operative procedure. The unusual amount of bleeding suggested to the operator that high blood pressure might be a factor. On April 3rd, the following day, the packing was removed and hemorrhage from the right side followed. Systolic blood pressure was 190. Medical consultation was arranged and the internist reported that the patient was unable to distinguish faces but could see a person. The patient was muscular, robust but appeared anemic and weak because of loss of blood. The heart was slightly enlarged to the left, sounds were loud and ringing, pulse rate normal, under tension.

Diagnosis: Chronic nephritis; hypertension. Patient was transferred to the New York Hospital for further care. The report at the New York Hospital showed red blood cells 1, 730,000; hemoglobin 32%; white blood cells 10,500; polys 87%. Repeated urine examinations were made which showed albumin, occasional white blood cells. Wassermann was negative. Urea nitrogen 110 milligrams. Uric acid 20 milligrams. Urine reduced, 312 c.c. passed in 4 hours after digestion of 1500 c.c. Red test too light to read. Examination of the eye grounds showed evidences of old and fresh hemorrhage, outlines indistinct. Blood pressure ranging from 170 to 180 systolic; 102 to 130 diastolic. Patient ran a febrile course and was in bed two weeks, around the ward for two weeks and then allowed to go home with instructions to return to the out-patient department.

In the words of Pawlow, "It is only when the full etiology of disease is known that the medicine of our day can become the medicine of the future. That is to say, hygiene in its widest sense."

Conclusions

(1) Experimental and clinical evidence establishes the fact that the faucial tonsils are a definite focus in certain cases of infectious nephritis.

(2) The sinuses are a probable focus in certain cases.

(3) Wholehearted cooperation of the internist and the laryngologist is essential to the best results in handling cases of nephritis where a focus of infection is considered the *etiological factor.*

HERPES ZOSTER AND VARICELLA*

By EUGENE F. TRAUB, M.D., AND JESSE A. TOLMACH, M.D., NEW YORK, N. Y.

In recent years much has been written concerning the relation of Herpes Zoster to Varicella. Since Bokay,[1] in 1888, first called attention to the association of the two diseases, numerous similar reports have been made. Varicella and Herpes Zoster are both vesicular eruptions in which the individual lesions are frequently clinically and histologically similar. This fact was recognized by Darier.[2] According to Delmas,[3] the clinical test between generalized Zoster and Varicella is the radicular topography of the former, and only in the absence of this radicular topography can Varicella be diagnosed. This is a rather extreme view and we do not believe that such difficulty in diagnosis exists except in unusual cases. To claim a relationship between the two diseases, two factors must be proved. In the first place, the diseases considered separately and also in association with each other must show similar variations in incidence. In the second place, a common etiologic agent must be demonstrated. We shall attempt to show that neither of these points is satisfactorily proved. Two cases in which both diseases existed in the same patient were encountered by us and are being reported here.

Case Reports

Case I.—P. L. M., male, aged 56, appeared at the New York Skin and Cancer Hospital on June 25, 1930, complaining of a generalized rash. The

* Read before the Clinical Society of the Stuyvesant Square Hospital, April 24, 1931.

patient stated that, to the best of his knowledge, there had been no exposure to chicken-pox either at home or at his place of business. He had never had chicken-pox, and the only previous illness he had suffered from was the "flu."

Present Illness: Seven days before his admission to the hospital, he noted the appearance of a "blister-like" eruption on the right side of his face, extending up to his scalp. This eruption gradually became more marked, and one day previous to this examination, a general eruption made its appearance on the body.

Examination: The eruption of the right side of the face and forehead was made up of grouped vesicular lesions on an erythematous base. There was a marked necrosis of the lesions together with a swelling of the entire right side of the face. Scattered over the rest of the body were numerous small vesicular lesions, some of which were umbilicated and some hemorrhagic. The temperature of the patient was 99.4 F.

FIGURE 1
Profile showing Herpes Zoster of the right side of the forehead of the patient referred to in Case I.

Case II.—J. H., male, aged 56, was seen by Dr. Traub in his private practice on October 10, 1928.

Past History: The patient stated that he had never had chicken-pox and denied any exposure to it. His past history was otherwise irrelevant.

Present History: Sometime during the first week of October, the lymph glands behind the left ear and at the back of the neck became swollen. Massage and "opening" medicine failed to relieve the swelling which, although not very painful, gradually became more marked. The patient claimed he felt a tingling sensation in his left ear and in his left arm. On October 7th, the patient noticed a blister on the back of the left ear and on the following day, a bright red spot on the left shoulder.

Examination: When seen by Dr. Traub on October 10th, a diagnosis of Herpes Zoster was made. The patient returned to his home and during that night he complained of "feverishness" and profuse perspiration. On the following morning, the face and body were covered with a vesicular eruption typical of Varicella.

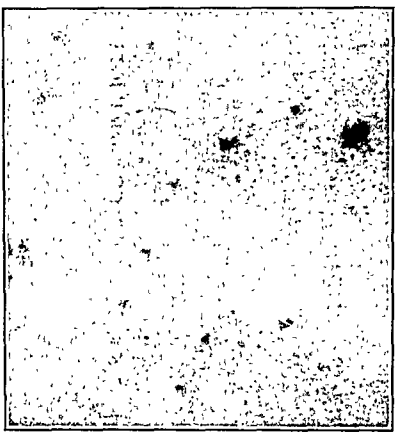

FIGURE 2
Same patient as Figure 1 *showing varicella of the trunk.*

In both of these cases, a typical attack of Herpes Zoster was followed, in the same patient, and within four to six days, by chicken-pox.

REVIEW OF THE LITERATURE

Instances of the coincidental appearance of Herpes Zoster and Varicella were reported by Le Feuvre[4] in 1917 and by McEwen[5] in 1920. The former encountered seven cases in his own practice in four years. The latter collected thirteen cases in which the two diseases were associated. Examples of concurrent Zoster and Varicella were reported in more or less detail by Aviragnet, Huber and Dayras,[6] Gautier and Peyrot,[7] Roxburgh and Martin,[8] and Seymour.[9]

According to Roxburgh and Martin, cases of concurrent Varicella and Herpes Zoster may be regarded as due to dissemination of a virus which, in the first instance, attacks certain posterior nerve roots only, the virus being that which causes Varicella. Bokay,[10] too, advanced the theory that under certain unknown conditions, the infective agent of Varicella can produce a local Zosteriform eruption instead of a generalized exanthem; the Zoster is thus an expression of Varicella, and contagion is readily passed to others. This may explain cases such as that reported by Dainville and Reyn[11] in which two weeks follow-

ing the occurrence of Herpes Zoster in the mother of a nursing child, the latter contracted chicken-pox. The child was confined, at that time, to a creche and she was immediately isolated. Two days later, 15 other cases appeared and no transmittors other than the mother with the Zoster could be found.

J. Shelmire and B. Shelmire[12] described a case in which, during the course of Herpes Zoster of the right 5th nerve distribution, a patient developed a generalized, extensive vesicular exanthem, closely resembling Varicella. Singularities of the Zoster eruption in this case were the involvement of the right half of the tongue, buccal mucous membrane of the right cheek and motor paralysis of the right half of the face, infranuclear in type. The generalized eruption following the Zoster was extensive, involving the glaborous skin of almost the entire body, the oral mucous membrane not already the seat or Zoster lesions, and the scalp. Fourteen days after the appearance of the Zoster in the father, a daughter who had not been previously exposed to chicken-pox, developed a clinically typical Varicella eruption with lesions of the scalp and mouth. The disease could not be transmitted to rabbits by inoculation of vesicular fluid into their scarified corneas.

The negative results observed after the inoculation of the Zoster material into the scarified corneas of rabbits in the above case, are in accordance with similar negative findings of Cole and Kuttner.[13] Many more cases of the association of the two diseases are on record, and a report of all of these would only be superfluous.

Interesting experiments conducted by Kundratitz[14] seem to point to a closely related or identical virus in Zoster and Varicella. He produced a varicellous eruption in 17 out of 28 children whom he gave intra-cutaneous inoculations of fluid from typical Zoster lesions. None of these children had ever previously had chicken-pox or Zoster. Lipschütz[15] found in several of these provoked varicella-like eruptions, nuclear inclusions described by him as characteristic of virus disease. Glaubersohn and Willfand[16] reported findings similar to those of Kundratitz. Kundratitz and Lipschütz[17] also claimed that injections of convalescent Herpes Zoster serum will protect exposed children against Varicella.

On the other hand, Lauda and Stöhr[18] inoculated 54 children with material from 17 cases of Zoster, and in none of them did they observe a local reaction at the site of inoculation. These workers were unable to demonstrate that convalescent Zoster serum protects against Varicella and concluded from their work that the majority of cases of Zoster are not caused by virus of chicken-pox.

Complement fixation tests done by A. Netter,[19] Netter and Urbain,[20] de Lange[21] and others, seem to indicate that the virus in both these conditions is frequently identical. These observations were not, however, confirmed by Lauda and Silberstein.[22] Results of experiments conducted by Eldridge and Rivers[23] on monkeys, indicated that the etiological agents concerned with these two diseases were not identical.

Very interesting and pertinent figures were gathered by Rivers and Eldridge who found that in New York City during the years 1914 to 1926, 95,994 cases of chicken-pox were reported. At the Bellevue Clinic, 425 cases of Herpes Zoster were observed in the same period of 13 years, and 159 cases were seen at Vanderbilt Clinic during the years 1922-1926. Examination of the tables and figures dealing with the incidence of Varicella and Zoster reveals the fact that a remarkably constant seasonal variation occurs in the number of chicken-pox cases reported, while such variation in the prevalence of Zoster is not very obvious. Here we might note the report of Cantor[24] who stated that on Christmas Island, Straits Settlement, chicken-pox is unknown, while the usual amount of Herpes Zoster is observed.

Conclusions

Two cases are reported in which Herpes Zoster is associated in the same patient with Varicella. The mass of reports and the experimental work to date do not prove beyond question any relationship between the diseases. Some of the cases may simply be pure coincidences, just as any other two or more diseases may occur in one patient at the same time. Another point is that it is quite possible that the same agent that causes Varicella may in some cases produce local manifestations similar to Zoster. Highman[25] stated that true Herpes Zoster has no connection with any other disease. The Zoster may be due to some micro-organism that causes Varicella. In other words, they may be different clinical expressions of the same agency; but Zoster-like eruptions are not true Zoster. Further investigations may prove a relationship between the two diseases, but at the present time, there is not sufficient evidence to prove that the association of true Herpes Zoster and Varicella is other than a chance coincidence.

THE SO-CALLED ACUTE ABDOMEN FROM THE STANDPOINT OF THE GENERAL PRACTITIONER AND THE INTERNIST*

By CLAYTON W. GREENE, M.D., BUFFALO, N. Y.

A FRIEND of mine, as a McGill medical student in 1883, watched Osler autopsy a case of appendicitis and Osler remarked—"If this man had been operated upon he would have got well." That was years before McBurney's classic paper. Similar observations had been made by others. Extraordinary progress in our knowledge of the surgical lesions in the abdomen, and in our capacity to treat them, has been made since that time. Yet, today, the literature abounds in references to the appalling present death-rate in appendicitis. Something is wrong with our present collective handling of the problem. Other acute abdominal lesions as well help to swell the mortality. Other and wiser heads may clarify the situation for us, but I shall attempt to discuss only one phase—the part played by the family physician. Outstanding and clearly cut signs and symptoms make the diagnosis of acute abdominal lesions comparatively easy in many cases. Others, however, tax the keenest minds, even when supported by all the diagnostic aids available to modern medicine. Fortunately, these "mystery" cases are not frequent.

It is not desirable at this time to attempt to discuss all, or even many, of the lesions producing abdominal emergencies. The textbooks of today cover the ground thoroughly. But it may be well to examine a bit into the general problem and to discuss general principles which should underlie our conduct. Such knowledge as we possess perhaps has not been used at all times to the best advantage of patient and physician.

It is probable that more than 90 per cent of the cases of the so-called acute abdomen are seen first by the medical men. Consequently, it were better that a symposium on the acute abdomen be given in a medical section rather than a surgical one. Most of you will agree that the majority, but by no means all, of the mistakes made in the acute abdomen are made by the man first on the case—the medical man. It has long been a belief of mine that the best possible training for a surgeon is to be a medical man first for at least a year or two. Likewise, it would be a great asset to a family physician to have some experience in surgery under well-trained teachers, in order to have a first-hand experience in surgical diagnosis.

Upon the physician who is the first to see the acute abdominal case rests the greatest responsibility. He must recognize the urgency of the situation and determine the proper course to pursue. If he is lax or dilatory the patient may experience unnecessary weeks of suffering, irreparable damage to his physique, and may even lose his life. When the doctor is called, it is evident that an emergency is at hand. He is confronted at once with two problems. First—is the lesion causing this emergency located within the abdomen? Second—if it is in the abdomen, is surgical interference warranted? His decision should be prompt, but it should be based only upon careful investigation. Correct treatment can rest only upon correct diag-

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 3, 1931.

nosis. Snap diagnosis may be impressive but it is unsafe.

A short history of the present attack is essential. Pain is usually an outstanding feature and its character, location and radiation should all be noted. Its association with bodily functions is important. Inquiry should be made as to vomiting, and particularly its relationship to pain. In many cases vomiting does not occur but is replaced by nausea or anorexia. The anorexia is produced by the same cause as the vomiting and is just as important in making a diagnosis. Note should be taken also of other disease present—pneumonia, typhoid fever, cardiac disease.

The physician should proceed promptly with the examination of the patient. The first glance may suffice. The anxious, perspiring face may point to the shock of perforation or pancreatitis; or a death-like pallor with air hunger may be the evidence of a ruptured ectopic gestation. Examination of the abdomen should come first. Distension is rare at the onset but may appear soon afterward. If present, it may indicate intestinal obstruction, peritonitis, or hemorrhagic or other free fluid in the abdominal cavity. A scaphoid, rigid abdomen occurs almost alone in perforation of a peptic ulcer. Rigidity of the muscular wall is present in most emergencies. It is marked in perforation, but may be slight in hemorrhage and absent in the early stages of appendicitis. The most important physical sign is tenderness on pressure, which tenderness is increased as the pressure is increased. It is the one blue chip, the outstanding sign of all.

Temperature and pulse rate are often of little value. It should be remembered that many acute conditions are afebrile until late or throughout their course, while occasionally—particularly in children—a temperature of 103° F. or more may be found early in appendicitis. It is unwise and sometimes fatal to wait for the appearance of fever in a case of suspected abdominal lesion. Likewise, marked changes in the pulse may be of assistance in diagnosis, but a so-called normal pulse should not alter one's judgment of a serious condition. The full, low tension pulse may be considered characteristic of peritonitis.

Lesions outside the abdomen which may simulate the acute abdomen are chiefly in two groups—pulmonary and cardiac. Pain of a diaphragmatic pleurisy or of a pneumonia near the diaphragm may be referred to the abdomen, and muscular rigidity may be present. There is no tenderness, however, unless it be close to the diaphragm, and usually there are distinctive changes in the rate and character of the respirations and physical signs in the chest. In pericarditis much the same picture may be present, except that respiratory changes are usually slight. In coronary occlusion pain referred to the abdomen may be very severe, rigidity and distension may be present, but there is no tenderness. The accompanying restlessness forms a contrast to the enforced quiet of peritonitis. Other signs of pulmonary or of cardiac disease may be elicited by careful examination. Pain in the abdomen with nausea and vomiting may be evidence of a gastric crisis in tabes dorsalis. Careful examination should establish its identity without much trouble.

Another group of cases may be classed as acute abdominal, namely—lesions of the urinary tract. Pain and rigidity may be present and even slight tenderness along a ureter, if it be involved. Tenderness usually is found over one or other kidney, pain is referred to the groin, there is frequently a tender spot at the symphysis on the corresponding side, and nearly always there are significant urinary findings.

In the stage of reaction from shock, the appearance may be quite deceptive. Color may be good, respiration normal, pain lessened. It is here that many mistakes are made. The semblance of comfort presented by his patient misleads the physician into believing that he cannot be very ill.

With his prompt recognition of the fact that an acute abdominal lesion is present, excluding the renal ones, there is but one course for the physician to pursue. He must at once have his patient treated surgically by a competent surgeon. In all but a few cases this means early operation. If he is in doubt as to the exact nature of the intra-abdominal lesion, the physician had best postpone differential diagnosis until he can attempt it in company with the surgeon. Delay in obtaining surgical care is absolutely inexcusable.

Many cases are not so outspoken as has been indicated. Here again many lives are lost while the physician awaits more definite signs. Our commonest abdominal lesion, appendicitis, often is ushered in with mild symptoms and very few signs. The physician who suspects that his patient may have appendicitis should see him again in not more than six hours. To do otherwise is gross neglect. Meanwhile that patient should be kept as quiet as possible, with absolutely no cathartic or enema and no opiate. Opium relieves pain and gives the patient comfort, but it masks symptoms. The false sense of security it affords both patient and physician may be but the precursor of tragic progress of the lesion and subsequent death. A leucocyte count should be done and the urine examined as soon as possible. There can be little excuse for

neglecting these two, and there is none for the physician who plans his next visit on the morrow As soon as the diagnosis of appendicitis is made, operation should be done I am skeptical of those who claim they can tell the progress of the changes in appendicitis by signs and tests I beg to differ also with those who deny the value of leucocyte counts Often they are the one aid to differentiate indefinite cases A small, inexpensive but efficient microscope can be carried in the bag or in the coat pocket, and a leucocyte count with at least a chamber differential count can be done in ten minutes A rectal examination should always be done Often it gives no added information or even none at all, but on occasion it may be of service in saving a life In all, but particularly in children, an inspection of the nose and throat should not be omitted

It is cause for sadness that the rising mortality in the acute abdomen is due not alone to mistakes in diagnosis, but to neglect upon the part of the medical attendants Let me cite two flagrant cases A young physician saw a woman patient and told her he thought she had a tubal pregnancy which was beginning to leak He said, "Now you come to my office tomorrow at two and I will be there to see you ' The patient did so, but the physician was not in She went on to a nearby city and consulted a surgeon who found the lesion as suspected by the younger man and removed it Another recent graduate told a mother that her child had intussusception but that he would watch the child carefully, which he did for four days Surgery when offered at last was unavailing The laity sometimes put us to shame To a medical friend of mine an excited mother's voice called over the telephone—'O Dr Blank, hurry right over—the baby has intussusception!" She was correct, for she had lost another child with a similar attack one year previous

A man somewhat older than these two, who boasts that he always operates upon his own cases of appendicitis, told a mother "Your child has an appendix but we'll watch it" After he had watched it for a week the case was transferred to another town where a surgeon at immediate operation drained a large appendicular abscess Mistakes occur of course It is probable that there may be for generations a small irreducible minimum of mortality in appendicitis, due to the rare cases, gangrenous from the onset, which exhibit absolutely no pain until perforation has occurred But what excuse has the physician who makes a definite diagnosis of a serious surgical lesion and then neglects to offer the proper remedy?

I have spoken of the competent surgeon A kid was shot in the right hip one evening He complained of pain anteriorly in the abdomen In the morning a surgeon was consulted Finding the bullet in the front of the abdomen outside the peritoneum the surgeon felt he should investigate it to see if any damage had been done within the peritoneum Directly beneath the bullet was found a gangrenous appendix—a coincidence Any but an able surgeon would have been content to withdraw, having found the bullet, and the boy's life would have been lost Yet promptness in surgical interference is usually of prime importance One is reminded of Dr Deaver's statement that in perforation early operation by a mediocre surgeon is better than a too late operation by a master And better a needless operation than a needless death

Another duty of the family physician is a proper attitude of hands off in the surgical postoperative care The ingestion of fluids and food, the use of opiates, the employment of laxatives or enemata, are all best handled by the surgeon for the first few days at least The physician may assist greatly with moral support and co operation and particularly in the handling of complications of a medical nature

To summarize, we may say The part of the family physician is to recognize at once that the acute abdomen is present in the patient and that prompt surgical care is imperative His next duty of prime importance is to eliminate medical conditions which may simulate the acute abdomen He should employ no laxatives He should give no opiate until after the diagnosis has been made When such a part is played by the men first to see the cases, our mortality in the acute abdomen will subside remarkably Its present height has been due to causes which have been aptly epitomized by my friend Dr John J Morton of the University of Rochester—"laxity and laxatives" Laxity on the part of the patients, yes—but laxity on the part of the physicians also Laxity and mistakes "For our blunders, O in shame before the eyes of Heaven we fall" Ignorance and indifference—both phases of the greatest curse of mankind—selfishness The patient's needs should always come first No physician should lay down his head at night until such an emergent case has had proper care or is in other competent hands

PHYSICAL THERAPY IN INFANTILE PARALYSIS*

By RICHARD KOVACS, M.D., NEW YORK

PHYSICAL therapy properly correlated to orthopedic measures has produced valuable results in convalescent and chronic cases of the last epidemic of infantile paralysis. These results should be generally known so that this knowledge will not have to be acquired again by costly experience. In addition, reports have come in recent years from France and Italy about the successful use of diathermy and roentgen therapy in the acute stage of anterior poliomyelitis.

1. *Treatment of the Acute Stage*

The acute stage begins with the onset of the disease and lasts until the tenderness and pain have entirely disappeared from the paralyzed muscles. It is now generally agreed that its pathology is not only an affection of the anterior horns of the spinal cord, but also a polio-myelio-encephalitis with meningeal complications. There is exudation, hemorrhage and edema in the anterior horns, along the nutrient vessels entering from the meninges and along the spinal nerve roots and the pia. The circulatory interference and mechanical pressure upon the sensitive ganglion cells and the possible specific effect of the virus are responsible for the suspension of the conduction of motor impulses to the periphery and result in flaccid paralysis and atrophy in scattered muscle groups. The acute stage usually lasts several weeks. The routine treatment of the active stage consists in keeping the patient recumbent and the paralyzed muscles at rest. Plaster cases are being used and joints are immobilized in a position in which the affected muscles are relaxed. This procedure hastens the disappearance of pain and is essential for the prevention of deformities, and also prevents the overstretching of the paralyzed muscles by the healthy antagonists. However, it does not keep the muscles in the best possible condition and does not influence the pathological changes in the cord.

It would seem rational that the earlier the mechanical pressure on the cord is relieved, the quicker and the more complete might be the recovery. The fact that many cases show full recovery with rest and expectant treatment alone should not lead to therapeutic nihilism. Bordier[1] states that the average results are better following early treatment by spinal roentgen therapy. The beneficial action is due to the prevention of the sclerosis and the atrophy which tend to destroy the nerve cells near the seat of the myelitis; the improvement is brought about mainly by an indirect action on the peripheral edema and on the pericellular infiltration. In conjunction with radiotherapy, Bordier advocates diathermy along the affected extremities, in order to overcome the circulatory disturbance and to facilitate muscle response by its heating effects.

French and Italian observers have practiced Bordier's method and found that the extension and intensity of paralysis were appreciably and constantly diminished by early radiation. As to the use of diathermy, two French observers, Delherm and Mathieu,[2] state that it is especially indicated in older children with vasomotor and trophic disturbances, but that in younger children it should be avoided on account of their inability to discern the sensation of burning. On account of this danger, they prefer the galvanic current for its mild and safe heating effect.

Competent observers in this country, like Granger,[3] have employed direct spinal diathermy to extensively paralyzed cases with apparently good result. In the average case luminous heat was applied over the spine and the paralyzed musculature for an hour or more at a time. Granger emphasizes the pain-relieving properties of this treatment. The little sufferers usually sleep right through the treatment. The author prefers thermal radiation from an infra-red generator because of the absence of possible irritation from the visible rays. Such treatment can be applied with the patient in bed and does in no way interfere with immobilization. It is recommended that during the acute phase every child should receive heat radiation for the relief of pain and the improvement of circulation and nutrition of the affected parts.

2. *Treatment of Convalescent and Chronic Stage*

The greatest field of usefulness of physical therapy exists in the convalescent and chronic stage of infantile paralysis. The convalescent stage may last from one to three years and is characterized by the tendency of the paralyzed muscles to recover their tone and power. On account of this tendency it is somewhat difficult to evaluate the effects of treatment unless there is a method by which one can determine beforehand which muscles are apt to recover spontaneously, which ones need physical therapy and which ones are going to remain permanently paralyzed.

Electrodiagnosis through testing for the reaction of degeneration by the faradic-galvanic current or, still better, by the modern condenser method enables the skilled physician (1) to express quantitatively the extent to which the muscles are affected, (2) to make a prognosis of the improvement to be expected, (3) to select the most appropriate form of therapy. Muscles without RD will recover spontaneously or the re-

* From a paper, "Physical Therapy in Pediatrics," read before the Pediatric Section of the New York Academy of Medicine, November 13, 1930.

covery will be sped up by appropriate therapy; those with RD may show varying degrees of affection and should receive treatment as early as possible. A careful electrical test of the affected areas is, therefore essential for the survey of a patient with poliomyelitis in the convalescent stage and for planning the treatment. It can be performed in a simple and satisfactory manner even in small children by testing a whole limb at one time, for instance, placing one electrode under the buttock and another under the sole of the foot. In older children careful individual motor point testing can be done, which is practically painless if milder condenser discharges are used.

A less accurate method of examination and grading the existing muscular power is that of testing muscle action against gravity and outside resistance. A person having had intensive training in muscle action is needed to carry out this testing. McMillan's[4] classification recognizes four degrees of normal action, from full normal to ¼ normal (N to ¼ N) in which the muscle is still capable of limited action if gravity is eliminated; Q—where the muscle shows a quiver but is capable of no movement and T.P.—where the muscle shows no sign of movement, being totally paralyzed. This corresponds with full RD found on electrical testing.

It is fortunate that the greater majority of muscles are weakened rather than paralyzed and precise, effective and intelligent treatment enlarges greatly the field of possible complete recovery. The object of treatment is to prevent the trophic changes which take place when muscles are deprived from normal nerve stimulation and to facilitate the return of normal function. Splinting for the protection of the weakened muscles against the pull of the powerful antagonists must be continued.

Heat in the form of radiation from an infra-red or luminous heat generator or from a hot (105 to 110°) whirlpool bath serves as the main standby to improve circulation and nutrition and to prepare the parts for subsequent exercise or electrical treatment. In cases where internal heating seems desirable, diathermy shall be carefully applied along the length of an extremity or through the spine.

"The well being and efficacy of a muscle is largely dependent on the performance by it of a certain number of active contractions. When a muscle is inactive for any length of time, it atrophies. It is an accepted physiological principle that the exercise of the normal functions of a muscle is the best means of increasing its size and strength. The same rule applies to the partially paralyzed muscle" (Lovett[5]). Tilney[6] says: "Muscle prevented from performing its natural function of contraction tends to revert to non-contractile connective tissue type. It remains for us to supply the deficient function of contraction by whatever means we possess. Electricity is one of these means."

Massage and muscle training are the two universally recommended means of restoring muscles affected by infantile paralysis. Do they preserve the function of contraction? Of massage, Lovett[5] says: "It can only be expected of proper massage that it will improve locally muscular tone and nutrition and antagonize muscular atrophy and nothing more. It will not restore muscular power." Stookey[7] says: "Modern experimental evidence proves that massage is only of slight benefit in preventing atrophy of paralyzed muscles." In paralysis, according to Mennell[8] only the slightest form of massage is indicated because, owing to the atrophy of the paralyzed muscle, pressure may be transmitted to the blood vessels, causing paralytic dilatation; thus, heavy massage will defeat the end sought. In our own cases of paralysis, we use massage only as an adjunct for the further improvement of local circulation; very light massage for from five to ten minutes at a time to one extremity is all that is indicated.

Active exercise as accomplished by muscle training is undoubtedly the most natural form of reeducation of weak muscles. Its disadvantage is, first, that only older children can be trained. Lovett recommends their beginning at the age of 3, and Ogilvy[9] at 6. Tilney[6] says: "Muscle reeducation to be most efficient requires an elaborate system of accessories and a well trained staff of instructors. With one conspicuous exception, no such efficiency has yet been attained." If the muscles are without any power, the passive performance of the motion, as recommended, is undoubtedly inferior to active contraction by electricity. Muscle training can and should be applied systematically alongside the electrical treatment, and the latter should be abandoned in its favor as soon as there is a return of active muscular power.

The rationale of electrical stimulation is based upon the following considerations: If the muscle is not fully paralyzed, but only weak, the causing of contractions not only prevents the atrophy of the paralyzed muscle bundles but also exercises and strengthens the non-paralyzed part and thus enables it to do compensating work. In fully paralyzed muscles electrical stimulation can cause movement similar to the normal ones and thus tends to preserve the functional properties of the muscle until normal nerve impulse returns to carry on the work. Every case of infantile paralysis, no matter of how long standing, which has not received proper physical therapy is a good subject for electro-therapy (Kovacs[10]). The sudden improvement in some old cases soon after efficient treatment has been instituted can be explained by the fact that there are a number of unimpaired ganglion cells present in the anterior

horns and they in turn are connected with intact nerve tracts and muscle fibers. By suitable electrical and reeducative treatment these non-paralyzed muscle fibers redevelop and are transformed from an inactive minority into an active majority.

Electrical stimulation to be effective must be carefully planned and skilfully applied for a sufficiently long period. According to the electrodiagnostic findings, the slow or interrupted sinusoidal is used in cases with RD and the surging faradic in cases with absence of full RD. Treatment does not consist of simply slapping on two wet pad electrodes somewhere along an extremity and by turning on some form of current as powerful as possible. Badly directed and badly applied treatments of the past were mainly responsible for the indifferent if not decidedly antagonistic attitude of some medical men towards electrotherapy in infantile paralysis.

Technic of Electrical Stimulation

The most effective method of electrical treatment is that of *unipolar* muscular stimulation. A large dispersive electrode is placed under the cervical or lumbar spine or at any place central to the lesion, and a small active electrode over the individual muscles. In case of RD the normal motor point is displaced distally (towards the tendon) and to save time at subsequent treatments it is advisable to mark with indelible pencil the most effective point of stimulation for each muscle.

In fully paralyzed muscles one must be well aware of the danger of over exercising a muscle by electricity. I do not believe that more than a flicker of the tendon is necessary to prove a successful contraction in a paralyzed muscle. This flicker may not even be visible; it is enough when it is palpable to the trained finger at the insertion of the tendon. From three to ten contractions of each muscle are ample at the start with an increase to the maximum number effected gradually. A careful operator will very quickly notice that a larger amount of current is needed in case of a muscle that has been overtired previously.

Preceding and during electrical treatment, the affected extremity should be placed so that the paralyzed muscles are relaxed and not kept on a stretch by their healthy antagonists.

According to the response elicited in turn, each muscle is made to contract from half a dozen to a dozen times, the number of contractions being increased until from thirty to forty a minute is reached and a maximum treatment of from two to three minutes to an individual muscle or fifteen minutes to an entire extremity is given.

Treatment with a *bipolar* technic or "en masse" consists of placing two electrodes of suitable size at the opposite ends of an extremity; for instance, one electrode may be applied to the sole of the foot, the other under the buttocks or under the sole of the other foot. The surging current passing along the entire extremity results in a fairly even contraction of all muscles provided that their response is about equal. It is almost uncanny to see how different muscle groups first on the flexor then on the extensor surface of an extremity contract gently without any electrode touching them. Another method in bipolar technic consists of using the galvanic bath method. One may place the two hands separately or one hand and one foot or each foot separately in a basin of water connected to the source of suitable low tension current.

The bipolar technic is a lazy operator's method because after placing the electrodes in position and turning on a sufficient amount of current, he can stand by and let the current do the rest. It is advisable only if the muscles of the extremity are all nearly evenly affected. It offers the advantage to treat for instance a whole extremity suspended in a cast. Treatment is started at ten minutes duration and this is gradually increased according to the response.

Electrical treatment applied with proper technic never needs to be painful; in nervous children it might be advisable on first sitting, following the preliminary heat treatment, to apply the electrodes without turning on any current. This will facilitate their getting used to the situation.

Underwater Exercises

The use of underwater exercises (submarine pools) in subacute and chronic cases has been introduced in recent years by Lowman[11] and others. They are carried out in a heated indoor swimming pool so constructed that children or adults with paralyzed limbs can be easily placed into it and while there be suspended in a harness fastened to an overhead trolley. The sustained heat in the pool improves the circulation and nutrition of the parts and has a relaxing effect on spastic limbs; the buoyancy of the water takes weight off the body and allows an easy movement of weakened or paralyzed limbs. The patients float about comfortably in the water and a technician puts through exercises suitable to their condition. Muscles too weak to act against gravity will thus have a chance to work freely, provided they are capable of active voluntary contraction. This method offers an excellent combination for the treatment of spastic and paralytic conditions but requires facilities that are only available in a few institutions. It does not offer the possibility of individual stimulation of paralyzed muscles, as electricity does. Its general tonic and stimulative effects are unexcelled.

As combined orthopedic support and physical therapy is systematically carried out, the atrophy of muscle groups in which recovery was to be ex-

pected gradually disappears and muscle response improves. Long persistent treatment is the keynote of success, skilfully utilizing all therapeutic measures and avoiding overtiring of muscles at any one time. It takes a long time for the regeneration of muscles to become complete after the original attack and therefore much can be accomplished even at a later stage in aiding the regenerative process in the muscles. It is an interesting experience to note the sudden improvement of some of the old cases soon after proper treatment has been instituted. "It is almost as though there were some latent recovery lurking in the muscle, needing only the electrical stimulus to reveal its presence" (Turrell[12]).

Electrical testing repeated from time to time demonstrates the progress made and enables its charting; it also demonstrates the total lack of response in some of the muscles; in case of doubt, careful observation and treatment of these may be carried on for a while; if the lack of response persists, the replacement of these muscles becomes a problem for the orthopedic surgeon.

Conclusions

1. Physical therapy is indispensable for the restoring of power of paralyzed muscles following poliomyelitis. Heat, muscle training combined with electrical currents of low tension and low frequency are the most effective measures.

2. Cooperation of the pediatrician, the orthopedic surgeon and the physical therapist are imperative for the best interest of the patient.

3. The earlier proper physical measures are employed, the more satisfactory will be the results. Definite technic and persistency in the measures instituted will bring acceptable results even in late and neglected cases.

TINNITUS*

By EDWIN S. INGERSOLL, M.D., ROCHESTER, N. Y.

TINNITUS is a subject which has been a matter of interest and concern to Otologists since the earliest writings in the field of Otology, and rightfully so since there is no other symptom of ear disease that causes more distress to the patient or more problems to the practitioner. While deafness in its different forms is the chief complaint with which we have to deal, it is, from the patient's point of view, by no means as aggravating and harrowing an affliction to live with as is a loud and ever present "ringing in the ears."

Deafness, unless it be practically complete, is often improved by treatment and even though treatment fails, the use of artificial aids so frequently brings function up to a practcial level that these patients are able to enjoy a more or less normal existence.

The patient suffering from tinnitus, however, has no escape, and unless he be of the most phlegmatic temperament, the psychological effect of this continuous noise often leads to the most serious consequences. Insanity and suicide are not infrequently the direct result.

In view of the widely recognized seriousness and prevalence of this condition it is somewhat surprising that modern otology has not made more progress toward its alleviation. The literature of the last fifteen years has not added a great deal to our knowledge. The writings of Woakes as early as 1884 give a remarkably complete exposition of the subject and while new theories have been advanced since his time due to later developments in the knowledge of anatomy and physiology, it is safe to say that any improvement in treatment has been almost negligible. Many new things have been tried with varying results, but on the whole the sum total of advancement has been disappointing.

This is a field wide open for research, the

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 3, 1931.

successful results of which would rank, in terms of human happiness, at least equally with anything that may be accomplished in the studies of Otosclerosis or Progressive Deafness.

True tinnitus aurium is subjective and there should be a distinct separation made in the classification of sounds reported by the patient. The so-called entotic noises, clicking and snapping sounds, such as are produced often voluntarily by the contraction of the muscles of deglutition on the eustachian tube or by the contraction of the stapidius or tensor tympani are not sounds with which we are particularly concerned, certainly it is only in the most nervous of individuals that such phenomena assumes any importance and an explanation as to their cause, even in the case of a highly neurotic patient, is sufficient to allay any concern he may have.

It is a frequent occurrence to have this type of sound make its appearance during the course of treatment for chronic catarrhal deafness when the tight eustachian tube begins to lose its congestion following the use of the bougie and inflation. This sound can usually be heard through an auscultation tube. Another kind of noise that is often objective is that produced by some defect in the circulatory system outside of the inner ear such as an anurism of the carotid, and which can often be stopped temporarily by pressure.

Sounds of this kind, while disturbing to the patient in proportion to their intensity and to the nervous stability of the individual are not of peculiar importance to the Otologist, nor do they often reach the point of becoming a major menace in the life of the possessor as is all too often the case with true tinnitus aurium.

By true tinnitus is meant the sounds interpreted as singing, buzzing, ringing and roaring, simulating bells, running water, peanut stand whistles, etc. The sounds may be low or high pitched, the latter probably most often associated with otosclerosis, and they may be intermittent or continuous, in many cases being noticeable only in the most quiet places or following fatigue. At times the sound takes the form of a tune as in the case of a woman music teacher who complained that a noise which had previously been a rather innocuous buzzing had developed into a well pronounced reproduction of "Nearer My God to Thee."

An analysis of 163 cases complaining of tinnitus has not been very productive in information of a positive nature, but of some importance in its negative aspects. In this series the ages ranged from 8 to 78 years with only four under 23 years, the average at the time of examination being 43, and the average age of the onset of tinnitus was 26. Thirty-eight of these patients presented the phenomenon of Paracusis, and in several the onset of tinnitus antedated any appreciable degree of deafness.

There appears to be no relationship between the percentage loss of hearing and the severity of tinnitus and in several cases there was no demonstrable hearing loss and a disturbing noise was the only complaint. Several authors, notably Politzer, say that tinnitus is often noticed before deafness and that tinnitus accompanies 66% of deaf cases. This figure seems to me to be high. It is sometimes astonishing, however, to find how deaf a person may be, especially in one ear, before he himself is conscious of the fact, but there are certainly some cases in which tinnitus has become a troublesome factor before any hearing loss is demonstrable by audiometer or other tests.

The functional activity of the auditory nerve as shown by bone conduction, also seems to play no part in the production of tinnitus. In the cases studied in this series some had a bone conduction almost negligible while others ran to over 30 seconds on the basis of a normal of 12 seconds. So it would seem that the study of deafness by the commonly used clinical methods will not lead far in the solving of what is a more rare condition, but one which, when it reaches a certain point, becomes a far more disturbing factor in the life of the patient. Deafness, while it often does produce morose changes in the character of an individual and may sour his attitude toward life, does not often lead to melancholia or a true psychosis as is not infrequent in severe cases of tinnitus.

It has generally been assumed that anything that varies the normal endolymph pressure, whether upward or downward, may produce tinnitus. If this is accepted as the necessary physical condition required to produce the symptom, it opens a wide field of investigation regarding the various mechanisms which bring about this pressure change and because of the many known contributing causes, it makes the investigation of any individual case a tedious, and unfortunately in the majority of cases, a futile procedure.

The fact that children very rarely have tinnitus is well recognized. Sturm of Edinborough ascribes this to the fact that in children the vestibular aqueduct is relatively very wide allowing an uninterrupted flow of endolymph into the saccus endolymphaticus, and a wide cochlear aqueduct permitting free passage into the sub-archenoid space, thus providing a situation which tends to maintain an even pressure on the endolymph.

Congested eustachian tubes, impacted cerumen, furunculosis, diffuse external otitis, acute and subacute otitis media, or adhesions in the

middle ear following suppurative processes or chronic catarrhal changes, the fixation of the stapes in otosclerosis, are among the commonly accepted causes.

In those cases where there are adhesions from the cushion of the eustachian across the fossa of Rosenmueller, relief of symptoms sometimes follows the breaking up of these adhesions, but it has been temporary in my experience. Further experimentation in this connection may lead to more permanent results.

There have been many remedial measures tried both on physiologic and empiric grounds. Mallison of London has recommended Dilute Hydrochloric Acid drams 1 t.i.d. F. P. Sturm of Edinborough reports successful results from the use of atropine sulphate instilled in the ear through a perforation of the drum or introduced through the tube by means of a catheter using grains 5 in alcohol to oz. 1 aniline oil. He accounts for the results on the theory that the paralyzing effect on the secretory fibers of afferent nerves from peripheral sources such as the tympanum controls the reflex lymph secretion of endolymph.

H. Mortimer Wherry of London stresses the bilateral tinnitus of high or low blood pressure and advises treatment by the Internist rather than by the Otologist advising the use of nitrates in the high blood pressure cases.

Bruhl and Albrect in Berlin, and also Sobotsky, reported on the use of Radium. Bruhl's report was rather optimistic. Sobotsky reported one cured, ten improved, twelve not improved, and two worse.

The "reflex" conditions, many of them proven causes of tinnitus, offer an interesting field for conjecture as to just what pathological processes are involved. McBride of Edinborough cites cases cured by cocanization of the sphenopalatine ganglion. I have tried this several times without result.

There are, however, two sources of reflex irritation to which I would like to call your attention because I have satisfied myself that they are the determining causative factor of a few cases of distressing tinnitus. They may be widely known, but I have been unable to find any reference to the first one while the second was mentioned but once in the literature I was able to find.

The first is a relaxed condition of the temporo mandibular joint of one or both sides such as rather frequently occurs when there has been a disturbance of the normal closure of the teeth. This joint has become accustomed to a certain bite for a long period of years and has been splinted in a certain closed position. With the wearing down or loss of teeth, notably the grinders, this closure has become altered with a consequent strain on the temporo mandibular joint, resulting in a greater or less degree of subluxation with stretching of the joint capsule. I have referred these cases to a dentist who has for several years been interested in this type of thing; his interest having been aroused by the case of his own father who had a subluxation which caused some inconvenience in eating. On correction of the condition he found that he had stopped tinnitus and also greatly reduced his hearing loss. Whether the hearing was actually benefited or whether the relief of an overriding tinnitus resulted in a relative improvement, I do not know.

By the use of appropriate plates and checking the joint position by x-ray examination, the strain is relieved and the cases where this is the only cause of tinnitus, are quickly improved. The condition is easy to diagnose by palpation of the joint in motion.

The second, and probably much more widely recognized cause of tinnitus which can be remedied is found in the impaction of molar teeth. This is a condition which should always be looked for and corrected if present. I have had several very satisfactory results following the removal of impacted molars.

As to the mechanism of the cause of tinnitus in the two foregoing conditions, I have no explanation, but there have been enough cases resulting in improvement following their correction that there is in my mind, no question of the relationship. Unfortunately there is but a small percentage of cases falling into this classification.

It is difficult to foresee what may be the future methods of treatment of tinnitus cases where the cause would appear to be some organic pathological change such as fixation of the stapes or the presence of dense adhesions where such drastic measures as the cutting of the acoustic nerve had given disappointing results. But there is undoubtedly a certain percentage of cases where the cause, while it cannot properly be called functional, is of a reflex character and can be relieved. If this type of cause be carefully searched for and corrected as is often possible, we will at least have made some progress.

CLINICAL ASPECTS OF PHOSPHATURIA*

By LOUIS H. BARETZ, M.D., BROOKLYN, N. Y.

THIS paper was prompted by three cases of phosphaturia of distinct clinical interest.

The condition known as Phosphaturia cannot in itself be considered a pathological entity, but for purposes of study, such a nomenclature may be generally employed for the not uncommon condition of cloudy urine due to a precipitation of phosphates.

The literature on the clinical aspects of phosphaturia has been particularly meager. Phosphaturia is of interest to the Urologist and the Gastro-enterologist as well as the general practitioner; yet, comparatively little knowledge has been brought to light, altho of recent years, increased interest has been manifest.

Types of Phosphaturia: The "transient phosphaturia," frequently seen, is considered metabolically normal, and this condition will not be discussed at any length.

Neither shall we include at this time the phosphaturia with marked infection, familiar to the Urologist, which occurs with a chronic alkaline cystitis, producing the so-called "contracted bladder" and incrustation of the mucosa with phosphatic deposits.

Of interest here, is what may be termed the "persistent phosphaturia," producing a cloudy, alkaline urine (1) without infection, or (2) with a low grade infection as evidenced by a moderate number of white blood cells.

Laidley[1], in an excellent survey of the subject with special emphasis on the experimental side, terms this type—"permanent phosphaturia." I would prefer the term—"persistent," since many of these cases are cleared up by treatment.

Etiology: The two types of phosphates in which we are mainly interested are (1) the inorganic phosphates of Sodium and Potassium, i.e. the "alkaline" phosphates (so-called, because of the alkaline metals, Sodium and Potassium;) and (2) the inorganic phosphates of Calcium and Magnesium, i.e., the "earthy" phosphates. With the organic compounds we are not concerned.

Laidley shows that the earthy phosphates, occurring in the ratio of 1:4 as compared to the alkaline phosphates, are much less soluble. Therefore, any change in the solution which renders it more alkaline, causes a precipitation of the earthy phosphates. Experimentally, this is done by the addition of NH_3; or in the bladder, by the NH_3 formation of urea-splitting bacteria. Here, the NH_3 forms Ca and Mg Ammonium phosphates which are insoluble.

The great bulk of phosphates, as shown by Leffman[2], are derived from food, or indirectly from the phosphoric acid derivatives of the same. The old theory of phosphaturia, connected with degenerative changes in brain and nervous system, because phosphorus compounds are notable constituents of such tissue, is no longer tenable.

Baehr[3] says: An excessive loss of hydrochloric acid in the gastric juice disturbs the acid-base regulating mechanism of the body; and normally there is a diminution of the acidity of the urine corresponding to the secretion of acid in the stomach after meals. Therefore, he adds, *phosphaturia is caused by an exaggeration of the normal alkaline tide.* This is further increased by the excretion of salts derived from vegetables and most fruits with a predominantly alkaline ash. The normal diet provides a considerable amount of Ca and Mg so that the more easily precipitable form of earthy phosphates is present.

Experimental increase of phosphorus in the diet, as shown by Baehr and Laidley, does not increase phosphaturia, and in the transient form of phosphaturia, there is no increase in phosphatic excretion.

It is unlikely, but not impossible, that earthy phosphates can be secreted thru the renal tubules in the precipitated condition. Yet, on many occasions, earthy phosphates are precipitated in the renal pelvis or in the bladder, or not until the urine has been voided.

What keeps these salts in solution when the reaction is alkaline? Laidley believes in the existence of a "protective colloid property." Remove this and the salts precipitate. Young[4] feels that this phenomenon is bound up with surface tension. A foreign body in the bladder which lowers the surface tension, will be rapidly encrusted with phosphates.

Beer[5], in an interesting preliminary report, believes that phosphaturia is not a metabolic condition, but rather a peripheral and local disturbance. Further studies have not been published by him, nor have his impressions been corroborated elsewhere.

Many observers believe that the cause of a persistent non-infected phosphaturia is due to (1) neurasthenia, or (2) inability of the bowel to excrete earthy phosphates.

Laidley points out the interesting fact, that the cases of neurasthenia with phosphaturia, are often associated with a chronic prostatitis or seminal vesiculitis, and that the urine or

*Read at a meeting of the Brooklyn Urological Society, March 10, 1931.

prostatic smears contain organisms capable of culture and these are of the urea-splitting type, and thus ammoniacal urine and subsequent phosphaturia result.

He further demonstrated, that in a series of transient phosphaturia cases, in no case were the earthy phosphates in greater quantities than normal. The total phosphates were within normal limits, and the alkaline and earthy phosphates bore a normal relation to each other. However, in a series of 33 cases of persistent phosphaturia, the interesting fact was brought out that there was an absolute increase in the earthy phosphates.

Renner[6] also believes that non-infected persistent phosphaturia is due to an increase in urinary calcium which has been brought about by partial or complete inability on the part of the bowel to excrete its share of the body's calcium. Experiments of Domarus and Tobler, he states, also favor this theory.

In persistent phosphaturia Laidley feels some constant factor must be introduced: (1) a constant decrease in the alkaline phosphates; or (2) a constant increase in the earthy phosphates; or (3) inhibition of the protective colloid.

To sum up: The persistent non-infected phosphaturia is either associated with neurasthenia or intestinal derangement. Why neurasthenia causes phosphaturia is obscure. Urologists feel that phosphaturia causes neurasthenia. The weight of evidence shows that persistent phosphaturia is caused by an absolute increase in the earthy phosphates due to an inability on the part of the large bowel to excrete its proper amount of earthy phosphate.

Symptomatology: The patient may present no symptom referable to the urinary tract, and a routine examination may reveal a persistent non-infected or mildly infected phosphaturia.

Such an individual, may however, at some time complain of burning during micturition; or at the end of the act (terminal dysuria); urgency; frequency; perineal discomfort. There may be a story suggestive of a typical renal colic, on one or both sides. Frequently there will be constipation, colitis, a history of taking large doses of bicarbonate by mouth to relieve "indigestion." Such symptomatology may be associated with hematuria, as described by Gray[7].

The urine examination will reveal a cloudy specimen, alkaline to litmus, and a sediment showing many crystals of triple phosphates. There may be actual slugs of phosphatic concretions, and at times, red and white blood cells. One of the cases noted below, complained of a whitish discharge after bowel movement or urination associated with "sharp pain and streaked with blood." In the presence of white cells, a smear will frequently reveal organisms.

Neurosis is a frequent associated condition. Phosphaturia is often present in individuals with hyperchlorhydria; in these cases, the gastric symptomatology may be stressed and the urinary symptoms overlooked.

The frequent association of renal colic and phosphaturia leads one to believe that the colic may be produced by a shower of phosphatic crystals passing down the ureter, similar in nature to the so-called "uric-acid shower." Frequency, urgency, dysuria etc. are similarly produced by vesical irritation. Cystoscopy in these individuals may reveal masses of crystals or phosphatic debris on the mucosa often in the neighborhood of the ureter orifices, while Urographic study is negative.

Treatment: If associated infection is present, such as a seminal vesiculitis or prostatitis, these foci should be eradicated by routine persistent massage.

In the event of a non-infected persistent phosphaturia, dietary treatment is fundamental.

The urine must be kept acid; the alkaline tide must be reduced. Much can be accomplished toward this end by omitting base forming foods by mouth. Food with an alkaline ash such as vegetables or fruits should be omitted or greatly minimized. To a lesser extent, those foods which stimulate gastric secretion, should be decreased. Administration of acids by mouth as acid sodium phosphate or other urinary acidifier, is indicated.

Attention to constipation, colitis, or other bowel disorders is of paramount importance, so that a more normal calcium excretion via the intestinal tract may be produced, thus tending to return to normal quantity the excretion of phosphates in the urine.

Removal of psychic factors has been stressed by some authors.

Cystoscopic treatment, is as a rule unessential, if the proper dietary regime is followed. In the event of persistent renal colic or vesical symptomatology, however, cystoscopy is indicated.

Case Reports

(1.) M. F. age 32, married, complained of a whitish discharge after urination or defecation, associated with sharp pain and occasionally streaked with blood. There was occasional left lumbar pain. Diurnal frequency q.2.h. and nocturia 2-3 times each night.

Examination revealed an apparently healthy male, of distinctly neurotic makeup. There was tenderness in the left lumbar region. The urine was hazy, alkaline, and examination of

the sediment revealed several wbc's, many rbc's, numerous crystals of triple phosphates, and large cocci in chains on direct smear. The second specimen of urine voided was more cloudy than the first, and at the end of micturition, there was a whitish discharge streaked with blood. Examination of this discharge showed slugs of phosphatic crystals and debris. The seminal vesicles were distinctly enlarged and smear after massage revealed several pus cells. Cystoscopy showed numerous crystals in clumps grouped about each ureter orifice and at the base. The orifices themselves were normal. A left catheterization yielded clear urine, free of wbc, or crystals. Flat X-Ray and lft. pyeloureterogram were negative.

The patient was put on a diet increasing meats and reducing vegetables and fruits, routine massage of the vesicles was instituted, and soon afterwards, for the first time in many months, his urine became crystal clear, and he was symptom free.

This case illustrates a phosphaturia, with associated renal colic, excess alkaline diet, and seminal vesiculitis.

Case II. L. G. age 49. Patient complained of pains in the prostate and in the shoulders for many years. There was a history of an old Nisserian infection. Additional complaints were perineal discomfort, and occasional severe attacks of right lumbar pain, without radiation and without associated urinary symptoms. There was marked constipation. His diet was mainly vegetarian.

His urine was always turbid, alkaline, loaded with phosphates, and a heavy sediment containing a moderate number of wbc, occasional rbc, and large cocci on direct smear.

X-Rays of the urinary tract, cystoscopy with right ureteral catheterization, and pyelography were always negative.

Massage of an irregular lumpy prostate yielded a smear containing many pus cells.

The right sided attacks were always associated with gaseous distension, and large quantities of gas were visualized in the X-Rays taken at the time.

Following colonic irrigation and almost a fasting diet, symptoms would disappear and the urine become almost clear.

Massages of the prostate associated with a reduction of vegetables from the diet, and attention to bowels, have rendered the patient symptom free, and the urine clear.

This case illustrates a phosphaturia, associated with infected prostate, renal colic, constipation, and excessive vegetable diet.

Case III. J. B. age 34. Patient had been troubled with "gas" for 1 year, for which he had been on a diet with a minimum of meats. He took Bicarbonate frequently for heartburn and resorted to colonic irrigations at intervals.

For past 3 weeks has had right sided colic with associated urgency and frequency of urination. There was radiation of the pain toward the pubis and no dysuria.

Present attack began 12 hrs. before coming to the office and was so severe that a hypo was given.

The urine was cloudy, alkaline with a large sediment of phosphates, and loaded with rbc. Abdomen was distended with gas. There was a positive right Murphy and tenderness in the right costo-vertebral angle.

X-Ray disclosed large quantities of gas and an apparently negative urinary tract.

The patient was put on a diet free from vegetables. Meats and cereals were increased. Bicarbonate was discontinued. Bowels were made to move freely. Two days later, his urine was clear for the first time in 3 weeks, and patient was free of symptoms.

A subsequent cystoscopic study was negative.

One month later, following an overindulgence in a Thanksgiving dinner, there was recurrent constipation, right sided pain, frequency and phosphaturia. Similar treatment cleared up the symptomatology, and there has been no recurrence to date.

Again, this case illustrates the syndrome of (1) phosphaturia, (2) vegetable diet, (3) renal colic, (4) and intestinal disorder.

CONCLUSIONS

1. "Transient" phosphaturia is caused by a number of metabolic factors, most of which cause an increase in the total alkalinity of the body fluids. The kidneys excrete the excess of alkali and the earthy phosphates are precipitated. There is no deviation of the phosphatic content from normal.

2. "Persistent" phosphaturia is frequently associated with (a) low grade infection of the prostate or seminal vesicles; (b) inability of the bowel to excrete its share of the earthy phosphates. There is absolute increase in the urinary phosphate content here.

3. The associated symptomatology is varied: there may be typical renal colic (crystal shower), urgency of urination, frequency, perineal discomfort, dysuria, constipation, gaseous distension, etc.

4. The urine examination shows a cloudy specimen, alkaline to litmus, and on sedimentation—heavy phosphatic deposits, triple phosphate crystals, frequently red and white cells.

5. Treatment:
   (a) Massage of prostate or vesicles if infection is present.
   (b) Eradicate constipation, colitis, or other intestinal disorder.
   (c) Keep the urine acid by reducing the alkaline tide. Omit or reduce base forming foods such as vegetables and fruits. Increase meats and cereals.
   (d) Urinary acidifier by mouth.
   (e) Remove psychic factors.
   (f) Cystoscopic treatment if indicated for renal lavage.

LABORATORY AIDS IN THE DIAGNOSIS OF UNDULANT FEVER*

By RUTH GILBERT, M.D. and MARION B. COLEMAN, B.S., ALBANY, N. Y.

From the Division of Laboratories and Research, New York State Department of Health, Albany, N. Y.

EXPERIENCE with undulant fever demonstrates the great variation of clinical manifestations which different cases may present. The severity of the disease ranges from a transient malaise lasting for a week or two, and no doubt often subclinical, to a prostrating illness which may recur from time to time over a period of years. Acutely toxic cases may simulate typhoid fever, and the work of Amoss, Bull and others[1,2,3,4,5] has shown that, as in the latter infection, the incitant may at times localize in the gall bladder. A more chronic form of the disease may be mistaken for tuberculosis. The cough, night sweats, temperature fluctuations, and subjective symptoms may render the differential diagnosis particularly difficult. In some instances, it has been considered as a somewhat atypical form of malaria in regions where the latter is prevalent. Hardy and his co-workers[6] have suggested that the illnesses designated as "typho-malarial fever" during the Civil War were probable cases of undulant fever. Acute forms of the disease, with cough, bronchial symptoms, and malaise the outstanding features, are frequently diagnosed as influenza or "grippe," and more severe cases with the pulmonary symptoms intensified, as bronchopneumonia. Manifestations of arthritis, sciatica, and pain in the lumbar region or abdomen may complicate the diagnosis.

Infections with organisms of the abortus-melitensis group in cows, goats, and hogs result very frequently in localization in the genitourinary organs. The serious economic loss due to infectious abortion in cattle and hogs is generally appreciated. Physicians nevertheless have been somewhat loath to consider infection with organisms of this group when patients have presented symptoms indicating involvement of the genitourinary organs. A number of instances are mentioned in the literature, however, in which abortion in women has been associated with undulant fever. Kristensen and Holm[7] isolated *B. abortus* from a placenta in one case, from the vaginal discharge following abortion in another, and also from an ovarian cyst. Carpenter and Boak[8] have recently reported the isolation of *B. abortus* from a human foetus. Gaarde[9] and others[10,11] have commented on the frequency of nephritis in patients having undulant fever. Hardy[12] has noted manifestations of orchitis in five per cent of male patients with undulant fever, but in one-third of these cases the symptoms were not severe. Wainwright[13] has also reported orchitis as a frequent complication in this disease. Clinical histories accompanying specimens examined in the Division of Laboratories and Research in Albany for evidence of infection with organisms of the abortus-melitensis group have, in thirty-four instances, indicated the presence of lesions in the genitourinary organs. One case was of particular interest. The patient was acutely ill with clinical manifestations suggestive of typhoid fever. Her serum agglutinated *B. abortus* in a 1:1200 dilution and the microorganism was isolated from the blood. Five urine specimens were examined during and following her illness, but from only one of these was an organism isolated similar to that found in her blood. This specimen was collected about three months after recovery and six months after the onset of illness, and contained menstrual blood, which suggested that the bacteria had probably remained in the endometrium rather than in the kidneys.

In view of the extremely protean nature of the clinical manifestations of undulant fever, laboratory aids in its diagnosis have proved particularly helpful. The most generally used and readily applicable of these is the agglutination test. Preliminary determinations demonstrated that the reactions obtained with *B. abortus* and *B. melitensis* were so nearly identical that one antigen only needed to be employed. *B. abortus* was chosen for routine use since it seemed to give slightly more sensitive results and was considered somewhat less dangerous to handle than *B. melitensis*.

* Read at the annual meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 3, 1931.

In the examination of 106,879 specimens in the central laboratory in Albany and in the branch laboratory in New York City, 705 gave reactions with *B. abortus* antigen in a 1:80 or higher dilution of the serum. The percentage of those submitted for different types of examination which were found to agglutinate is of interest. A reaction was obtained with one in nine of those accompanied by information indicating that a diagnosis of undulant fever was considered; with one in eighteen of those from patients thought to have an enteric disease; and with only one in 248 of those submitted for the complement-fixation test for syphilis. Probably the percentage of patients presenting symptoms of a febrile disease in the latter series was small. Tables 1 to 4 show the degree of reaction obtained with the specimens which agglutinated *B. abortus*. The data available in regard to the agglutination test with sera from human patients correlated with the information derived from a study of the disease in cattle and other animals convinces one that a definite reaction indicates the presence of infection with a strain belonging to the abortus-melitensis group, provided tularemia can be excluded, or that the individual has had undulant fever in the past. Failure to obtain agglutination does not exclude undulant fever, as is illustrated by an interesting case studied by Miss Dacey* at the branch laboratory. An organism of the abortus-melitensis group was isolated from the blood of this patient received three weeks after the onset of symptoms. The serum, however, did not agglutinate *B. abortus* even in low dilutions and agglutinative properties could not be demonstrated in a second specimen received two weeks later. The history of the case indicated that the

patient had had clinical manifestations of undulant fever two years before, at which time she had been severely ill.

Isolation of the microorganism from the blood of a patient of course definitely confirms the diagnosis of undulant fever. Hardy and his associates[6] have emphasized the difficulty encountered in securing cultures from the blood in case the infection is due to a strain derived from cattle. Strains from goats and hogs apparently can be isolated in a much higher percentage of instances. A study made in the Division of Laboratories and Research of cultures secured from patients with undulant fever in New York State indicates that although some of them do not fulfill certain of the criteria for classification as bovine strains, a consideration of the data available indicates that all belong to this group. Epidemiological evidence suggests also that cattle or dairy products have been the source of the infection in most of the cases. No history of contact with goats has been reported and very rarely could hogs be considered. In the preparation of blood cultures, the inoculated medium should be incubated promptly Duplicate preparations should be made, one to be kept under the usual aerobic conditions and the other to be incubated in an atmosphere containing from 5 to 10 per cent of carbon dioxide. The blood should be secured when the patient has a febrile reaction and a series of specimens should be submitted. The desirability of having several specimens examined is emphasized by the experience of a physician who had undulant fever and wished to have the diagnosis definitely confirmed. The onset of illness was in August. Blood cultures were made from specimens collected on September 27, October 3, October 9, and December 8, but the inciting organism was isolated only from the specimen taken in December. Incidentally, the agglutinative activity of his serum increased from a reaction obtained in a 1:320 dilution to a reaction in a 1:2500 dilution. The best success in the isolation of the organism from the blood has been secured with material from persons who were severely ill. Probably the bacteria are relatively few in number in the blood of ambulant patients. Another difficulty in the isolation of organisms from the blood is that freshly isolated cultures develop slowly on artificial media, from one to three weeks being required for colonies to appear. Plates kept in closed jars for this length of time not infrequently become contaminated with molds, which of course renders them useless for further study.

Less success has attended efforts to isolate cultures from urine than from blood. A few authors[1, 4, 5, 14] have reported the isolation of *B. abortus* from the stools of several patients having undulant fever. From the reports of autopsy findings, however, one would not expect a large percentage of cases to have a very exter volvement of the intestines. Bruce[15] i after his wide experience with the di Malta, considered the finding of ulcers intestinal mucosa in one case, to be sul important to describe. He mentions in f the absence of such lesions in these patie used as a factor in differentiating Malt from enteric disease.

Skin tests corresponding to that of v quet for evidence of tuberculosis have b posed, but cannot at present be recom owing to the severity of the reactions obtained with preparations of *B. aborti* the patient has undulant fever. It is ho further study of the problem will per selection of extracts which will be entir able for this purpose.

A blood count usually indicates a se anemia and leucopenia with a relative inc the percentage of mononuclear cells. Thi mation is helpful when abdominal surgery sidered. The localization of pain and ter in the abdomen in some cases of undula has apparently led to appendectomies an operations. Such patients seem to be poo cal risks. You may be interested in an which has come to our attention. A wo 62, after an illness of about two weeks wi ache, edema, dyspnea, and vomiting after had a cholecystectomy performed and li two weeks. The gall bladder was repo have shown evidence of subacute chole Her hemoglobin was said to have been cent; the red blood count, 4,230,000; white blood count, 8,400, of which 58 were neutrophiles. A specimen of blo lected on the date of operation gave no in the complement-fixation test for syph the serum in a dilution of 1:5000 defini glutinated *B. abortus*. A reaction of such sity indicates quite conclusively that the had undulant fever. Whether the inflan of the gall bladder was due to *B. abortus* other species of bacteria could only hav determined by bacteriological study. A tioned previously, the literature indicates ganisms of the abortus-melitensis grou been isolated from the bile of patients with lant fever. Such cultures are frequently in the gall bladders of guinea pigs that h veloped the infection after intraperitoneal lation.

In conclusion, as long as milk and cre used without pasteurization, cases of u fever will probably continue to occur. I indicate that a fairly large percentage o in New York State have the disease, a much of the milk in rural districts is use Consumers, including people on vacation country, are thus exposed.

STRAMONIUM IN CHRONIC EPIDEMIC ENCEPHALITIS

Report of its effects on sixteen Parkinson and four choreoathetoid cases.

By PATRICIA STEEN, M.D., KINGS PARK STATE HOSPITAL, KINGS PARK, N. Y.

ACCORDING to the U. S. Dispensatory,[1] stramonium is so similar to belladonna in dosage, toxicity and general action that the two drugs are practically identical, and the former has been employed in all the conditions for which the latter is more commonly used. Stramonium, however, acquired special repute in the treatment of asthma following the introduction into Great Britain of datura ferox from the East Indies, and up to the middle of the present decade the drug was chiefly used for this disorder. Its use in nervous and mental disease had been recognized as early as 1797 by Samuel Cooper,[2] who used the drug, datura strammonium, in the treatment of mania, epilepsy and certain fevers, but in our time, stramonium was apparently not used to any extent in the treatment of neurological conditions until recent years. In 1925, Juster[3] demonstrated the definite value of stramonium in the relief of Parkinson rigidity. Following Juster's communication, the same method of treatment (i.e., with datura stramonium) was successfully carried out by Laignal-Levastine and Valence[4] in 1926, and by Shapiro[5] in 1928. These writers reported improvement in all symptoms. They noted diminution or abolition of rigidity and tremor, and marked improvement in the mental attitude of the patients. Harris[6] appears to have been the first to have used the tincture of stramonium. In 1927 he treated a group of Parkinson cases with 25 minims of the tincture, three times a day. He did not feel that his results were encouraging, but more recent workers have expressed the opinion that Harris' dosage was too small to produce the desired reaction. In 1928, Carmichael and Green[7] found that large doses of the tincture (45-60 minims three times daily) decreased the Parkinson rigidity and produced improvement in the performance of fine movements, though the tremor was not affected. Jacobson and Epplen,[8] in 1929, checked the observation of the last named writers. In a series of 23 cases, six of which were reported in detail, they noted marked improvement in all symptoms of post-encephalitic Parkinsonism except the pareses, under tincture of stramonium in doses ranging from 20 to 70 minims three or four times a day. Muscular rigidity, often of high grade, was eliminated or lessened, so that the patients could dress, walk more loosely and swing their arms in doing so. Fatigability, myalgia, dysphagia, ptyalism and tremor were also lessened or eliminated, and bradykinesia was always strikingly improved.

Hoedemaker and Burns[9], in a series of thirty-one cases, twenty-seven of whom showed the paralysis agitans syndrome following epidemic encephalitis, found that the maximum dosage necessary to obtain the best results varied between 60-90 minims three times a day. With these amounts striking improvements were noted. Four patients previously completely bedridden became able to get out of bed unaided, to walk easily without falling, to feed and dress themselves. One patient who had been bedridden for at least a year was able to sew and to play a selection on the piano. Three patients were discharged and

returned to work. All patients showed complete relief from excessive salivation. Sixteen patients showed varying degrees of diminution of rigidity, and increase in ability to perform fine movements. Five patients did not show definite improvement in physical signs, but felt more comfortable. In six patients no definite change, except relief from excessive salivation, could be noted. These writers point out that the toxic effects from large doses of stramonium are rarely severe, and can be readily combated. This point had previously been emphasized by others.[7,8]

Report of Series

From a large group of post-encephalitic Parkinson patients six men, six women, four girls and four boys were chosen as those most in need of relief of symptoms. In searching the literature we could find no record of the use of stramonium on post-encephalitis cases other than Parkinson types. As hyoscyamine, the chief constituent of stramonium, has been described as a sedative to the central nervous system and a paralysant of nerve endings, it was felt that it might benefit three boys and one girl whose constant restlessness, tics and choreoathetotic movements made life very uncomfortable, and these four were added to the list, making a total of twenty who received the medication. The ages of the patients ranged from 9 to 28 years and the duration of the symptoms varied from 5 to 12 years. The U.S.P. tincture of stramonium was used. Each case was started in a dose of 20 minims three times daily. This was daily increased by one minim per dose. If symptoms appeared the drug was discontinued and one day later was re-instituted at the previous dose, and increased as before up to the limit of tolerance. The lowest dose tolerated was 35 minims three times a day, the highest was 110 minims four times a day and the average lay between 75 and 85 minims three times a day.

Results on Symptoms and Physical Signs

The non-Parkinson patients failed to show any improvement, and one indeed seemed distinctly worse, but results in the Parkinson cases were very encouraging. The drug seemed in almost all the Parkinson patients to produce its maximum effect when the limit of tolerance was first reached, and for about one month afterwards. Subsequently, the improvement was less marked, though in most cases was still noticeable. Two of our moderately advanced Parkinson women have been kept fairly active and relatively comfortable for a year, whereas, before treatment they were greatly disabled, whining and depressed. Although it is obvious that no definite statement can be made, it has seemed that the rate of increase of the rigidity and general disability was slowed in the Parkinson cases treated. This opinion is based on observation and comparison of the patients treated, with a similar group of untreated controls. However, all cases showed eventual down-hill progression, and no permanent improvement was noted in any case. After the drug was discontinued its effects rapidly wore off and in a week or less the patients had relapsed to their former state.

Rigidity: Sixteen of our patients showed this in marked degree, and were greatly benefited while under medication, and with this, great improvement in the ability to perform fine movements was noted. Four patients who had been helpless for nearly a year, became able to feed and dress themselves, to move about the ward, and to play such games as dominoes. The others were noted to walk more easily, could run more readily, and in four cases showed some return of a previously absent arm swing. All sixteen said they felt much more comfortable, and appreciated the fact that they could move more quickly and do more with less fatigue. Two patients said they were especially pleased because they could hold their mouths closed, and one boy with a troublesome dysphagia which had led him to refuse all but liquid nourishment, became able to swallow any food provided.

Propulsion and retropulsion: These were lessened but not eliminated in any instance. One boy, R. S., aged 13, showed improvement of his peculiar and very hampering gait. He was unable to take more than six steps forward without making a sort of waltzing turn to the left, frequently falling to that side. Under medication he was able to take as many as thirty forward steps without the dancing motion, and he no longer fell, though his steps remained short and of the propulsive type.

Tremor: All of the sixteen Parkinson type cases showed this in varying degree. In two the tremor seemed entirely eliminated by stramonium. In the other patients the tremor was decreased from fifty to seventy-five per cent, except in three cases when the tremor was unaffected.

Ptyalism: Six patients complained of this, and expressed complete relief while under treatment.

Respiratory disturbance: Three of the Parkinson group were subject to attacks of tachypnoea. and one boy in whom the condition was associated with cyanosis seemed distinctly benefited. The other two showed no improvement while receiving stramonium. The grunting and hissing respiratory disorders of two chorea-athetoid cases were also unchanged.

Tics and choreiform movements: Four children troubled by involuntary movements of different degree received medication. None showed any improvement and one boy seemed distinctly worse. Previously he was at rest part of the time, but while taking tincture of stramonium, 35

minims three times a day, he became a dynamo of purposeless activity, seemed quite unable to sit or stand still for a minute. His old facial tics became more frequent and severe, and he developed new choreiform movements of the hands. When the stramonium was discontinued he rapidly returned to his former state.

Convulsions and oculogyric crises: Three Parkinson patients subject to convulsions showed no reduction in frequency of this phenomenon. Of five patients suffering from oculogyric crises, two showed benefit in that the crises occurred less frequently and were of shorter duration.

Mental condition: All of the Parkinson group seemed more alert, answered questions more promptly, and were happier and more contented. One girl subject to frequent outbursts of noisy weeping became more stable and cheerful as she became able to get about and to occupy herself to some extent in reading or looking at picturebooks. No improvement was noted in mischievous or impulsive tendencies. One girl continued to assault without any provocation those to whom she seemed most attached, although she was much improved physically.

Of the four choreo-athetoid patients two realized they were more restless and uncomfortable but otherwise this group showed no mental change.

Toxic Effects

None of the patients suffered from loss of appetite, nausea or vomiting, and though several commented on the dryness of the mouth, this was not troublesome in any case. Three patients complained of dizziness but this disappeared after omission of three doses and did not reappear. Blurring of vision occurred in several cases as the limit of tolerance was approached. In one patient, aged 13, the dose had to be restricted to 45 minims, three times a day, because of this disturbance.

Two patients complained of an itching of the skin, and one showed a mild urticarial rash which disappeared when the drug was omitted, and did not recur when administration was resumed.

Conclusions

1. Tincture of stramonium in suitable doses seemed of great benefit in alleviating the forced inactivity and discomfort of sixteen cases of post-encephalitic Parkinsonism.

2. In four post-encephalitic cases of the choreo-athetoid type this drug had no beneficial effect, and seemed to aggravate the symptoms of two patients.

3. In the children and young adults observed, the average tolerance of stramonium was high, and the drug caused no serious or lasting toxic effects.

4. In the Parkinson cases the drug seemed to slow the rate of increase of the disability, but did not in any case arrest the progress of the disease.

THE POLIOMYELITIS SITUATION

The poliomyelitis epidemic continues at about the same pace that it has maintained during mid-summer. The center of the disease is New York City, with the surrounding counties showing an incidence diminishing with their distance from New York. The attitude of the family physician toward the epidemic continues to be most commendable. County medical societies have taken the lead in promoting the education of both the physician and the people; and their members are cooperating with departments of health of the State and the local municipalities, and with the local health organizations.

THE STATE MEDICAL JOURNALS

The peculiar function of the official organ of a state medical society is to record the activities of that society and those of its component county societies. The original object of the State societies was almost entirely scientific. They confined their activities to promoting a knowledge of human diseases and their cure. They dealt with the relations of an individual doctor to an individual patient, and entered only slightly into the great field of preventive medicine. But in recent years state medical societies have gradually adopted the second object, that of administrative medicine, or the development of means by which doctors may cooperate with official bodies and lay organizations in bringing medical service within the reach of all persons. The state journals find their special fields in recording what the medical profession is doing along the lines of administrative medicine. Yet, the scientific articles of the state journals are about all that receive notices. While the medical societies are promoting the practice of administrative medicine to an extent that is not generally recognized in current health literature, there is an immense amount of public health literature recorded in the popular health journals and in the health departments of the daily and weekly press, and by the radio; and in all this publicity the medical societies of the states and counties are practically ignored.

State societies are entering administrative fields which were formerly occupied solely by departments of health and volunteer health organizations. The medical profession has asserted its leadership in all these lines of work during the last five years, and possibly the time has been too short for the general recognition of the literature of these activities.

The editors of the NEW YORK STATE JOURNAL OF MEDICINE have attempted to study all that the several state societies are doing in administrative medicine, because the members of the New York Society are assuming the leadership in all branches in the practice of administrative medicine and wish to know what the other state societies are doing. The Editors made their work available by instituting a system of abstracting the records gleaned from the other state journals, and publishing them in a department called "Our Neighbors." This department is the most complete of all the records and indexes of what the several state medical societies are doing. Ten per cent of the Journal is given to this department. Any one looking through the annual index of this department can obtain a fairly complete idea of what the several state societies are doing in the various lines of public health, such as anti-diphtheria campaigns, popular medical publicity, radio talks, child examination, and the relations of physicians to the workers in the voluntary health organizations.

A recent incident illustrates the value of the department of "Our Neighbors." A research worker looking up the literature referring to graduate education had accumulated about a hundred or more references going back for ten years. But practically none of the references referred to the activities of the medical societies of the states and counties. Even the Journal of the American Medical Association was found to have records only of scientific articles that are published in the state journals, and the Index Medicus practically ignores the activities of state societies. The research worker had not run across the department of "Our Neighbors" in the NEW YORK STATE JOURNAL OF MEDICINE because none of the items had been listed in any of the references available in one of the largest medical libraries. Yet last year the activities of eleven states in graduate education had been recorded in this department. The references in the NEW YORK STATE JOURNAL OF MEDICINE for three years added more than twenty-five per cent to the number of references which the worker had been able to find from other sources. Furthermore, it broadened the field of graduate education to include the participation of the general membership of the State and county medical societies.

There are three reasons that the administration activities of the medical societies are not generally known:

1. The active participation of the medical societies in administrative fields is so recent that publicity writers, following the older lines of reporting, have not appreciated the importance of the newer attitude of physicians.

2. The number of articles on administrative medicine put forth by medical societies is small in quantity compared with that issued by lay organizations having paid publicity staffs.

3. The literature approved by medical societies is conservative and lacks the unqualified promises of one hundred per cent effectiveness that are often claimed by lay health writers.

A new movement in medicine is of importance in the proportion in which it may be adopted by medical organizations elsewhere. The records abstracted in the department of "Our Neighbors" are of activities which have a universal application wherever scientific medicine is recognized and practiced.

EXPERIMENTS ON HUMAN BEINGS

If there is anything for which the medical profession is feared, it is that human beings will be used as subjects of "experiments" by doctors.

On the other hand, if there is anything for which the medical profession is criticized, it is that doctors refuse to "try" new remedies that are announced in the daily press.

Medical editors are besieged with requests for aid in securing the cooperation of a doctor or hospital for the trial of a new treatment of some disease. This very editorial was inspired by a visit from a young man who thought himself cured of hayfever by a new inhalant; and he wished to announce his cure for the benefit of humanity. He was told kindly and courteously that doctors do not "experiment" on persons; and that the Rockefeller Institute and similar organizations existed for the purpose of conducting researches into new medical procedures. The man was honest, and was grateful for the information.

The people generally are quite willing to try medical experiments on themselves, and they believe the alluring stories of the curative effects of nostrums advertised to restore sufferers to health "after the doctors have given them up." But let a doctor "try" the remedy unsuccessfully, and his patient starts a suit for malpractice.

It is hard for the people to understand the attitude of the medical profession toward a doctor whose claims to have discovered a new method of treating a disease are announced through the newspapers. The medical journals as well as the daily press recently carried accounts of a hearing conducted by the New York State Board of Charities on the application of two physicians to establish an endowed hospital in which to demonstrate the effects of a new agent upon persons suffering with advanced cancer. The medical profession heartily approved the denial of the application. While physicians are progressive and apply new methods to cases which they have studied thoroughly, yet they strenuously object to the application of any one remedy to every case of a disease.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

Vacation Accidents:—This Journal of September, 1906, discusses vacations editorially, and explains their dangers on grounds that are thoroughly modern. The writer says:—

"The mistake made by our summer vacationist is to plunge into vacation with the confidence of vocation; and in these strenuous days there is too wide a distance for safety between the two.

"The insanity of amusements of our seaside resorts does not give recreation. Most of the patrons of Coney Island find themselves worse off for it on Monday morning. It involves more nervous strain and excitement than exists in their every-day work, and many more dangers, as experience has shown.

"Thousands of employes work hard all the year, and have a vacation of two weeks in July or August. This vacation is an event, and well it should be, for their labors have earned them two weeks many times over. It is prepared for and thought about, and a good time must be had at any cost: The 'good time' too often consists in endeavoring to crowd into that short space a succession of events, which should have been distributed more equably through the year. The vacationist works more strenuously at having a good time than he does at earning his livelihood.

"All of these conditions cause an approach to the danger line in vacation time; and behind it all lies the strenuous life. The average American, who is fighting his way to business success, does not know how to play or to take recreation.

"There is little that the law can do. It is not a matter of throwing more safeguards about the people, as is suggested. The defect is manifestly a fundamental one, and lies in our socio-economic conditions."

MEDICAL PROGRESS

Chemotherapy in Cancer.—In making out his case in favor of chemotherapy, W. Blair Bell states that a local "cure" of cancer by surgery or irradiation by no means implies that the patient is safe from dissemination of the disease throughout the body. Furthermore, in at least three-fourths of the patients who die of cancer the disease is too far advanced before it is recognized to be suitable for local treatment. There are, therefore, investigators who still think it worth while to persevere in the field of chemotherapy. In this field the author has made a special study of chorionic epithelium, with the finding that lead appears to exert an almost specific destructive effect on this type of tissue. He reminds the reader, however, that a chemotherapeutic product which will cure cancer in animals may be ineffectual in, or poisonous to, the human subject. During the past fourteen months he has worked with the Brown-Pearce transplantable epithelioma in rabbits, supplied by W. P. Graves and George Van S. Smith of Boston. This rapidly metastasizing growth untreated is inevitably fatal, the average duration of life without treatment being about twelve weeks. An organic preparation, H_{126}-benzenesulphonylglycinate, prepared in Professor Heilbron's laboratory, gave most dramatic results when injected intravenously in animals with widespread metastases, and one animal was still alive twelve months later. Because of its toxicity, it is impossible to use the preparation intravenously or intramuscularly in the human subject. Recently, W. A. Collier of the Koch Institute has assured the author that in lead we have the only known element that specifically affects cancer, apart from local radiations, and that he also has found the Brown-Pearce rabbit tumor satisfactory in respect of certainty of positive implantation and fatal outcome. Collier also states Rothmann, has prepared a water-soluble, diffusible organic compound in which the lead is not ionized, and which remains unaltered, as has been proved chemically, in the tissues when injected locally—a difficult thing to understand—and is slowly taken up in this state, without any toxic, but with a curative, effect on the malignant neoplasm of rabbits in 80 per cent of all cases. Fournier has for several years used injections of fumarate of lead in cases of cancer in which the tumor was inoperable or inaccessible to *x*-ray or radium treatment. He has never observed injurious effects, and has had very encouraging results, many patients having been cured and the cure having been maintained for more than two years. Bell states that he has seen more than enough to realize that in many cases treatment with lead offers the only possibility of, and frequently secures, beneficial results. He firmly believes that a course should always be given to patients after operations for malignant disease.—*Practitioner*, August, 1931, cxxvii, 2.

The Treatment of the Gastrocardiac Syndrome (Gastric Cardiopathy).—The expression "gastrocardiac syndrome" was coined by L. Roemheld, in 1912, to characterize those disturbances of the circulatory system, and particularly the heart, which are produced by faulty function of the digestive tract, particularly the stomach. Such disturbances are due to one of two cases: (1) Mechanical, from dislocation of the heart and large vessels due tc elevation of the left half of the diaphragm as a result of subdiaphragmatic accumulation of gas, such as may be caused by various functional or organic anomalies; (2) reflex, through the effect of chemical and toxic substances within the stomach and intestine. The basis of successful therapy must needs be the discovery of the specific cause of the subphrenic air bubble and the removal of the accumulated gas. The cause of the gas may be aërophagy, insufficient absorption of gastric or intestinal gas and delay in its expulsion, or increased formation of gas caused by abnormal fermentation and decomposition of unsuitable food in a gastrointestinal tract whose chemism is disturbed. Treatment must first be applied to the psychic and general condition of the patient. He must be assured that his heart is perfectly normal and that it is only his dyspepsia which needs attention. In the treatment of the digestive apparatus all gas-forming foods which contain much cellulose must be excluded. Overeating should at all times be avoided. An occasional change from a vegetable-carbohydrate to a meat-fat diet sometimes yields astonishing results. A mild form of exercise is better than rest after eating, and abdominal massage is of importance. In the medicinal treatment of subacidity or anacidity pepsin combined with hydrochloric acid gives excellent results. Hyperacidity requires atropine or any of the numerous antacids. Not infrequently a gastric lavage produces magic effects. None of these measures has a lasting effect unless it is supported by physiotherapeutic procedures. The purpose of these is to accelerate venous circulation in the abdominal cavity and thereby reduce the accumulation of gas. Abdominal massage, gymnastics, sitzbaths, half-baths, nightly moist compresses, etc., are employed. Of equal importance is training in diaphragmatic breathing, which is identical with the abdominal type of respiration. These procedures carried out for a sufficient length of

time yield excellent results in most cases. The measures recommended for the purely functional gastrocardiac syndrome apply also to cardiac patients, in addition to therapy directed to the heart condition.—*American Journal of the Medical Sciences,* June, 1931, clxxxii, 1.

Origin and Treatment of Chronic Constipation.—Hans Wantoch says that it has been customary for many years to maintain that disturbance of gastric secretion is responsible for certain cases of constipation, but that this causal connection has been pointed out almost exclusively in cases where there has been an increase in the amount of hydrochloric acid and in the degree of acidity, while hyperacidity and anacidity have been held to account for so-called gastrogenous diarrhea. Wantoch has had occasion in a series of cases to observe what seems to be a causal relation between hyperacidity or anacidity of the gastric juice and constipation. It is a familiar fact that gastric anacidity is attended almost uniformly by a significant rapidity of emptying of the stomach, and that the food-mass then very often runs rapidly through the intestine and far into the colon. Hence it is the more remarkable that the fact has been established that, despite this speed, diarrhea has been the result in only a small proportion of cases, and that in some of the remaining cases constipation was the outcome. Four personal cases are cited to emphasize this statement. Dilute hydrochloric acid was prescribed in all, 8-10 drops in a glass of water, to be taken in sips during the course of each meal. All the patients were promptly relieved of their constipation. In 3 of the cases the hyperacidity or anacidity had expressed itself not only in constipation but also in gastric disturbance after eating. To prove whether the effect might not be equally good in cases without gastric symptoms, in which constipation was the only complaint, the fourth patient was given the same treatment. This was a woman of 50 who had suffered with constipation for many years, but complained of no other disturbance. After a test meal there was found free hydrochloric acid 10, total acidity 18; microscopic findings, negative. Administration of hydrochloric acid promptly relieved her condition. The author believes there is more frequently constipation than diarrhea as the result of lack of hydrochloric acid, and urges that his findings be put to the test by others in order to obtain more data on the subject.—*Münchener medizinische Wochenschrift,* May 29, 1931.

Pulmonary Congestion as a Form of Grippal and Toxinfectious Pulmonary Affection.—P. Kaczander and B. Rudin say that in their experience during the grip epidemic of 1930-31, very few cases were followed by lobar pneumonia, bronchopneumonia, or bronchitis, but that nearly all exhibited a pulmonary process which does not fall readily into any of the usual clinical categories. In their cases there was a so-called grippal general infection which was followed by a toxic injury of the pulmonary vessels and by affections of the lungs to which French clinicians have given appropriate names, and which are known in Germany as "moist lungs," "engorgement," and "one-day pneumonia." The essence and the beginning of the pulmonary congestion is, accordingly, an inflammatory active hyperemia of the alveolar capillaries. From the inflammation, as it progresses, various forms of pulmonary congestion are derived. If the advance is toward the lumen of the alveoli, there are epithelial desquamation, exudation of serofibrinous fluid, diapedesis of red, and even more of white, blood cells, resembling the stage of engorgement in croupous pneumonia. Thus we have the picture of an alveolar catarrh, closely analogous to the catarrhal inflammations of other serous or mucous membranes. In most cases there is no persistence of this stage. The affection progresses either toward the lumen of the alveoli—assuming the form described by Voillez, related to pneumonia—or else outward to the pleura, leading to the pleuropulmonary form described by Potain. If it goes in both directions we have the "pulmonary flux" of Dupré and Grasset, and of Dieulafoy. During the 1930-31 epidemic a striking feature was the profound subjective sense of illness in the presence of relatively slight objective signs. There was a marked predominance of catarrhal symptoms in the air passages. The pulmonary findings scarcely fitted into any of the classical forms of bronchopneumonia, bronchitis, bronchiolitis, etc., with or without participation of the pleura. Instead there were varying nonlocalized objective physical symptoms, such as lightening of the sounds over the affected parts, which almost never amounted to dullness. In most cases the pneumococcus was the exciting agent, but frequently there was a mixed infection of staphylococcus, streptococcus, and pneumococcus. The unknown grip virus must in reality be regarded as the primary agent, taken together with other toxinfectious possibilities.—*Deutsche medizinische Wochenschrift,* May 29, 1931.

The Late Sequelae of Encephalitis Lethargica and Influenza.—Charles Hunter, writing in the *Canadian Medical Association Journal,* June, 1931, xxiv, 6, emphasizes the fact that with the passing years the disastrous consequences of encephalitis lethargica have be-

come only more apparent. Like syphilis it may remain active for years within the nervous system, causing by recurrent outbursts, by slow inflammatory lesion, or by gradual disappearance of nerve cells in the basal ganglia, increasing disability to the patient. Usually the more severe the initial stages the more serious are the after-effects. Economo estimates that for all clinically well developed cases the mortality is 40 per cent, recovery takes place in 14 per cent, while in 26 per cent recovery is sufficient to permit the patient to return to work, though some defect persists. Chronic invalidism results in 20 per cent of the cases. The figures of the British Ministry of Health show that 50 per cent of those attacked by the disease suffer from sequelae, and a half of these develop the Parkinsonian syndrome. Second in importance to the Parkinsonian syndrome are the mental changes with marked alterations in character and conduct. Ocular defects are common. Obesity and polyuria occasionally develop, and respiratory sequelae may occur. All methods of treatment have been considered most discouraging. Economo recommends, even in the chronic stages of the disease, Pregl's solution, or 10 per cent sodium iodide solution (100 c.c. intravenously once a week for ten to fifteen weeks). Other remedies endorsed by individual physicians are acriflavine and 2.5 per cent solution of sodium salicylate. The author believes there is no question of the value of hyoscine in relieving the stiffness and tremor, and making the patient more comfortable. The drug may be used for years with safety and does not seem to lose its effect. Beginning with 1/500 grain twice a day, the dose is gradually increased to two or three times this amount. Intractable insomnia is sometimes helped by the intramuscular injection of 2 c.c. of milk; sun baths, light baths and massage have their place in particular cases. Encephalitis lethargica probably bears no relation to influenza, as has been thought by some physicians. In the latter disease the respiratory tract bears the brunt of the acute attack and is the site of the leading sequelae. Tuberculosis is sometimes aggravated by influenza, but there is no statistical evidence to show that it has caused an increase in the number of cases. Occasionally heart symptoms occur for months after influenza, but it is remarkable how little the heart is permanently damaged by the disease. Neurasthenic symptoms often prolong convalescence for months.

Blood Potassium and Malignant Tumors.—In view of the contradictory results reported by other investigators Corradino Giacobbe undertook experiments to determine whether or not there is an increase of blood potassium within the tissues of malignant tumors. He found in every case an increase, observable in all forms of malignant neoplasms, but particularly in those of the epithelial tissues. The amount of excess potassium in the blood of these tissues is proportional to the state of activity and of evolution of the neoplasm. After such a tumor was removed, the blood potassium always dropped to a lower figure. In some cases for the sake of greater accuracy the author repeated the test twice and then used the medium value found. The method utilized was the classic procedure of Kramer and Tisdall, based on precipitation of potassium in the form of cobalt-nitrite of potassium, and for the determination of the latter, after it was freed from excess of the reagent, he used a titrated solution of permanganate, neutralizing the excess of permanganate with excess of oxalic acid, and then liberating this last excess anew with permanganate until the solution assumed a persistent pale rose color. The potassium, which is a normal component widely diffused in the organism, was found to have a concentration 10 times as great in the red corpuscles as in the plasma. The values found in the blood of normal individuals varied from 17.48 mg. to 30.24 mg. per 100 c.c. serum, with an average value of about 24 mg. Of 12 individuals suffering with various morbid affections of a noncancerous nature, an excess of potassium was found in only 1, a patient with hemolytic icterus. Of 8 persons having benign neoplasms, only 1 suffering with a fibrolipoma of the thigh had an excessive amount of potassium. On the contrary, in a group of 24 patients having malignant neoplasms the blood potassium was found constantly elevated. In every instance in which a malignant tumor was removed, the blood potassium fell after the operation, such fall being demonstrable within 10 days after the operation and becoming more marked as the time increased. Although the study of the blood potassium reveals no specificity and has no important clinical value, the behavior of this substance constitutes an index that should not be ignored with reference to prognosis—one that becomes more striking pari passu as the development of the tumor is more rapid.—*Riforma medica,* May 18, 1931.

The Value and Limitations of Sodium Amytal.—In this paper N. S. Clark confines his remarks to the intravenous administration of amytal (sodium iso-amyl-ethyl salt of barbituric acid). He states that the dose varies from 6 to 35 grains, and averages from 8 to 20 grains. With less than 15 grains, however, there is seldom the complete relaxation necessary for surgical operations. The *advantages* of amytal anesthesia are: (1) Quiet induction, there being no stage of excitation, and thus the patient is spared a great deal of pre-operative apprehension; (2) there is no post-operative vomiting; (3) it greatly

facilitates the administration of nitrous oxide, ethylene, and ether, and the amount of these anesthetics is greatly reduced; (4) it produces no kidney irritation; (5) it does not appreciably alter the carbon dioxide combining power of the blood; (6) it produces no irritation of the respiratory passages, and is therefore a safe anesthetic in lung cases. Sodium amytal has been used with success in persistent hiccough, and for the pruritus of jaundice in which a dose of 4 grains intravenously arrests the itching for four hours. It is also useful as an antispasmodic in strychnine poisoning, tetanus, gastric crisis, rabies, epilepsy, renal colic, gall-stone colic, and eclampsia, as well as in asthma, delirium tremens, pernicious vomiting of pregnancy, and severe migraine. It greatly lessens the toxicity of procaine and cocaine. The *disadvantages* of sodium amytal are: (1) The long period of time required for the patient to become conscious, thus necessitating more nursing care; (2) inability of the patient properly to raise mucus; (3) the fall in blood pressure, normally 20 to 30 mm. Hg., but often greater; (4) the difficulty of gauging the proper dose; (5) occasionally the difficulty of entering a vein in which to inject the sodium amytal. Also if any of the solution should enter the tissues, it will produce a sore arm and possibly a slough. Sodium amytal is suitable for narcosis, for light anesthesia, and for a basal anesthetic, but alone it is not satisfactory for deep anesthesia.—*Canadian Medical Association Journal,* July, 1931, xxv, 1.

The Etiology of Anginas with Mononuclear Reaction.—In the belief that there might possibly be etiological relations between Plaut-Vincent's angina and angina with mononuclear reaction, U. Friedmann and A. Elkeles made a study of 16 cases of the former, by which they were able to show the great value the mononuclear reaction may attain in this disease. The cases show from 20 to 81 per cent of lymphocytes and monocytes, only one individual having less than 29 per cent. These figures equal those in anginas with mononuclear reaction, so that it is impossible to distinguish the two diseases on the basis of the blood picture. The response to therapy gave still further support to their identity. It is well known that Plaut-Vincent's angina reacts specifically to treatment with neosalvarsan. All the cases responded promptly and were free from fever in from 24 to 48 hours. The authors then gave the salvarsan treatment to certain cases of mononuclear angina in which spirilla and fusiform bacilli were not found. The results were completely negative. Hence it seems indisputable that in the authors' cases the spirilla and the fusiform bacilli were really the exciters of the mononuclear angina. They therefore came to the conclusion that some of these morbid conditions—in their material more than half—are identical with Plaut-Vincent's angina in their etiology. It is self-evident that if the two diseases have an identical etiology, no distinction between monocyte angina and Plaut-Vincent's angina is possible, in principle. Hence the authors incline to believe that the mononuclear anginas with positive Plaut-Vincent findings are only especially severe forms of Plaut-Vincent's angina. They regard it as most probable that anginas with mononuclear reaction may be divided into two classes, thus far indistinguishable clinically, but different etiologically, one of which is identical in etiology with Plaut-Vincent's angina and is to be regarded only as an especially intense reaction to the infection with spirilla and fusiform bacilli. Between angina with mononuclear reaction and Plaut-Vincent's angina there exist relations similar to those between varicella and herpes zoster. —*Deutsche medizinische Wochenschrift,* June 20, 1931.

A Case of Multiple Sclerosis Treated by Hyperpyrexia.—In the case of a young woman of 22 on whom a wide diversity of treatments had been tried unsuccessfully, H. Christy says that he has had decidedly encouraging results from the use of antichancroid vaccine with its consequent hyperpyrexia. The patient had exhibited nervous symptoms since she was 14 years of age, which gradually became more marked. At the time the diagnosis of multiple sclerosis was made, the neurologic symptomatology was very typical: diffusion of pyramidal excitation, with negative findings in spine and cerebrospinal fluid, and absence of objective sensitive symptoms. The patient could no longer walk nor hold herself upright. The author, not having available any case of unmixed malaria, was loath to use vaccine from a case of general paralysis upon a nonsyphilitic individual. He therefore proposed a substitute form of hyperpyretic therapy, namely intravenous injections of antichancroid vaccine, which the patient accepted. She received 7 injections at intervals of 3 or 4 days, the doses being 115 millions of Ducrey's bacillus, then 120, 300, 500, 550, 600 and 650 millions, with resultant temperatures of 39.4°, 38.8°, 40.2°, 39.9°, 40.3° and 40.1° C. The treatment was well tolerated without any disadvantageous incidents. Marked improvement was soon evident; the patient began to walk again, at first slowly, then more nearly normally; at the present time, although very spastic, she goes and comes, and says of herself that she is another being. The interpretation of the case is difficult. In a disease of such long, slow evolution, it is not easy to judge of the action of a treatment. The author used small doses because the patient was a woman, for he has found that women do not tolerate such large doses as men. He intends to apply the same treatment in other cases of multiple sclerosis, and will publish the results, whatever they may be.—*Journal de médecine de Lyon,* June 20, 1931.

LEGAL

PHYSICIAN AND PATIENT—OPERATION UNDER MISTAKE AS TO IDENTITY

By LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

The courts in our Western States have been called upon to pass on two cases of great interest to physicians. The lawsuits in question concern themselves with treatment rendered by a physician to the wrong patient. Cases of this character fortunately are rare, but they serve to illustrate the care that the physician must take in order that treatment may not be given by the physician to the wrong patient.

In the first of these cases the facts are briefly as follows: The plaintiff, a woman, consulted two doctors who were associated together in the practice of their profession, for the purpose of having a thorough physical examination made including a blood test. The examination was made and she was instructed to return a week later for the report of the examination. Another patient, upon whom a spinal puncture test was to have been made, had an appointment for the same hour. When the plaintiff returned at the designated hour, she waited in the reception room until a nurse employed by the doctors, without addressing her by name, told her to "come on." The patient followed the nurse and asked what was to be done and was told, "Oh, that is nothing, we are going to give you a test something like a blood test." The patient removed her clothing, was wrapped in a sheet and asked to get on the operating table, and was told that Dr. M. would perform the operation. She had no knowledge of what was to be done, but merely complied with instructions. The doctor made a spinal test in the usual manner, withdrawing a small quantity of spinal fluid by means of a hypodermic needle.

The plaintiff learned that the test had not been intended for her but for the other woman, and instituted suit against the two doctors for the sum of $15,000 for compensatory and punitive damages, claiming that as a result of the test made erroneously and without her consent she suffered great physical and mental pain, severe headaches, nausea and pains in her legs. Upon the trial of the case the plaintiff made no contention that the test was done in an improper manner. The defendants frankly conceded that the test was not intended for the plaintiff and that it was not necessary in her case, but was performed through "carelessness of the assistants in the office." A verdict was rendered by the jury in favor of the plaintiff for $6,250.

An appeal was taken on several grounds. It was contended that the plaintiff consented to the spinal puncture. The appellate court ruled that such an argument was not properly made to them as the jury had decided the facts to be otherwise, and it was unreasonable to interpret the facts as amounting to a consent as a matter of law. On this point the court said:

"The argument that she consented to the spinal puncture does not appeal to us. Neither did it to the jury. Most patients place implicit confidence and trust in their physicians. They do what they are told to do. Questions by the patient are usually not in order. There is evidence that the plaintiff did not know the nature of the test to be performed. If such is true how could she have given consent?"

The court in deciding the appeal ruled that a case of liability entitling the plaintiff to damages for negligence had been established, but sent the case back for a new trial on the ground that punitive damages sometimes known as "smart money" had been included in the verdict which it ruled improper in such a case.

The fact situation in the second case was fairly similar, although it differed in the essential that the defendant doctor did not freely admit that an error had been made. The plaintiff was a young man who attended a state normal school. He suffered eyestrain and consulted Dr. P, an eye, ear, nose and throat specialist of excellent standing, for the purpose of having his eyes examined. On the occasion of his first call at the doctor's office, certain tests were made and the patient was informed that to accomplish a thorough examination dilation of the pupils would be necessary. The patient requested that that be not done at that time and obtained an appointment for the next day. The patient appeared for treatment at the appointed time and the nurse sent him into the doctor's office. According to the testimony of the plaintiff, Dr. P. invited him to sit down in a chair different from the one he had occupied on the previous visit and the doctor, without asking any questions, proceeded to wash out plaintiff's right antrum after applying a local anesthetic. After this was done, according to the patient's story, he overheard the doctor state to his nurse that he was expecting "that young fellow from the normal school." At this point the patient stated to the doctor that he was S, the normal school student, and the doctor thereupon exclaimed, "Gosh, I thought your name was G." The doctor then directed the young man to an-

other chair where he completed the eye tests and concluded that glasses were unnecessary. The plaintiff claimed that the doctor said to him in a joking manner, "At least we known your antrum is clear."

Thereafter the patient brought suit against the doctor claiming that, due to the treatment administered to him without his consent, he became ill and suffered great pain in his head and another surgeon treated his antrum, draining therefrom a quantity of infected matter. The plaintiff further claimed that a subsequent confinement in a hospital was due to the treatment by Dr. P.

On the trial, the testimony of the plaintiff was substantially as set forth above. The doctor contended that there was no mistake in identity at all, but that the treatment was usual and proper and skillfully performed. Experts called on behalf of the defendant stated that the treatment given by Dr. P. was usual and customary in the course of such an examination as he had been requested to make. There was expert testimony on behalf of the plaintiff that the contrary was true. A verdict was rendered for the plaintiff amounting to $5,000. An appeal was taken and the court affirmed the judgment. The appellate court in its opinion said:

"It is doubtless true that if Dr. P. would have washed respondent's antrum as he did had he recognized respondent as S, the mere fact that Dr. P. mistook respondent for another of his patients would not of itself afford a basis for liability on the part of appellant; but as we read the evidence the same presents a conflict, not only as to whether or not Dr. P. mistook the identity of his patient, but also upon the question of whether or not the doctor would have performed such an operation upon respondent had he recognized respondent as S, and not mistaken him for G."

The court ruled that the issues were entirely issues of fact and that the jury had believed the story of the plaintiff and his experts, and would not therefore disturb the verdict.

FAILURE TO BE PRESENT AT DELIVERY

A woman who had been a patient of the defendant doctor for some years and upon whom he had previously operated, consulted him for examination and he ascertained that she was about three months pregnant. He arranged to have her call regularly from time to time and it was understood that he was to deliver her at the proper time. When he saw her last she was having a normal progress in pregnancy and the time of childbirth apparently was about four weeks off. At that time he warned her that as soon as she began to feel pains she should send for him. No word was heard from her by the doctor and one night at about eleven o'clock the doctor's wife received a telephone call to the effect that the patient had been having pains all day and delivery seemed imminent. The doctor had shortly before that been called out on an emergency consultation, and though his wife made every effort to communicate with him, she was unable to inform him of the patient's condition until about 2 o'clock in the morning when he returned home. At about 11:30 the doctor's wife had advised over the phone that the nearest possible doctor be called in to attend the patient and to deliver her, but there had been no subsequent communication. Therefore, the doctor upon reaching his home at a late hour, assumed that the patient had called in some other doctor and did not go to attend her. It seems that the woman delivered herself of a child some time before midnight and that the child died a few minutes after birth. No doctor was present until about 12:45 when an ambulance surgeon arrived, having been called by a friend of the patient. He observed that this had been a case of breech presentation.

Some time later on action was started by the woman in which it was claimed that the defendant was negligent in violating his duties to the plaintiff by failing to be present to care for the plaintiff at the time of her delivery, and that as a result her baby died at birth through asphyxiation, that she had been injured in the region of her pelvis and stomach, and had suffered severe shock and great pain.

The case came on regularly for trial before a judge and jury and after all the evidence had been put in on both sides, a motion was made by the defendant's attorney to dismiss the complaint on the ground that the plaintiff had failed to make out a cause of action. Said motion was granted.

NEWS NOTES

OYSTERMEN'S CONVENTION

The joint convention of the National Shellfisheries Association and the Oyster Growers and Dealers Association of North America, Inc., was held on August 18-20, 1931, in Sayville, Long Island, with over 200 representatives present, including scientists from Canada and England. The convention was remarkable for the high scientific character of the papers and discussions. A report of a similar meeting last year is contained in this Journal of September 1, 1930, page 1052.

The membership of the National Shellfisheries Association consists principally of scientists engaged in research on shellfish. It was these administrators and scientists both those from official bodies and those whose work is supported by the growers who contributed the leading papers; but the commercial dealers and producers not only listened intently to the papers, but also contributed to the discussion of the practical application of the scientific principles. In no other industry, except possibly that of dairying, would producers and dealers spend hours in listening to scientific papers whose basis but few of them fully understood, but whose conclusions are of great practical value to the dealers commercially, and from the health standard, to the people who buy the oysters.

Physicians generally will be especially interested in the medical phase of the program. A paper on the "Nutritive Value of Oysters" was given by Dr. R. E. Remington of the Food Research Commission of South Carolina. Much work has also been done in New York by Drs. Whipple and Wolf the past few years on the value of oysters in the treatment of the anemias, and their value has been shown to be equal to that of liver. One of the demonstrations shown at the convention was that of white rats used in feed experiments by Dr. O. M. Wolf.

An illustrated lecture by Dr. C. M. Yonge, of the Marine Biological Association Laboratory, of Plymouth, England, shed light on the reason for the special value of the oyster in anemia. The oyster has an elaborate system for taking food into its stomach where carbohydrate digestion takes place by means of enzymes, and of proteins and fats by large wandering phagocytic cells which are like the leucocytes of the human body. Absorption of food takes place in a series of microscopic tubes which extend out from the stomach and form the dark-colored organ which is popularly called the liver. The cells of this organ take up the smaller food particles and digest them in their own bodies, thereby performing a great part of the work of digestion. The "liver" of the oyster is therefore a glandular organ whose functions are similar to those of the glands of the human intestine and some of those of the liver.

Medical men know the association of copper with iron in the prevention and treatment of nutritional anemia. The oyster, too, has an intimate relation with copper and also manganese, and contains these metals in appreciable quantities and in a form which may readily be assimilated by the human body. Research workers have demonstrated that the value of oysters in anemia is equal to that of liver.

Another distinguished visitor was Dr. R. W. Dodgson, of the Ministry of Agriculture and Fisheries of England. He has developed a sound and scientific system for conditioning of the mussel which in his country is the "poor man's oyster." This conditioning process is conducted by him for the Ministry and has restored to food consumption enormous quantities of valuable seafood.

Still another visitor was Dr. John Eyre, Bacteriologist of Guy's Hospital, and scientist in charge of the biological survey and control of the Worshipful Company of Fishmongers. This organization is one of the few surviving English guilds dating from the 13th century. It has endowed and continues the support of several large charities in England, including boys' schools, and homes and hospitals for aged seamen and their wives. It is now largely a charitable institution but still has protective control over the fish and shellfish supply of London and maintains the highest type of standards for these foods.

The American shellfish industry, especially that of oyster growing and marketing, has been placed on a high plane within the last decade, until now its sanitary and scientific aspects are equal to those of milk production and sale. Research workers have delved into the secrets of spawning and growth of oysters and other shellfish; their food and its digestion; and the manner of their natural purification. All this knowledge has been applied eagerly by the growers and dealers, until now the industry is conducted on a thoroughly scientific basis by all the larger growers. The purity and sanitary qualities of the shellfish products are maintained by governmental inspectors in the same manner that milk is continuously inspected. One may purchase oysters anywhere in the

United States with the assurance that their sanitary quality is equal to that of milk.

The oyster growers are thoroughly alive to the value of the education of the public regarding the desirability of eating oysters, and they are planning to inform the public just as the dairymen are doing. The dairymen have had the advantage of propaganda of milk drinking put forth by boards of health, lay health organizations, and health periodicals until everybody appreciates the value of milk products. The oystermen may legitimately adopt the same methods of education, and, in fact, are planning to do so on a large scale.

One of the features of the Sayville Convention was a visit to the oyster houses of Long Island. The oystermen are fully aware of the value of sanitary surroundings, and they equip their new buildings with enameled handling tables and washers, and paint the walls a spotless white. The oysters, before being opened, are subjected to a conditioning process in pure water, and the finished product is packed in sanitary containers after the manner of milk. Among the latest methods is that of the quick freezing of the opened oysters, after the method successfully applied to fish and fruit. When this method comes into general use, oysters will be available the year around.

SUFFOLK COUNTY

A meeting of the Comitia Minora and members of committees of the Suffolk County Medical Society was held at Roe's Hotel, Patchogue, N. Y., on August 18, 1931, with eight members present.

Dr. Arthur T. Davis, Health Commissioner of Suffolk County, reported on the poliomyelitis epidemic, stating that thirty cases had been reported in the County since July 1st, seven of them being non-residents. Two had died and twelve recovered, leaving seventeen still under quarantine. The Commissioner had found a high degree of cooperation in both the doctors and the people of the County. The doctors were reporting the cases early, and were doing spinal punctures and taking blood serum from recovered cases for treatment of the present patients.

Dr. D. E. Overton of Hempstead reported on conditions in Nassau County, saying that fifty-eight cases had been reported up to date, and that he had been authorized by the County Society and the District State Health Officer to do diagnostic work and collect blood serum for treatment. He also reported on a meeting of the County Society held on August 4th, which had been attended by 125 physicians and was addressed by Dr. Lloyd Aycock. As a result of this meeting the doctors had entered into the work of prevention and control of the epidemic with renewed interest. (See this *Journal*, August 15, page 1048.)

Dr. Frank Overton, Chairman of the Public Health Committee, gave a report, including the following recommendations:

1. Support the County Health Officer, Dr. A. T. Davis:
   (a) Approve his past actions;
   (b) Support his requests and recommendations in the future.
2. Secure the cooperation of the family physicians by
   (a) Personal contacts of the County Health Officer and his deputies and assistants;
   (b) A letter from the Comitia Minora to be sent to every doctor.
3. Inform the people. A letter to be sent to every newspaper in the County.

On motion these recommendations were approved.

Dr. Overton submitted the following form for the letter to be sent to every doctor in Suffolk County, and on motion it was approved:

August 19th, 1931.

Dear Doctor:

The Comitia Minora and members of Committees of the Suffolk County Medical Society met at noon on Tuesday, August 18, 1931, and considered the measures which physicians should take for the prevention and control of poliomyelitis.

Dr. Arthur T. Davis, County Health Officer, reported conditions as follows:

Number of cases reported in Suffolk County since July 1:

7 non-resident
23 resident

Patients recovered, 12
Number still under quarantine, 17
Number died, 2; 1 a non-resident

Doctor Davis said that physicians were cooperating in an excellent way, and that they had diagnosed over half of the cases in the pre-paralytic stage. Serum had been given to all requiring it.

Doctor Davis also called attention to the letters and literature sent out by the Special Committee of the Medical Society of the State of New York, the more important being printed in the NEW YORK STATE JOURNAL OF MEDICINE of August 15, pages 1038 and 1048. This committee suggested that county medical societies adopt the following measures:

1. Educate and encourage physicians to make a diagnosis in the pre-paralytic stage of the

disease. This means that when the family doctor sees a suspicious case, he does not delay and wait for positive developments, but shall take steps *at once* to determine the diagnosis.

2. Advise every doctor to memorize the essential points of diagnosis in the pre-paralytic stage. There are nine important points listed by the special sub-committee of the Medical Society of the State of New York and printed on page 1038 of the *Journal* of August 15, as follows:

1. Fever
2. Headache
3. Rigidity of the neck
4. Tremor
5. Apathy
6. Vomiting
7. Retention of urine
8. Constipation
9. Sweating

Not all of these symptoms and signs may be present, but yet the doctor should look for them one by one.

The Comitia Minora recommends that every doctor carry this list in his pocket for easy reference when he is called to a case.

The Comitia Minora commends the physicians of Suffolk County for the active cooperation in dealing with the epidemic of poliomyelitis, and believes that a continuation of their preparedness will be sufficient to prevent the spread of the disease.

WILLIAM J. TIFFANY,
President, Suffolk County Medical Society;
E. P. KOLB, *Secretary;*

The Comitia Minora approved the following letter to be sent to every newspaper in Suffolk County:

To the people of Suffolk County:

The officers and committeemen of the Suffolk County Medical Society held a meeting in Roe's Hotel on August 18, 1931, to consider the situation in regard to infantile paralysis. The unanimous opinion was expressed that the County Health Department is handling the situation wisely and effectively; and also that family physicians are keenly interested to recognize the disease early and to give treatment before the disease has developed to a crippling stage.

A positive determination of the presence or absence of the disease is made by means of a spinal puncture, and an examination of the fluid.

If the disease is present, the approved treatment is that of giving serum at once.

The serum used in the treatment of poliomyelitis consists of the fluid part of the blood drawn from a patient who has recovered from the disease. The State Department of Health appeals to former patients to donate some of their blood, for which the State will make payment. Governor Roosevelt set an example by donating a pint of his own blood, he having had poliomyelitis several years ago.

The work of recognizing cases, giving serum, and collecting blood for making the serum is under the direction of Dr. Arthur T. Davis, County Commissioner of Health, whose office is in the County Court House, Telephone, Riverhead 2110. Dr. Davis is in a position to advise any physician or other person in the county regarding poliomyelitis, and to provide all necessary means for recognizing and treating the disease.

The officers of the Suffolk County Medical Society emphasize two measures:

1. Keep children away from crowds, for the disease is caught by contact with a person who already has the disease, possibly in a mild form.
2. Call a doctor *very early* when a child develops a mild sickness, especially headache and vomiting.

Remember, you must call a doctor before he can help you. In 1916 people concealed their cases, fearing to summon a doctor lest he call the sickness poliomyelitis—and the result was the spread of the disease to an alarming extent.

In 1931, people are calling a doctor early and are heeding his advice, and the result is that few cases have developed.

FRANK OVERTON,
Chairman, Committee Public Health.

POPULAR PAMPHLET ON POLIOMYELITIS

The Department of Health of the City of New York has issued the following pamphlet on poliomyelitis for general distribution among the people.

INFANTILE PARALYSIS (POLIOMYELITIS)
WHAT EVERYONE SHOULD KNOW ABOUT THE DISEASE
No. 1

What is infantile paralysis?

It is an infectious (catching) disease.

How is it spread?

It is spread from patient to others by direct contact.

Patients carry the germs in their mouth and nose at least several days after the fever.

The germs are present in the discharges from the mouth and throat of those ill and may be present in the nose and mouth of members of the same family.

The germs may be carried in mouths of healthy persons. These are the reasons why all sick people and crowds should be avoided.

Parents are advised not to visit children's camps and children's institutions so as to protect the children against infection.

What should be done to avoid infantile paralysis?

Follow the well-known and accepted rules that always protect one during outbreaks of infectious (catching) disease.

Avoid crowds and groups, whether public or private.

Avoid all sick children as well as older persons who are ill.

Mothers should see to it that children:

Wash their hands frequently during the day and always before eating.

Don't let your children be kissed by any one.

Are bathed daily.

Avoid the common towel and drinking cup.

Keep fingers and other objects away from nose, mouth and eyes.

Have sufficient sleep.

Have regular daily bowel movements.

Have fresh air and sunlight.

Have rest periods during the day so as not to become overtired.

In the care of the home, mothers should:

Dust with a damp cloth.

Kill all flies and insects.

Guard all food from flies and insects by means of covers, netting and ice boxes.

What ages are attacked?

Infantile paralysis is a disease of childhood. Any age may catch the disease. Most grownups escape.

What are the early symptoms?

Drowsiness, fever, headache, irritability, especially when moved, vomiting, usually stiffness of the neck, followed usually a few days later by inability to move some set of muscles or hands or legs or feet.

What food should be given to children?

Clean, wholesome food, suitable for this time of the year.

Plenty of milk, fruit, fresh vegetables and eggs.

Keep food, especially milk, in the refrigerator.

Avoid fried foods or foods liable to upset the stomach.

Do not give money to your children to buy drink or food. Buy them for your children.

Raw fruit and other foods eaten uncooked should be carefully washed.

What to do when a child is ill.

Send for a doctor at once. Do not try to diagnose the condition or take your neighbor's advice.

Put the baby to bed. Sponge the baby if the temperature is high. Stop feeding, give plenty of cool water.

Keep other children away from the sick child until the doctor tells you what to do.

If you cannot get a physician, notify the Department of Health.

TOMPKINS COUNTY

There being considerable poliomyelitis reported in New York and contiguous States the officers of the Tompkins County Medical Society, feeling it more than probable that cases of this dread disease would develop in this county, called a special meeting of this Society for the purpose of receiving instruction in the latest methods of early diagnosis and treatment.

This meeting was held August 13th, 1931, in the parlors of the Ithaca Chamber of Commerce at 8:30 P. M.

Dr. Wardner D. Ayer of Syracuse, a specialist in this disease, addressed the meeting.

The Doctor stressed the great importance of recognizing the early symptoms before paralysis developed, viz., fever, vomiting, headache, nearly always referred to the back of the head and neck, and more or less stiffness of the back of the neck.

When these symptoms are present spinal puncture should immediately be done, some of the spinal fluid be withdrawn and sent to the laboratory; and human blood serum from a previous case be injected in the spinal cord, which would oftentimes abort the disease before paralysis occurs, or at least very much lessen the extension of it.

He showed many slides of records of cases so treated with material benefit. He stated that paralysis usually begins about three days following the first symptoms.

J. H. Conway of Hornell, State District Health Officer, opened the discussion and complimented Dr. Ayer upon his presentation of the subject, and was followed by many of the members and visitors present. There was a large attendance of members, and visitors were present from several other County Societies.

Dr. Ayer was given an enthusiastic vote of thanks and the meeting adjourned.

WILBER G. FISH, *Secretary.*

THE DAILY PRESS

THE PERFECT GUEST

The irritating guest is the contributing cause of the nervous breakdown of many a housewife, especially during the hot week-ends of summer. The New York *Times* of July 29 contains the following editorial on the perfect guest:

"The first requirement is to arrive at a clearly stated time. The guest who says he will come after luncheon and then turns up before, may embarrass his hostess, even though she has told him that 'any time will be all right.' The housewife will also appreciate it if he will 'announce clearly and firmly after breakfast what meals he proposes to consume during the day.' An occasional absence at mealtime is nothing to be apologized for; it only endears the guest to his entertainers.

"No guest should ever admit eccentricities of diet. 'If you are a dyspeptic or a vegetarian, either do not be a guest, or else consume recklessly everything which your doctor has told you is poison to your system.'

"Don't wait for your hostess to say: 'Well, you have had a busy day, and I must not keep you up any longer.' Make the fatal remark yourself. To come in at 2 A. M. without making a sound displays skilled guestcraft. To turn off all the lights within reach means more merit acquired."

TESTS FOR DRUNKENNESS

The Police Department of New York City introduced a new system in dealing with chauffeurs accused of being intoxicated while driving automobiles. The New York *Herald Tribune* for August 13th described the record blank which every police officer is required to fill out when he brings an arrested driver to a station house. The former custom was described as follows:

"Heretofore in New York whenever a motorist, male or female, has been escorted from a driver's seat to one of those houses where the lights are always green, and the patrolman has told the sergeant or lieutenant that his prisoner was tipsy, the desk officer has telephoned to a hospital and asked for an ambulance surgeon. It was up to the ambulance surgeon to say whether the prisoner was intoxicated or sober. If the doctor said "drunk," then in all likelihood he would have to go to court when the case was called.

"Now doctors are human, and if they can get out of going to court they like to do it. One way to avoid it, in these intoxicated driver cases, is to pronounce the motorist sober, and forget him. Which, it appears, is just what a great many doctors have done despite the firm belief and conviction of the patrolman on the beat that his captive was plastered, boiled or even blotto."

The new plan is described as follows:

"The examinations will be made immediately a motorist walks, staggers or is carried into the station house. A full report will go to the magistrate when the case is called, which is usually several days after the arrest—time enough to give even the tightest of prisoners ample opportunity to sober up.

"The new examinations were prepared by Deputy Chief Inspector John J. Hennessy after long research and profound study of thousands of treatises and documents concerning the application of the oldest of the laws of relativity—those by which a man is judged to be intoxicated or not intoxicated.

"Meanwhile the ambulance surgeons will rest unbothered in the hospital or go clanging through the streets on more serious missions than that of determining whether a man in a police station is intoxicated or sober. When the case comes to court the magistrate will have a report of facts and impressions recorded immediately after the arrest. Inspector Hennessy hopes it will prove an improvement over the old system."

The new form is shown on the next page.

There are two practical reasons for the use of the blank.

1. To prevent a change of opinion on part of the officer, mainly from the influence of friends of the accused.

2. To call attention to a considerable number of details of observations of importance in the determination of drunkenness or sobriety.

It is not generally known among physicians, and even lawyers, that the opinion of a lay observer regarding the drunkenness or sobriety of an accused person must be admitted when offered as evidence. This lay point is discussed clearly and fully in a legal editorial by Mr. Lloyd P. Stryker printed in this JOURNAL on December 1, 1927, page 1321.

Mr. Stryker alludes to the need that chemical tests for the presence of alcohol in the body be

combined with mental tests. Such a combination test was described in this JOURNAL of August 15, 1927, page 932. New York City has not yet introduced this test, but doubtless that step will be taken soon.

The New York *Times* of August 15 describes the proceedings in a station house at the examination of the first person arrested for driving an automobile while drunk. The *Times* gave the details of the prisoner's responses to the several items on the questionnaire and ended with the conclusion of the desk sergeant, "Not intoxicated," but the *Times* continues:

"Nevertheless he (the prisoner) was locked up on charges of driving while intoxicated and assault in the third degree. He will have a hearing this morning. It was pointed out that the new test is designed to enable the arresting officer to testify, in detail to the prisoner's condition, since in the past he has often been able to give only his general impression, which the courts have held is not enough."

BOOK REVIEWS

THE VITAMINS. By H. C. SHERMAN and S. L. SMITH. Second edition. Octavo of 575 pages. New York, The Chemical Catalog Company, Inc., 1931. Cloth, $6.00. (American Chemical Society Monograph Series, No. 6.)

The Vitamins is an American Chemical Society Monograph, and the authors have made an attempt to "summarize the very considerable amount of information which has been gained regarding the chemical natures of the individual vitamins, and the more voluminous knowledge regarding their roles in life processes, their formation and distribution in nature, their relative abundance in different types of food materials and stability under the conditions to which these are likely to be subjected." One can gain an idea of the tremendous amount of material which has been considered, from the fact that nearly two hundred pages of the book are given over to bibliography, and the story of the vitamins is told from the beginning, when the first lessons were learned from scurvy, to the latest experimental work. In all, six vitamins are discussed, and a chapter is given to each. It is obviously an authoritative treatment of the subject, and yet the authors taking into consideration that many and varying types of individuals would be interested in the matter, have prepared not a pure chemical treatise, but an interesting and readable account of the facts, which in this second edition they have brought up-to-date.

L. C. JOHNSON.

THE TREATMENT OF BEHAVIOR DISORDERS FOLLOWING ENCEPHALITIS. An experiment in re-education. By EARL D. BOND, M.D., and KENNETH E. APPEL, M.D. Octavo of 163 pages, illustrated. New York, The Commonwealth Fund Division of Publications, 1931. Cloth, $1.75.

An interesting frank account of a well conducted effort, termed an experiment, to see how much can be accomplished by application of psychiatric methods, in correcting such infirmities in this youthful class of cases. In the main no gross force, corporal punishment, medication, or prison discipline, but system, grouping, surroundings, occupation, personal influence, regular hours, and study of the individual child. In the six-year period there were at various times 62 children of 12 years or under, 48 being post-encephalitic, and 14 comparable cases as control. Besides discussion of principles and patients the facts and results are shown by tables, charts and a summary of cases. Practical cures in some, improvement in many and several failures, a most encouraging degree of success. The attempts to find deep significance in bits of child dreams and such marks sounds more like a guessing game than is probably intended. It is admirably printed, and a source book for all interested in this field.

WM. BROWNING.

RECENT ADVANCES IN CARDIOLOGY. By C. F. TERENCE EAST, M.A., M.D., and C. W. CURTIS BAIN, M.C., M.B. Second edition. Octavo of 353 pages, illustrated Philadelphia, P. Blakiston's Son & Co., Inc., 1931. Cloth, $3.50. (*The Recent Advances Series.*)

This comparatively small book covers the whole field of cardiology. It provides an admirable supplement to the ordinary text book in cardiology. It contains a great deal of valuable information and discusses all the major changes which have taken place in this subject in recent years. The book is well written and there is an interesting discussion of points which are still in dispute. Although some of the material is somewhat advanced it is presented in a comparatively simple way so that it ought to be readily understandable by those who have not had an opportunity of studying the subject closely. Each chapter is followed by a small list of references to the leading papers on the subject dealt with. Anyone interested in internal medicine as well as cardiologists will find the time well spent in reading this admirable book.

J. HAMILTON CRAWFORD.

THE CRIMINAL, THE JUDGE, AND THE PUBLIC. A Psychological Analysis. By FRANZ ALEXANDER, M.D., and HUGO STAUB. Translated from the German by Gregory Zilboorg, M.D. 12mo of 238 pages. New York, The Macmillan Company, 1931. Cloth, $2.50.

To thoroughly appreciate this book, one must have a reading knowledge of psychoanalysis. And the reader must understand the significance of the divisions of the instinctive (unconscious) psychic life,—into the id (the deepest layer); the ego, and the super-ego. (From the latter is developed the ego-ideal which is based on the ethical principles taught by parents, teachers, religious leaders, society, etc.) The conscious part of the super-ego we know as conscience.

Alexander says that both neurotic symptoms and antisocial conduct, are motivated in part by the instinctive life. He shows the part the ego and the super-ego play in both types of reactions.

The criminal super-ego makes little attempt to restrict the instinctive drives of the id, in favor of society. Of course crime is the result of many psychic motives. In many instances criminality results from a faulty bringing up, Alexander says.

The neurotic expresses his trends by symptoms (symbols); the criminal, by antisocial acts.

The super-ego is the inner representative of reality and depends for its strength on the relation between the ego and authority.

Alexander divides criminals into three classes:

1. Neurotic criminals.
2. Normal criminals.
3. Organically determined criminals (imbeciles, schizophrenics, etc.)

According to Alexander, the chief role of the expert of the future is to say how much the ego, and how much the unconscious played in the given antisocial act. He says of course that there will be no official recognition of the unconscious in our courts in the near future. He feels that perverts need hospital care rather than prison sentences.

Alexander's discussion of the unconscious feeling of guilt, the need of punishment, and the questions of atonement and expiation are most masterful. According to him expiation, retaliation, and compensation all gratify the socially inhibited sadism which interferes with a rational treatment of the criminal problem.

The period when a fine social super-ego is chiefly developed (6-12 years) is the time to really begin to prevent crime. For a fine ego-ideal is the best crime preventative.

All students who are interested, not only in criminality but in the neuroses, should possess this book which is an analytic study in advance of the times, written by one of the master-minds of psychoanalysis.

JOHN F. W. MEAGHER.

WHITE HOUSE CONFERENCE, 1930 ADDRESSES AND ABSTRACTS OF COMMITTEE REPORTS. White House Conference on Child Health and Protection called by President Hoover. Octavo of 365 pages. New York, The Century Company, 1931. Boards 50c.

This book contains the report of the various committees and their recommendations read before the national Child Health Conference, at Washington in November, 1930.

The subject matter of the papers read and discussed are varied and interesting. The entire field of Preventive Pediatrics from prenatal care to child labor are discussed in detail.

The article by Dr. Louise Stanley, on "The Family and Parent Education" deserves special mention. This should be read by every interested man and woman.

Our statesmen and legislators will find this book a valuable guide for their daily tasks. The book will interest every doctor as a citizen but not as a practicing physician.

It certainly makes good reading for the well informed individual for only in such special texts can justice be done to such a voluminous report. The socially minded citizen will find in this book a fund of information which could only be briefly recorded in the daily press. This publication makes it available in its entirety. One can look forward with interest to the next copy reporting the more recent conference held in Washington the early part of the current year.

HARRY APFEL.

PRACTICAL CLINICAL PSYCHIATRY, for Students and Practitioners. By EDWARD A. STRECKER, A.M., M.D., and FRANKLIN G. EBAUGH, A.B., M.D. Third edition. Octavo of 553 pages, illustrated. Philadelphia, P. Blakiston's Son & Co., Inc., 1931. Cloth, $4.00.

For one who wishes to study psychiatry by the case method, this book by Strecker and Ebaugh is to be highly recommended. Their line of approach is more along the lines of orthodox psychiatry. They have only utilized the material of the analytic literature to a slight degree. Both of the authors are well-known in the American mental hygiene movement, and what they have to say is not only scientifically acceptable, but what is almost as important, their style is such as to make their book very interesting to read.

JOHN F. W. MEAGHER.

HEART DISEASE. By PAUL DUDLEY WHITE, M.D. Octavo of 931 pages, illustrated. New York, The Macmillan Company, 1931. Cloth, $12.00. (Macmillan Medical Monographs.)

This volume is fundamental, clear, concise, comprehensive, accurate, modern, carefully written, logical, well-presented, readable, understandable, and instructive. The subject is presented in four parts: cardiovascular examination, symptoms and signs; the incidence, causes and types of heart disease; structural cardiovascular abnormalities; and disorders of cardiac function. The book is one which must be studied carefully; it is of the type which but little can be absorbed daily, as practically all information and useful knowledge of this interesting but difficult subject is presented not only as a text book literature. The is exemplified he writings upon the to is unusual and it study.

A complete bibliography of one hundred and ninety pages is added. An appendix of one hundred and eight unsolved cardiovascular problems gives the reader an idea of some of the important questions upon which to expend our efforts, and indicates some future work upon this subject. No review can present adequately the value of this study.

The publishers have given us a volume of which they may be proud, excellent paper, clear readable type, with illustrations of the finest workmanship. Everyone who attends the sick should have this volume for study and ready reference.

HARRY MONROE MOSES.

AIDS TO BACTERIOLOGY. By WILLIAM PARTRIDGE, F.I.C. *Fifth* edition. 16mo of 311 pages. New York, William Wood & Company, 1931. Cloth, $1.75. (Students' Aids Series.)

This little booklet presents the essentials of bacteriology. There is adequate description of the usual bacteria found in disease and also of those that are less common. The apparatus required for the study and identification of bacteria, the preparation of nutrient media, and routine examination of bacteria are described in separate chapters. The bacteriology of the more recently discovered diseases is also given. There are also chapters on the bacteriological examination of water, air, soil, and food. The book should be of great help to the student of bacteriology.

EDWARD H. NIDISH.

CRIPPLED CHILDREN: Their Treatment and Orthopedic Nursing. By EARL D. MCBRIDE, B.S., M.D. Octavo of 280 pages, illustrated. St. Louis, The C. V. Mosby Company, 1931. Cloth, $3.50.

This is a 275 page book with 159 illustrations, dealing with the elementary features of orthopedic conditions. It is very precise in the discussion of the various nursing problems incidental to each disease. For those who have to give courses in Orthopedic Nursing it will be found invaluable. It is highly recommended to Instructresses in Nurses' Training Schools. It should be in the library of every Nurses' Home.

Like other volumes of its kind, it contains much valuable information for the General Practitioner and the Pediatrician. It makes a nice little manual for the Orthopedic Surgeon, particularly the younger man, who is often confronted with the problem of advising precise nursing care after the desired immediate result from his operative or non-operative treatment of an orthopedic problem has been attained.

D. E. M.

A SYNOPSIS OF THE UNITED STATES PHARMACOPŒIA AND NATIONAL FORMULARY PREPARATIONS. By H. J. FULLER, PH.C., PHM.B. Octavo of 247 pages. Philadelphia, P. Blakiston's Son & Co., Inc., 1931. Cloth, $2.00.

Professor Fuller's Synopsis enables the pharmacist or physician to observe the voluminous official volumes from the vantage point of a birds-eye view. Primarily to supplement the student's survey of the larger volumes, the Synopsis will be of unusual service to any pharmaceutically minded person, for whom it will assume the rôle of an elaborate index. It is not intended as a substitute for the Pharmacopœia and the Formulary but to strip them down to their skeleton.

Professor Fuller's tabulations of the Official Preparations classify them according to their form: aceta, acida, alkaloids, ampullae, and so on. Each reference table regarding synonyms, com- sage. His book is gener- ons. A section is reserved nt details of posology in a form conducive to ready reference.

The Synopsis will undoubtedly come to be considered an indispensable part of the reference equipment of technical office and library.

FREDERIC DAMRAU.

OUR NEIGHBORS

ACTIVITIES OF MILWAUKEE COUNTY MEDICAL SOCIETY

The July number of *Minnesota Medicine* contains an address given by Mr. Theodore Wiprud, Executive Secretary of the Milwaukee County Medical Society, on "Experiences in County Medical Organization," on February 7, 1931, before the Annual Conference of Secretaries of County Societies of Minnesota. The address consisted principally of a description of the activities of the Milwaukee County Society. Doctor Wiprud, in describing the works of the Society during the two years in which he has been Secretary, said:

"To meet the demands which are made upon it the county medical society must be organized. This does not mean the loosely organized unit which has become so familiar, where infrequent scientific meetings comprise the sole activity. It means a unit that will not only improve its members scientifically, but will also assume its responsibility in other directions, not least of all to the community. To do this effectively a full-time secretary or a member who can give a large portion of his time to Society activities is needed. In large centers a part-time secretary has a thankless and difficult job. He cannot possibly do justice to the job entrusted to him and still give adequate attention to his practice."

"A rather unusual situation existed in Milwaukee prior to the inauguration of the new program with a full-time secretary. Difficulties between the Health Department and the medical profession had multiplied with consequent ill feeling. Newspapers were none too friendly, and seldom favored the medical profession's view of any subject under discussion. This in itself was not unusual, but the fact that other organizations were the source of medical information, and that a privately owned physicians' telephone exchange served over 200 physicians, was unusual. Officers of the Society had been disturbed by the possibilities of this telephone exchange under private management. While it was then being ethically operated, under different management it might be a source of great danger to the prestige of the medical profession of Milwaukee."

Physicians' Service Bureau: The first major activity undertaken by the new secretary was the purchase of the physicians' telephone exchange and its organization under the name of "Physicians' Service Bureau." The report says:

"The Bureau has proved exceptionally valuable to our members. To use the service a member must subscribe to the Bureau and pay a monthly fee, for which he is rendered twenty-four-hour telephone service. The Bureau acts as a connecting link between the patient and the physician. We opened on November 1, 1929, with 220 members. At present we have 270. The equipment and personnel of the Bureau has been improved from time to time until at present we believe we have a very efficient service.

"The Physicians' Service Bureau acts as an information bureau for the public. Calls are constantly received on every conceivable subject. Over 52,000 incoming and outgoing calls were handled last year. A third of these were inquiries. Most of them were for specialists. The procedure followed is to refer these inquirers back to their family physician. If they have no family physician, a classified list of specialists, approved by our Educational Committee, is referred to. Three names are given from which the inquirer makes his choice. When the next call is received in the same specialty, the next three names are given. In other words, the list is rotated. No information in regard to treatment is ever given by an operator."

Scientific Programs: Scientific meetings were described as follows:

"Of course our scientific programs are an important feature. Attendance has so greatly increased that our officers have been much elated. An average attendance previous to last year was 100. This was increased to an average of 188. At four out of eight of our monthly meetings, the attendance ran over 250.

"This increase was partly due to the fine programs, the publicity given the meetings in our monthly publication, and the last-minute notices sent members. An added attraction was the social hour which followed each scientific meeting. This hour was given over to visiting and getting better acquainted. Buffet lunch was served during the social hour, and physicians, being human, enjoyed this a great deal. We feel that this feature has helped to stimulate better feeling and understanding among our members."

Education: Educational work among physicians is described:

"A number of unusual activities were sponsored by the Educational Committee. Among them were courses in public speaking and medical writing. The public speaking course, which was given by Professor Ewbank of the Public Speaking Department of the University of Wisconsin under the joint auspices of the University and the Medical Society, was a decided success. Over

70 members enrolled. The course in medical writing has attracted wide and favorable comment. There are 45 members enrolled in this course, which is also sponsored by the Society and the University."

Surveys: A survey was made of charity work done by doctors:

"A survey has been in progress during the past year under supervision of the Social Medicine and Medical Economics Committee. The first survey completed was that of charity work being done by members of the Society in Milwaukee County. . . . This report revealed that our physicians were doing charity work valued at a million and a half annually, over most of which they had no control. Our survey is continuing in all fields of medical practice, and just now we are particularly interested in our county institutions. We feel that much will be accomplished by this committee."

Collections: A collection service was discussed:

"A collection service operated under the supervision of the Society but not by it, has been planned, and we expect that it will be opened on or about March first. Some societies have had unfortunate experiences with such a service. However, others have done well, particularly when carried on as an enterprise separate from the Society."

Publication: A monthly publication is described as follows:

"Our monthly publication, *The Milwaukee Medical Times,* we believe has stimulated the interest of our membership. It has been developed from a four-page folder to a forty-page journal. Many favorable comments in regard to its contents and appearance have been encouraging to the editors. The *Times* has been self-sustaining."

Speakers' Bureau: Public health education is conducted as follows:

"The Speakers' Bureau provides speakers for lay organizations. Since its organization a little over six months ago, increasing demands have been made upon it. Daily we receive calls for speakers. People are interested in medical and health subjects, and many favorable comments are made upon our speakers by the organizations before which they appear. Lists of subjects are sent out to clubs, parent-teacher organizations, and other groups. They select the subject about which they wish to hear, and learn the name of the physician who will speak on it afterward. This Bureau will become increasingly useful.

"All press information is given out through the Executive Secretary's office. Every effort has been made to give the newspapers legitimate and

Modern diets often lack minerals

To-day, authorities are stressing the importance of the essential mineral salts. In addition to building sturdy bones, and blood rich in hemoglobin, these mineral elements aid metabolism and contribute to nervous stability.

Yet many modern diets cannot be depended upon to furnish the proper quota of minerals, and therefore millions of people suffer from the effects of demineralization. Cooking destroys a variable amount of the mineral value of foods — in some instances as high as 76 per cent.

To correct this loss and to remedy demineralization — with its attendant symptoms of nerve fag, neurasthenia, lowered vitality and loss of energy—a tonic rich in mineral salts is needed.

Fellows' Syrup contains the mineral salts of sodium, calcium, potassium, manganese, iron and phosphorus, together with the added metabolic stimulants — strychnine and quinine. Sixty years of clinical experience the world over testify to its value as a tonic.

Suggested dosage: A teaspoonful in half a glassful of water three or four times daily.

reliable information, and they have responded splendidly."

Health Department: Dr. Wiprud referred briefly to the strained relations of the physicians with the City Health Department, and the cooperation brought about simply by a personal contact with the Commissioner in a friendly manner. The first cooperative action was that of immunization against diphtheria.

Health Council: A new body, the Health Council, is described as follows:

"Our Health Council, composed entirely of our members, was created last year. The Council was created for the purpose of developing a public health program in which the Society would assume leadership. More recently it was enlarged to include representatives of hospitals, and nurses' organizations, who will meet with the Council quarterly to discuss mutual problems. The first session of the enlarged group was held the first week of this month.

"The Health Council is going to put forth a systematic effort to interest the rank and file of the profession in periodic physical examinations. First of all it will attempt to determine what comprises an adequate, minimum physical examination to be given by a general practitioner without laboratory and *x*-ray equipment available. Such an examination should be complete enough to reveal the necessity, if any, of extensive laboratory tests.

"To prepare our physicians better for this work, practical post-graduate courses in diagnosis will be given. The first, which is to be given in March, will be an intensive course on the diagnosis of the chest diseases."

Results: The results are summed up as follows:

"While there is much tangible evidence of progress, we feel that the intangible accomplishments have been of equal if not more importance. The prestige that the Society has gained in the past year because of its improved organization has placed us in a different and superior relation to all outside groups. Daily we are impressed with the value of this increased prestige. One evidence of it is shown by the constant seeking of advice and approval of the Society by organizations and individuals who never heretofore gave the Society consideration."

DISSENSION IN KNOX COUNTY, ILLINOIS

The July issue of the *Illinois Medical Journal* contains an account of the proceedings of the

(*Continued on page* 1115—*Adv. xix*)

(*Continued from page 1114—Adv. xviii*)

House of Delegates of the Illinois State Medical Society, in which both the Secretary of the State Society and the Councilor of the Fourth District make lengthy reports on the dissensions in the Knox County Medical Society Dr Coleman, Councilor, reported·

"There have been troubles between the members of the Knox County Medical Society for many years past, resulting in the formation of factions, and finally of personal animosities, so intense that they are hard for an outside individual to believe.

"The present trouble seems to date quite definitely to the standardization of the Galesburg Cottage Hospital, by the American College of Surgeons, in 1929. At this time, all physicians of Knox County in good standing were invited to become members of the staff, and as is the custom in such standardized hospitals, were also to sign a hospital pledge, which a majority refused to sign. They were permitted to practice in the hospital for several weeks, after which a time limit was set and they were notified that after that time, no one could take patients to the Cottage Hospital who had not signed the hospital pledge.

"The Knox County Society had a hospital committee which had fifteen or sixteen members and they held many meetings, held conferences with the hospital board and drew up an agreement which they tried to have the board adopt. The board objected to three clauses in this agreement and refused to adopt it, so the society by a majority vote declared the Galesburg Cottage Hospital an unethical institution dating from August 15, 1930.

"Sometime following this last meeting, when neither side had made any concessions, a petition was sent to the Council, bearing signatures of the majority group, and a request that the Knox County Medical Society be allowed to surrender its charter, and that a new charter be issued to the officers of the society, all of whom were members of the majority group. This was apparently a method to force the minority group out of organized medicine, and the minority sent in a protest.

"A compromise meeting was held but a little while later.

"Notice was received that the majority group had preferred charges against seventeen of the minority group, on from one to six counts. The counts varied from 'Unethical Conduct,' details not specified, and 'Supporting an unethical institution, the Galesburg Cottage Hospital,' to 'Rebellion against the Society,' which last was preferred against all seventeen.

"Next a hearing was held lasting two hours.

"Many statements were presented, some of them sworn to and were introduced as evidence.

(*Continued on page 1116—Adv. xx*)

Here

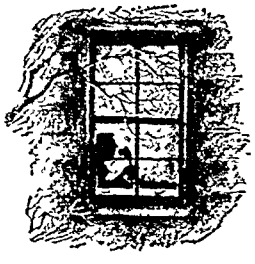
is one of the advertisements of The Sugar Institute

THE advertisement reproduced here is one of the series appearing in publications throughout the country. In order to keep the statements in accord with modern medical practice, they have been submitted to and approved by some of the leading authorities in the field of human nutrition in the United States. The Sugar Institute, 129 Front Street, New York.

(*Continued from page* 1115—*Adv. xix*)

Those by one group would be presented by good reliable men, and would seem to be of decidedly damaging character to the other group; but the second group would present evidence that seemed equally reliable, from equally good men, that would refute the damaging evidence, and in turn present more of the same type of evidence which would be equally damaging.

The result was that the censors cited fifteen members for 'Rebellion against the Society.' Then both factions petitioned the State Society to annul the charter of the Knox County Society, so that the doctors would be free to form a new one. The report closes:



" 'Numerous suggestions for solving their admittedly difficult problem have been offered. The most practical appear to be either re-issue a charter to a neutral group or to a few of the less vehement of both sides, and then have the remainder readmitted slowly enough to prevent a recurrence of the trouble; or to allow one group to join the adjacent societies and issue the charter to the remainder. Another possibility might be to allow all the physicians in the county to have equal access to both hospitals. This last method, possibly the best, is beyond the control of the Council. The adjoining counties so far, have refused to admit any of the Knox County men; and as to finding individuals who are not very zealous on one side or the other, in my opinion, there are none. In consequence the county is at present without a component society and neither faction has been able to work out a compromise.' "

POPULAR HEALTH PUBLICITY IN ILLINOIS

The authorization of the House of Delegates of the Medical Society of the State of New York that popular medical publicity be started, makes the report of similar work in Illinois interesting to New York physicians. The Educational Committee of the Illinois State Medical Society reporting to the House of Delegates on May 5, according to the *Illinois Medical Journal* for July, said:

"*Speakers' Bureau:* Five hundred and fifty-three health talks were given by members of the Illinois State Medical Society before a total audience of 180,000. These speaking appointments were about equally divided between Cook County and down-State.

(*Continued on page* 1117—*Adv. xxi*)

Do you like to be remembered?

EVERYBODY does—at the right time. But many a patient waits for the night to think of the doctor, because pain has a way of pressing into the limelight when silence has spread its blanket under the stars. And nobody likes the ring of the telephone bell at two a. m.

Peralga will often silence that sleep-disturbing telephone bell, by relieving pain, discomfort, nervousness, if you will remember to provide in the daytime for the eventualities of the night. Peralga is not narcotic—you can safely prescribe it for any painful condition, to be used when needed.

Shall we send you a trial amount?

Peralga is a combination of amidopyrine and barbital

PERALGA

for the relief of PAIN

SCHERING & GLATZ, Inc., 113 West 18th Street, New York City

(*Continued from page 1116—Adv. xx*)

"The Educational Committee has scheduled physicians to address Teachers' Institutes, high school assemblies, women's clubs, parent teacher associations, university clubs, household science groups and home bureau organizations, farmers' institutes, nurses' alumnæ associations, churches, business and professional clubs, fraternities at universities, young mothers' clubs, Y.M.C.A., Y.W.C.A., Chambers of Commerce men's service clubs as Rotary, Lions, Optimist, Kiwanis Special emphasis has been given to subjects of current interest

"Over 40,000 high school students of Illinois heard health talks given by members of the speakers' bureau.

"Radio" Four hundred and sixteen health educational talks were given over the radio by physicians All material was prepared by individual physicians and approved by the Committee Due to the fact that the studios of Stations WJJD and WGN are in Chicago, members of the Chicago Medical Society were asked to prepare and broadcast these as radio talks

"The Committee has been responsible for three ten-minute talks each week from WJJD and for a weekly ten minute talk from WGN The Young Mothers' Hour sponsored by the Chicago Pediatric Society and the Educational Committee has been given every morning for the past twelve months and will be continued indefinitely. The excellent material presented in these talks has received favorable comment from many sections of the United States.

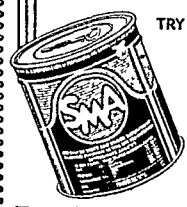
"Press Service. Eleven thousand eight hundred and ninety-eight articles announcing medical meetings, educational health articles and special features were released to Illinois newspapers Every paper in the State has received material from the office of the Committee

"During Health Promotion Week, special articles were released to all newspapers and this material covered the subjects designated for emphasis each day of the week

"Notices of the Summer Clinics sponsored by the Chicago Medical Society were released to all papers in the State and to all State Medical Journals.

"An article emphasizing the importance of discovery and correction of defects in pre-school children was written and released to all newspapers in communities registered for the Summer Round-Up campaign by the Parent-Teacher Associations.

"One hundred and twenty-four health education articles were written and approved by the Committee These articles were used in about



(*Continued on page 1118—Adv. xxii*)

No modification necessary . . .

It is not necessary to further modify S.M.A. for normal full term infants, for the same reason that it is not necessary to modify breast milk - for S.M.A. contains the essential food elements in proper balance. Because of this close resemblance to breast milk, the very young infant can tolerate the fat as well as the other essential constituents of S.M.A. and it is possible to give it in the same strength to normal infants from birth to twelve months of age.

As the infant grows older, therefore, it is only necessary to increase the total amount of S.M.A. diluted according to directions.

Orange juice, of course, should be given the infant fed on S.M.A. just as it is the present practice to give it to breast fed infants, to supply an adequate amount of the anti-scorbutic vitamin "C".

100 newspapers of the State as a daily or weekly Health Column over the signature of the local county medical society or the Illinois State Medical Society.

"*Miscellaneous Service:* One hundred and thirty moving picture films were secured for lay and medical groups. Most of the films came from the State Departments of Public Health, the U. S. Bureau of Mines at Pittsburgh, Metropolitan Life Insurance Company of New York, and the Y.M.C.A.

"Twenty-five Poster exhibits were sent to schools.

"One exhibit of educational material available at the American Medical Association was sent to the annual meeting of the Illinois Biology Teachers Association.

"Twenty-four packages of material on State Medicine were supplied to debating teams in colleges of Illinois, Michigan and Indiana. The Committee has asked these debating teams to furnish it with copies of the material presented in these inter-collegiate debates.

"Three hundred and sixty-five package libraries loaned to physicians and 25 special folders compiled on requested subjects."

There Is No Specific For

Loss of Appetite

—just when food is most needed to build up strength after disease has made its inroads.

But let us send you two bottles of Guiatonic, and give it a chance to live up to its name as a "tonic."

The hypophosphites of iron, quinine, strychnine, manganese, calcium and potassium combine with creosote and guaiacol to stimulate appetite, to furnish an abundance of minerals (including phosphorus) and thereby promote cell reconstruction.

IN addition, after febrile diseases, the creosote and guaiacol tend to prevent secondary intestinal infection and intestinal fermentation.

ANNUAL MEETING IN NEW JERSEY

The House of Delegates of the Medical Society of New Jersey was held in Asbury Park on June 3 and 4, 1931, with the President, Dr. George N. J. Sommer, in the Chair. The minutes are printed as a supplement of the August Journal of the Society.

The procedure of the House of Delegates of New Jersey is radically different from that in New York in three important particulars:

1. The president of the State Society presides, while in New York a speaker skilled as a parliamentarian occupies the Chair.

2. The officers read their reports to the House, while in New York the reports are published in the *Journal* a month in advance of the meeting, and a reprint is mailed to every delegate.

3. The New Jersey House has a single committee, that on Business, to which all reports and notices are referred; while in New York, fifteen reference committees of five members each, are appointed a month before the meetings, so that they may give due consideration to the reports and to proposed legislation. One-half of the elected delegates from county societies of New York serve on reference committees.

The first committee to report was that on Publication, which gave the following summary of the finances of the Journal:

"Amount of advertising secured by Cooperative Advertising Bureau of the A.M.A.	$4,854.42
"Amount of advertising secured locally	4,549.47
"Amount of discount and commission allowed Cooperative	1,176.80
"Amount of discount allowed local advertisers	48.88
"Amount of commission O.K.'s local canvassers	280.75
"Amount of commission paid local canvassers	264.41
"Total amount of advertising (net)	9,403.89
"Total cash receipts, all sources	9,114.87
"Total amount paid Treasurer	8,850.46"

The Budget Committee presented the following estimate of expenses for next year:

"Publication Committee	$15,000
"Welfare Committee	750
"Credentials Committee	400
"Executive Salaries	14,000
"Executive Office and Rent	3,650

(*Continued on page 1120—Adv. xxiv*)

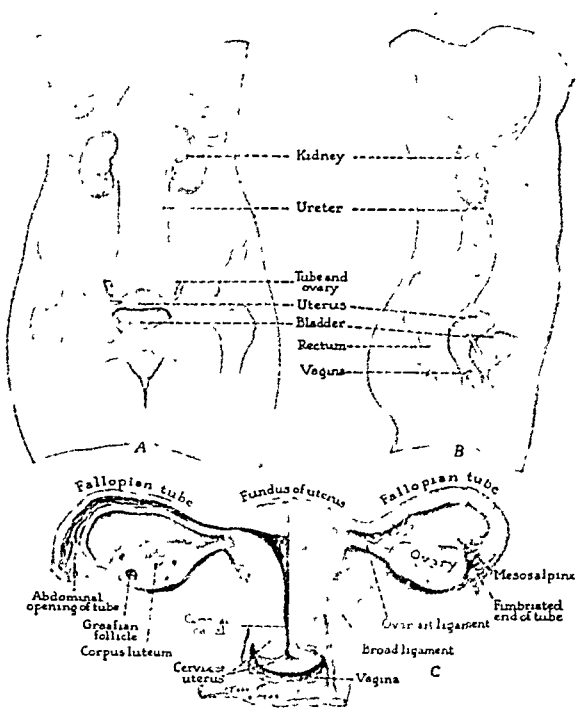
(*Continued from page* 1119—*Adv. xxiii*)

"Executive Travel Expense	2,000
"Treasurer	100
"Secretary's Salary	1,500
"Secretary's Expenses	2,200
"Legal Expenses	1,000
"Printing and Stationery	2,000
"A.M.A. Delegates (a reduction from last year)	100
"Tri-State Conference	150
"Conference of County Society Secretaries and Reporters	150
"Contingent and Miscellaneous	2,500

"The suggestion was brought up to the committee, however, that there might be a possibility of reducing the per capita assessment $1 if the House of Delegates so sees fit. However, your committee recommends the same assessment of $15. I think we all feel that we should have some reserve. If we take the figures, 2,706 members at $15, that gives us an anticipated revenue of $40,590. We probably shall get $850 for interest and the Publication Committee will probably return $8,500, which gives us an income of $50,000 approximately. Our expenses are $45,500. That does leave something over $4,000, but bear in mind that we have taken out that reserve of $3,000. I feel, and I think the committee feels, we should have that $4,000 as reserve and certainly $1 less on the assessment isn't going to make very much difference to the average doctor, probably 4 or 5 cigars."

There was considerable discussion as to which was the first day of the annual meeting of the State Society, for the Nominating Committee should be appointed on the second day. The decision was that the meeting of the House of Delegates constitutes the first day of the meeting of the State Society.

The House voted its disapproval of any member of the State Society taking out a patent on any medical article.



The reports of the Editor and the Secretary covered nine pages of the Supplement to the Journal, and were read to the House.

Regarding printed reports from county medical societies, the Executive Secretary, Dr. H. O. Reik, reported:

"There have been complaints that some counties regularly occupy more space than others on the Journal; an implication that favoritism has been shown in some quarters. If any county is not showing up satisfactorily, by comparison with others, the fault lies with the complaining organizations. From some counties we receive

excellent reports. From some counties we secure reports only by harrassing the reporter with repeated appeals. The published county society report is an accurate index of the character and ability of the reporter. As each society elects its own reporter, each possesses the power to control the amount of journal space required."

Dr. Reik also referred to an exhibit table, on which the official journals of all the States were shown.

The Executive Secretary also reported that District Branch meetings had been held in four of the five Councilor Districts of the State. This is the first year that the meetings have been held.

Regarding the periodical health examination campaign, Dr. Reik said:

"At a recent meeting of the Hudson County Medical Society, Dr. Waters submitted a new plan for revival of the periodic health examination campaign. The Executive Secretary has volunteered to assist Dr. Waters in the preparation of a moving picture to illustrate his plan, and when ready such picture will be made available to all of the county societies. We intend also to supply the secretaries of all county societies with a list of all moving picture films made available by the American Medical Association, the American College of Surgeons, the American College of Physicians, the United States Government, and some commercial houses that have produced pictures without advertising matter. We would also remind you that the State Society owns projection apparatus for films of both sizes, the standard 35 mm. and the smaller 16 mm., which are at your disposal whenever required."

Radio broadcasts under County Medical Societies were reported as follows:

	Number of Talks
Atlantic County (city) over WPG	14
Bergen County, WBMS and WOR	25
Monmouth County, WCAP	32
Total	71

The Secretary, Dr. J. B. Morrison, reported a membership of 2,709, an increase of 167 over last year. The Secretary reported on contract practice, in Mercer County:

"Mercer County Medical Society has already taken definite action in regard to contract practice. In that county, any physician who engages in any form of contract practice must submit his contract to the component society for its membership in the county society."

Case-lifting was discussed as follows:

"'Case-lifting' has been settled by the Essex County Medical Society. Hereafter, in that county, any physician 'lifting' a case, whether by

(*Continued from page 1122—Adv. xxvi*)

instruction from an Insurance Carrier or not, will have his status as a desirable member of the County Medical Society investigated by the Council. If he is found guilty of case-lifting, he may be read out of the Society."

Graduate Education was described by Dr. S. A. Cosgrove:

"At the annual meeting of the State Society that year, 1927, the then existing Committee on Post-Graduate Education reported that there was no demand among New Jersey physicians for post-graduate instruction, and the House of Delegates accepted the report and discharged the committee."

"An agreement was reached with Rutgers University, in 1929, by which the University should conduct courses for which a fee of thirty dollars should be charged. The courses were given as follows:

"We have had 19 courses conducted in 14 centers, serving practitioners in 16 or more of the 21 counties of the State, and 350 members have subscribed to the courses at full rate of $30 each, the average number of subscribers to each course being 18."

The subjects were as follows:

"'Straight courses' have comprised Newer Drug Therapy, Pediatrics, Gastro-Enterology, General Medicine, Obstetrics, and Gynecology; several 'combination courses' have included Gynecology and Obstetrics; Heart and Kidney Diseases; Gastro-Enterology and Pediatrics; Gastro-Enterology and Pediatrics; Newer Drug Therapy and Fractures."

The certification of specialitis was discussed along the lines proposed by the Second Councilor District meeting, and abstracted on page 928 of the July fifteenth issue of this *Journal.*

Any one reading the minutes would have difficulty in finding exactly what action was taken on the several reports. They were either accepted as a whole by motion made immediately after their reading, or their recommendations were referred to the Business Committee whose report is not contained in the published minutes.

POLIOMYELITIS SERUM IN ILLINOIS

The *Illinois Medical Journal* for August contains the following editorial on poliomyelitis serum

"The Illinois State Department of Public health undertook to make available an adequate supply of convalescent poliomyelitis human serum sufficient to meet all anticipated needs in Illinois At Springfield and Chicago there is now on hand enough of this serum to treat 200 cases It is available free of cost to any physician in the State who will ask for it Infantile paralysis is by far the most important cause of disability among the 16,000 physically handicapped children in Illinois If the convalescent serum will prevent paralysis in these cases, and evidence indicates that it will, the physicians cannot afford to neglect its use when circumstances make possible the obtaining of it Early diagnosis and the administration of convalescent serum prior to the onset of paralytic symptoms are imperative if paralysis is to be prevented

"In all cases where the service is practicable, a physician from the State Department of Public Health who is especially qualified in that field will be detailed upon request to consult with and assist a local physician in connection with the administration of the poliomyelitis convalescent serum

"For physicians who wish to use whole blood therapy for intramuscular administration, the Department has for free distribution a supply of sodium citrate This will keep the blood drawn from the donors from coagulating prior to its use. Whole blood therapy seems to have a value in treating poliomyelitis cases, while its benefit in preventing or aborting measles in children appears to be unquestionable Physicians outside the range of easy and quick transportation facilities might profit by keeping on hand a supply of the sodium citrate for use in emergencies Full instructions concerning the use of this material go out with each package"

FINANCIAL REPORTS OF HOSPITALS IN KANSAS

The August issue of the Journal of the Kansas Medical Society has the following comment on a law recently passed by the Legislature

"All churches, lodges, cemeteries, benevolent, charitable, social and educational organizations which have been incorporated, and which are not organized and operated for pecuniary profit will be affected by a law passed at the last session of the Legislature

"Laws of 1931, Chapter 139, provides that such corporations shall make a report to the secretary of state on or before March 31 of the preceding year, giving name of the corporation, name and address of officers, time of annual meeting and other particulars This report is to be accompanied by a filing fee of one dollar The act took effect *May 28, 1931*, on publication in the session laws, and will make necessary the filing of the report indicated for the year 1931 by such corporations, following the close of the year December 31, and before March 31, next following

"As many of these corporations have been in existence for 30, 40 and even 60 or more years without having been required to render any account of their corporate activities to the State, it is manifest that a very difficult task presents itself to the secretary of state, that of getting in touch with the officers who are responsible for the conduct of the business affairs of these corporations Many charters have been allowed to expire by lapse of time and will have to be renewed before proper report can be filed

"In many cases the title to valuable property such as church, lodge, and school buildings, cemetery lots and the like may be dependent on the validity of these corporation charters or the acts of their corporate officers thereunder"

MILK ALLERGY BOOKLET OFFERED FREE

Allergy is a subject that is earning greater attention from physicians these days because it appears that a number of obscure ailments may be traced to allergic conditions. Food allergy particularly is coming in for attention, since even a partial list of the manifestations of food allergy reads like a patent medicine advertisement.

Because milk is so widely used as a food, milk allergy was deemed of sufficient importance to S.M.A. Corporation for them to prepare a twenty-two page pamphlet on the subject.

The pamphlet takes up such subjects as: what milk allergy is, allergic manifestations, incidence and diagnosis of food allergy, value and technique of skin tests, elimination diets, feeding suggestions, SMACO Non-Allergic Milks, etc., and makes clear that not all allergies are caused by milk and that not all food allergies are milk allergies.

This booklet is offered free of charge to physicians. See page xxi.—*Adv.*

SILVER NITRATE APPLICATORS

Silver Nitrate Applicators are composed of Silver Nitrate 75% and Potassium Nitrate 25%, fused en masse to one end of wooden applicators. This provides a convenient and sanitary way of employing Silver Nitrate medication. The applicators are six inches in length.

The solubility of Silver Nitrate Applicators when coming in contact with moist tissue, causes instantaneous action, and the sanitary provision of using an applicator but once assures a clean, fresh application for each case.

The many uses of Silver Nitrate as a Caustic, Astringent and Hemostatic are simplified by using the Silver Nitrate Applicator without fear of encroaching upon healthy adjacent tissue and causing unnecessary staining and escharotic action.

100 Silver Nitrate Applicators $1.25. See page xxx.—*Adv.*

NEW YORK STATE JOURNAL of MEDICINE

PUBLISHED BY THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

VOL. 31, NO. 18 NEW YORK, N. Y. SEPTEMBER 15, 1931

HIRSCHSPRUNG'S DISEASE: TREATED BY LUMBAR SYMPATHECTOMY

By T. WOOD CLARKE, M.D. and FREDERICK M. MILLER, M.D., UTICA, N. Y.

From St. Elizabeth's Hospital, Utica, N. Y. Read before the Section on Pediatrics, Medical Society of the State of New York, at Syracuse, N. Y., June 3, 1931.

CONGENITAL idiopathic dilatation of the colon, megacolon, giant colon, or Hirschsprung's Disease is a congenital malformation characterized by dilatation of the colon, abdominal distention, obstipation, at times alternating with diarrhoea, emaciation, and general weakness. The earliest recorded case was reported by Parry[1] in 1825, careful studies were made by Hirschsprung[2] in 1886, and complete reviews of the literature by Finney[3] in 1908, and Bartle[4] in 1926. Several hundred cases have been reported.

The theories of the cause of the disease have been nearly as numerous as the authors who have written upon the subject, and may be classified under the headings of congenital, mechanical, inflammatory, hypernutritive, hyponutritive, and neuropathic.

The typical history is that of onset, prior to, or shortly after birth, with rapidly increasing abdominal distention, associated with emaciation and weakness. The obstipation is the most marked occurring in any known disease, bowel movements varying from once a week to once in three months. In one case there was no bowel movement for nine months. There is usually no abdominal pain or vomiting and few symptoms of auto-intoxication other than pallor and weakness, though some have febrile attacks and others such complicatons as pressure symptoms, intestinal ulcerations or obstruction. While some die in childhood, many drag out a miserable existence to old age.

The dilatation of the colon extends from the internal sphincter upwards. Most of the cases are confined to the rectum, sigmoid, and descending colon, but others involve the transverse and ascending colon and even the caecum and appendix.

Medical treatment has consisted of a regulating diet, laxatives, enemata, and the manual removal of scybala. While such measures produce temporary improvement in hospital, the scybala usually reaccumulate after return home.

The surgical treatment, until recently, has consisted of colostomy with artificial anus, or of colectomy. The first procedure necessitates a life of discomfort, and the second has a high mortality, and in many cases the portion of the bowel higher up has enlarged with a return of the symptoms. The most recent surgical suggestion is lumbar sympathectomy.

In 1895, the English physiologists, Langley and Anderson,[5] demonstrated that stimulation of the lumbar sympathetic ganglia causes inhabition of peristalsis with dilatation of the colon and contraction of the internal sphincter.

In 1892, Formad[6] suggested that Hirschsprung's Disease was the result of a neuromuscular defect in a segment of the bowel. This theory was favored by Lennander[7] in 1900 and Hawkins[8] in 1907, the latter suggesting the name he changed to "neuropathic dilatation and hypertrophy of the colon." Pennato[9] in 1902 suggested the cause to be paralysis of a segment of the intestine, and Bing[10] in 1907 believed it to be a lesion of the sympathetic nervous system. Little credence, however, was given to these theories until recent years.

In 1913, Boeke[11] proved that fibres from the sympathetic nervous system run to the voluntary muscles, and in 1915, DeBoer[12] showed that these sympathetic fibres were the cause of muscle tone.

Langelaan[13] in the same year stated that the function of the sympathetic fibres to voluntary muscles was to maintain what he called "plastic tone." Stimulation of the sympathetic nerves to muscles results in the fixation of the muscle in the position in which it happens to be at the time of the stimulation.

In 1924, N. D. Royle,[14] the orthopedic surgeon, and John I. Hunter,[15] professor of anatomy of Sidney, Australia, working together, proved

experimentally that resection of the sympathetic ganglia relieved the spasticity of the extremities in animals in which artificial spastic paralysis had been produced. Royle then performed such an operation on two human patients suffering from spastic paralysis. In the patient with spastic paralysis of the legs from whom Royle excised the rami of the lumbar sympathetic ganglia, he noted complete relief from a long-standing obstinate constipation. These findings have been confirmed in numerous cases since that time.

Hunter further showed that in paralyzed animals in whom the distal portion of the colon was quiescent and dilated, excision of the lumbar ganglia caused immediate resumption of activity of the distal colon and expulsion of feces. He reached the conclusion that an important function of the sympathetic system is to impose a posture on the structure innervated by it, and that section of the sympathetic fibres released this postural state.

In January, 1926, Henry J. Bartle[4] of Philadelphia in a report of a case of Hirschsprung's Disease refers to this work of Royle and Hunter in cases of paralysis and says that after reviewing their work and studying the function of the sympathetic nervous supply of the bowel that "the conclusion is forced upon me that in megacolon we have a condition that very closely resembles in its functional aspect spasticity in centrally paralyzed limb muscles. If this is so, a similar method of treatment would seem rational," and he concludes by saying that Royle's operation "appears to me to be ideally suited to cases of megacolon, or, indeed, even to the obstinate cases of atonic constipation, and when the time comes, unless it can be shown that the premises are faulty, and that the conclusions are illogical, I believe that I shall advise that ramisection be done."

As Dr. Bartle's patient showed improvement under medical treatment, the operation was not performed.[16] The credit, however for first recommending ramisection for megacolon in a published article must be given to Dr. Bartle.

The following year, however, 1927, R. B. Wade and Royle[17] reported in the *Medical Journal of Australia,* a case of Hirschsprung's Disease, in which ramisection of the lumbar sympathetic ganglia was performed on May 20, 1926, with excellent results.

They suggest, following Langelaan's theory, that Hirschsprung's Disease is a condition of postural tone of the colon due to excessive stimulation of the lumbar sympathetics. They believe that the bowel being filled with feces, the sympathetic stimulation inaugurates postural tonic states to fit the increasing intestinal contents, and dilatation results.

In 1928, Judd and Adson[18] of the Mayo Clinic reported two more cases of Hirschsprung's Disease upon which sympathectomy was performed, in 1929 Merle Scott and Morton[19] of Rochester, New York, one case, and in October, 1930, Rankin and Learmouth[20] of the Mayo Clinic, one case, and also one of obstinate constipation. In a recent communication before the Australian College of Surgeons, Wade[21] states that he has performed the operation on thirteen cases of Hirschsprung's Disease "with in the main satisfactory results."

In 1929 and 1930, Learmouth and Markowitz[22] of the Mayo Clinic, by animal experimentation, confirmed the researches of Langley and Anderson,[5] and of Hunter.[15] Among their conclusions are the sections of the lumbar colonic nerve invariably lead to an immediate increase in intracolonic pressure and in the amplitude of the contraction of the colon, and that the internal sphincter derives a certain amount of motor innervation through the lumbar sympathetic outflow.

In their report of their case in October, 1930, Merle Scott and Morton[19] add a contribution by demonstrating in two cases of Hirschsprung's Disease that spinal anesthesia temporarily terminated the motor inertia of the large bowel and caused copious bowel movements. They offer this not only as a further proof that Hirschsprung's Disease is due to a hyperactive inhibitory nerve control in some cases, but they also recommend spinal anesthesia be performed before sympathectomy as a physiological test of sympathetic inhibition to prove whether in any particular case sympathectomy is indicated and can be expected to give the results desired.

The results of the operation of lumbar sympathectomy in the small number of cases in which it has been performed have been uniformally favorable. The patients have shown remarkable improvement in their general health. The abdominal distention has decreased with variable rapidity, and the patients who, previously had suffered from obstipation, report regular bowel movements once or twice a day, usually without the aid of laxatives or enemata. There have been no deaths reported from the operation. No untoward symptoms in reference to other pelvic organs have occurred.

In consideration of the remarkable results that have been attained by others by this new procedure in a condition previously considered almost incurable, and of the small number of cases on record, we feel justified in reporting the following case:

Case R. C., 8 years of age. Admitted to the Pediatric Department of St. Elizabeth Hospital in Utica, New York, on October 25, 1930, referred by Miss Meeder, Herkimer County Agent. The patient was a male child, a twin with four brothers and sisters. The other children were normal. The father died of injuries. The mother was living and well. The boy was born at full term, normal birth. He was nursed for

six months. He has had pertussis, measles, and chickenpox.

The present illness was first noticed at six months of age, when, following an attack of cholera infantum, he became constipated. The abdomen began to enlarge, and has been greatly distended ever since. The distention varied on different days. The constipation has been marked, the patient going for days without bowel movements. This has been partially controlled recently by the daily use of cascara. At times he would pass copious stools containing large masses. There has been no vomiting, no diarrhoea, and no fever. He has always been emaciated, sallow, and very weak.

On admission he was greatly emaciated. The face was pinched, the chest flat, the costal angles flaring, and the abdomen enormously distended and pendulous. The tongue was clean and the tonsils large and spongy. The heart and lungs were normal. The chest measurement was 23 inches. The abdomen was 25½ inches in circumference at the navel, and when the child stood erect, it was markedly pendulous (Fig. 1). Upon exposing the abdomen to the air, a firm hard mass would appear extending diagonally from the right costal border to the left Poupart's ligament. *This was firm and elastic, 15 cm.* in width, resembling in feeling a large bologna sausage. It was tympanitic. After two minutes this would fade away and the abdomen would become comparatively soft, though at all times more tense than normal. This mass was evidently caused by massive contraction of a greatly enlarged colon. During its period of contraction, there was no peristaltic wave demonstrable. The appearance of the colon strongly suggested the condition described by Wade and Royle as postural tone of the colon.

FIGURE 1

The patient one month before operation, and after a thorough emptying of the bowel.

On palpation during periods of relaxation several round masses the size of oranges could be felt in the left iliac fossa, and in the hypogastrium.

On rectal examination the external sphincter was normal, but the internal sphincter was decidedly tight. On passing the internal sphincter,

FIGURE 2

X-rays two months before operation, and after an enema of one gallon of barium solution. The pictures were taken immediately after, ten minutes after, and one hour after the enema, the last being preceded by an effort at movement of the bowels.

the finger entered an enormous cavity and immediately impinged upon a hard scybalous mass at least 10 cm. in diameter.

The reflexes were normal. The musculature was weak and flabby.

The child was kept in the hospital for two months, was given fluid extract cascara, one dram each night by mouth and each morning and night an enema of warm olive oil, 8 ounces, followed in one-half hour by an ss enema. Each day for two weeks a rectal examination was made and large scybalous masses were broken up digitally. After two weeks no more fecal masses formed and he obtained good results from his enemata. His abdominal measurement, after the thorough cleaning out, was 24½ inches.

His urine on admission showed a trace of albumin and a trace of sugar. These never recurred after the first day.

On November third a barium enema was given and *x*-rays taken by Dr. M. T. Powers. One gallon of barium solution was injected with no further discomfort than that caused by the difficulty of keeping his balance on the ball-like abdomen. These pictures (Fig. 2) show an enormously dilated sigmoid, almost spherical in form and occupying practically the entire abdominal cavity and an enlarged descending colon. There were no signs of peristalsis and no haustration, either in the immediate pictures or in those taken 10 minutes later. Half an hour later, after going to stool, the sigmoid was still full, the shadow occupying two-thirds of the abdominal cavity. Apparently what emptying had been possible was from the ascending and transverse colon, the sigmoid still remaining dilated and inert.

After the bowels had been thoroughly emptied, the child weighed 44½ pounds.

On November 26th, one month after admission, and after all scybalous masses had been removed from the bowel, photographs were taken (Fig 3).

At the end of the two months' preoperative care, his bowels had been completely emptied and his general condition seemed proper for operation. His weight at that time was 46 pounds.

The surgical treatment of Hirschsprung's Disease consists in the removal of more or less of the lumbar sympathetic nerves, which act on the musculature of the colon, sigmoid, and anal sphincters.

Just how extensive should be the section and removal of the lumbar sympathetics is a question on which the available literature is not unanimous. Royle and Wade of Australia removed the white ramus of the left first lumbar sympathetic and sectioned the mesial branches to the pre-sacral nerve. Judd and Adson of the Mayo Clinic remove the fourth, third, and second left lumbar ganglia including the main sympathetic trunk, repeating the operation on the right side if the caecum and ascending colon were also involved. Rankin and Learmouth also of the Mayo Clinic, remove the anterior sacral nerve and the inferior mesenteric sympathetic nerves.

Because of the enormously distended abdomen extending upward and causing a bell-shaped contour of the chest, exposure of the site of operation is rendered rather difficult.

The *x*-ray showed that this case had no involvement above the splenic flexure, therefore, a left ganglionectomy and sympathectomy was indicated.

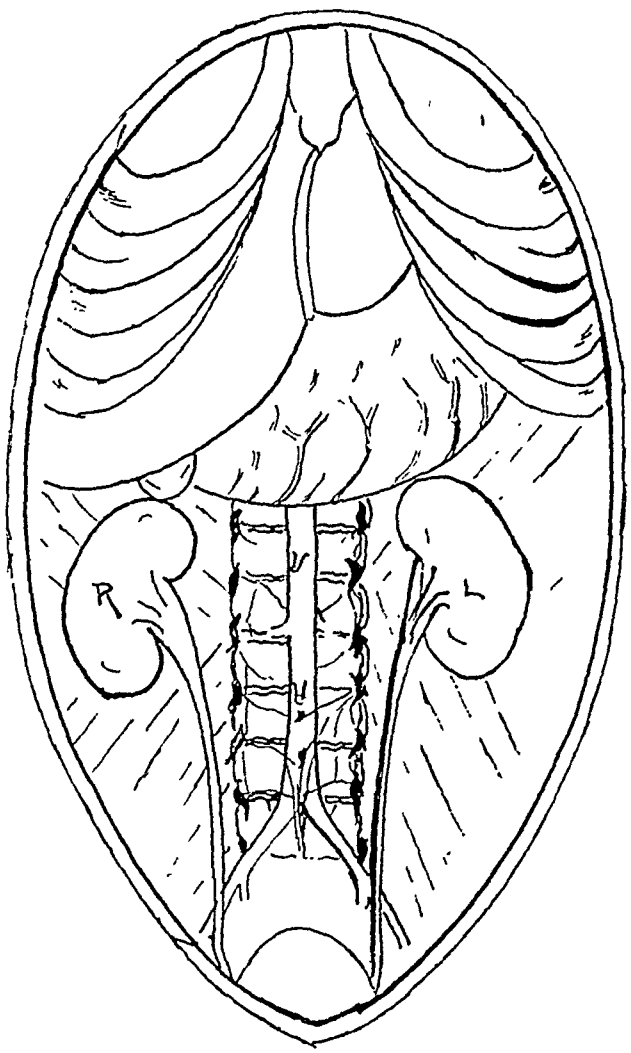

FIGURE 3
Schematic drawing of lumbar sympathetic ganglia and nerve fibres.

Preparation of patient: Three days preoperative soft diet, bowel moved copiously by olive oil and ss enemata. Two days preoperative: Liquid diet, mineral oil oz. i three times a day, five-tenth c.c. pituitrin (surgical) followed in half an hour by ss enema with copious results, preliminary abdominal preparation. One day preoperative: Liquid diet, mineral oil and ss enema.

Morning of operation: Low soap suds enema. Operation December 30, 1930, at St. Elizabeth

Hospital with ether anesthesia. The patient was fastened in extreme Trendelenberg position. An abdominal incision was made seven inches in length through the left rectus muscle, midway to the umbilicus. The greatly distended colon presented itself in the incision. Its walls were thickened and had the appearance of an adult stomach. The intestines were not distended with gas, and owing to the relaxed abdominal walls and abnormally large space in the upper abdomen, it was possible to pack the intestines upward and to the right side, holding them with wet towels. The margins of the abdominal wall were well retracted and with the aid of an electrically lighted retractor a good view was obtained of the posterior peritoneal area. Our landmarks were the promontory of the sacrum, the left ureter, the left iliac artery, and the aorta.

An incision was made through the posterior peritonium three inches in length parallel to the left ureter and one inch lateral to it. The peritoneum was dissected loose from the underlying structures and retracted well across the aorta carrying with it the ureter. This brought into view the inner margin of the psoas muscle, the bodies of the lumbar vertebrae, and the sulcus between, where lie the lumbar ganglia. After removing the loose connective tissue with a dry sponge, the fourth, third, and second lumbar ganglia were exposed lying over the corresponding intervertebral vessels. Beginning with the lowest ganglion, each was carefully lifted up with a blunt hook, the posterior branches cut, and the three removed together with the connecting branches running parallel to the spine. Then with a dry sponge the fibres on the anterior surface of the aorta were removed. There was also a small ganglion on the aorta which was removed. A hot sponge was applied to check the slight oozing. The posterior peritoneum was then closed with a continuous fine catgut suture and the abdominal wall closed without drainage.

The patient showed considerable shock following the operation, which was relieved by heart stimulants, normal saline by hypodermaclysis and enema, and inhalation of oxygen. The pulse remained rapid for two days, otherwise the surgical convalescence was normal.

First day postoperative: Considerable abdominal distention, relieved by pituitrin and enemata.

Third day postoperative: Small bowel movement following a soap suds enema.

Until the patient was out of bed on the fourteenth day the bowels were evacuated daily by soap suds enemata, aided by belladonna and mineral oil by mouth.

The patient left the hospital on February 1, 1931, with orders to continue the belladonna, mineral oil and soap suds enemata, to take regular diet, and report at the hospital in one month.

Photographs were taken of the patient the day before he left the hospital, four weeks after the operation (Fig. 4). These show an upstanding healthy looking child with but slight abdominal distention.

On a return visit on February 17, 1931, seven

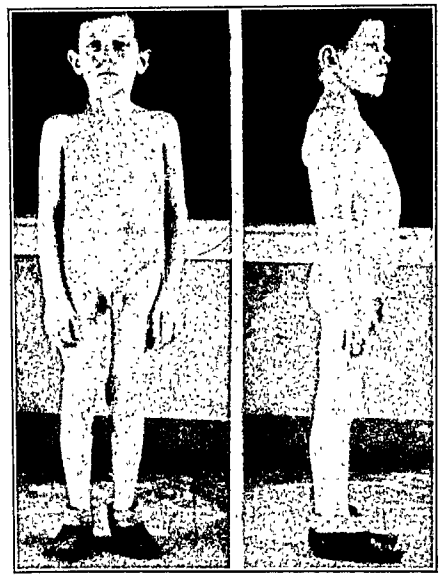

FIGURE 4
The patient five weeks after lumbar sympathectomy.

weeks after operaton, it was learned that the child was feeling well, sleeping well, playing actively, and had a good appetite. He was having two good bowel movements each day. He was receiving cleansing enemata three times a week, and petrolagar, or mineral oil, each day. The abdomen was soft, no distention was noticeable when lying down, but a slight laxity of the abdominal wall below the navel on standing. No masses were felt in the abdomen. The circumference of the abdomen at the navel was 20¾ inches.

A second visit was made on March 17th. At this time it was reported that he was feeling quite well, had had but three enemata during the past month, and that, thought he had discontinued his laxative five days previously, he had continued to have two good bowel movements daily. His appetite was good. He was active and full of life and enjoyed playing with other children.

X-rays were taken on this day by Dr. Powers (Fig. 5). Whereas at the time of the previous *x*-rays, he retained one gallon of barium solu-

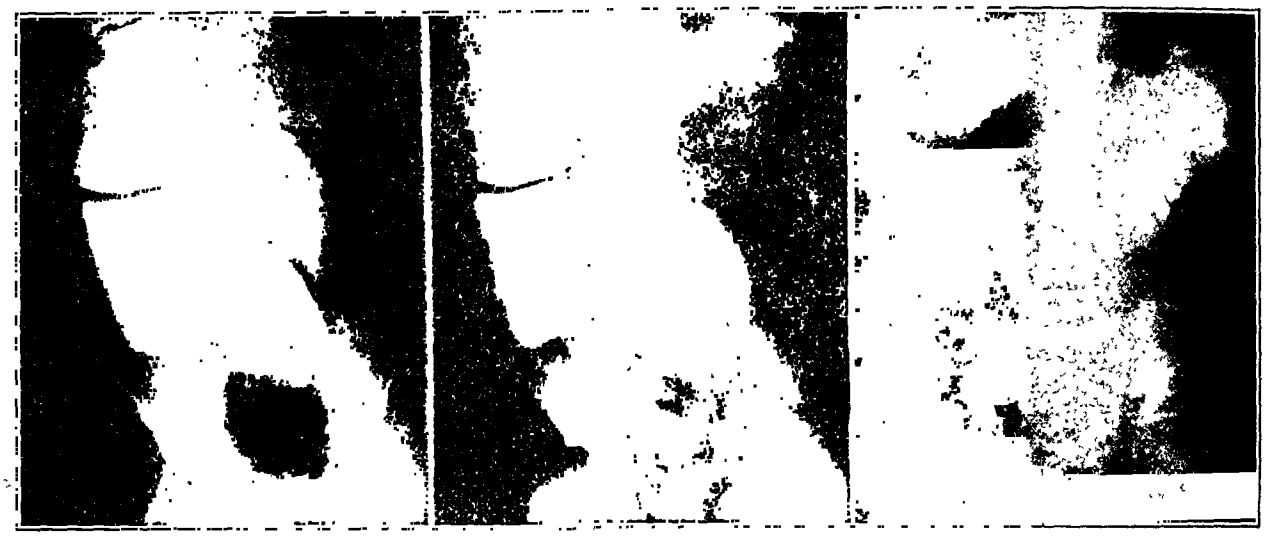

FIGURE 5

X-rays taken two months after the operation, and after an enema of one pint of barium solution, which he retained with difficulty. The pictures were taken immediately after, ten minutes after, and thirty minutes after the barium enema, the last one being preceded by a bowel movement.

tion without discomfort, on this occasion he was not able to retain a quart. The pictures taken immediately after the enema showed a distended sigmoid, but it was tubular, while previously it had been sacular. A picture taken 10 minutes later showed marked haustration and signs of active peristalsis. The picture taken at 30 minutes and after bowel movement showed the bowel completely emptied except for a small quantity of barium at the splenic flexure.

Whereas the first set of pictures showed the sigmoid and descending colon to be an inert sac, the second showed it to be an enlarged but perfectly functioning colon.

When seen next on May 19, 1931, the boy had received no enemata and no laxatives except for a small dose of Agarol each night for two months. His cheeks were rosy. He was active, happy, and except for a slight laxity of the abdominal wall below the navel appeared to be a normal child.

While it may not be justifiable to draw conclusions from a single case, the fact that this case showed such a satisfactory cure in a condition usually considered practically incurable, and that the seventeen other similar operations so far reported in the literature, all showed equally favorable results, we feel that we are justified in our feeling that this new procedure holds forth great hopes in curing Hirschsprung's Disease and restoring these miserable sufferers to practically normal health.

A STUDY OF PROPHYLACTIC VALUE OF VARIOUS ANTIRACHITIC AGENTS*

By ADOLPH G. DE SANCTIS, M.D., and JOHN DORSEY CRAIG, M.D., NEW YORK, N. Y.

From the Pediatric Department, New York Post Graduate Medical School and Hospital.

Preliminary Report

OF late and especially within the past three or four years, medical literature both here and abroad has been more or less flooded with articles dealing with the merits of various antirachitic agents; opposite or contrary views and results have been reported by various authors leaving the reader in somewhat of a maze at the present time. This clinical study was undertaken to determine the prophylactic value of various antirachitic agents in infants rather than in experimental animals: In the final analysis, the merits of any prophylactic or therapeutic agents must be determined by its effect upon the human patient and not upon the experimental animal. I am in no way attempting to detract from the unquestionable value of the experimental work upon the animals but wish to point out that after all, there are marked anatomical and physiological differences between the infant and the rat or guinea pig. If scientific medicine is to be more than the doubtful recording of successive events it must enable us to understand the clinical applications of the discoveries in the laboratory.

Quoting from an editorial in the *Journal of the A. M. A.*[1] *which* states "at present the pathogenesis of rickets seems to be fairly well defined; few of the advances in the science of nutrition have been made with as striking an outcome as have been the case with this disease. The relationship of the inorganic constituents of the diet, the specific effect of cod liver oil, the curative effect of natural and artificial ultra-violet rays and the activiation of ergosterol to antirachitic potency are milestones along the road of progress elucidating the etiology and biochemical relationships of rickets. The novelty of producing a therapeutic agent of photochemical means together with the tremendous potency of viosterol has led to an undue canonization of the material on the part of physicians. Without detracting from its merited value in the treatment of rickets, certain observations raise a question as to the simplicity of the pathogenesis of rickets implied in the current facile use of viosterol. If there exists a complacent belief among some investigators that rickets is due to a deficiency of vitamin D alone, there are others who do not accept such a simple relationship.

It is a well known fact that although cod liver oil and viosterol are extremely efficacious in curing rickets, only the former contains the indespensable vitamin A. Brown and Shohl[2] have indicated clearly that, whereas vitamin D is concerned with the calcification of bones, the retention of calcium and phosphorous in the body is largely a function of the level of these materials in the diet, irrespective of the presence or absence of vitamin D. At first the vitamin A was held to be the fat soluble vitamin, deprivation of which led to rickets and xerophthalmia. Later McCollum showed that vitamin A consisted of a fat soluble portion (vitamin A proper) unstable to heat and oxygen, a deficiency of which leads to xerophthalmia and another fat soluble portion (first called X now called D) which was more stable to heat and oxidation than the former.

It is interesting to note that while D is now commonly known as the antirachitic vitamin, A is never called the anti-xerophthalmic vitamin.

Harris[3] has shown that the problem of growing bone may be analyzed in terms of three distinct processes[1] the growth of cartilage[2] the calcification of cartilage and[3] true bone formation.

Rickets is a disease involving all three processes entering in bone formation. There is an excessive proliferation of cartilage, calcification is defective and the differentiation of true bone is imperfect. If this is so, then not only is vitamin D involved but also the fat soluable A vitamin and to a certain extent the water soluble vitamines. This may explain why comparatively better results have been obtained by cod liver oil (rich in both A & D) than with an equal number of units of D alone in the form of irradiated ergosterol. Another question which may be raised at this time is whether the functions of A & D are not interchangeable in the human body in the presence of certain mineral constituents. It has been definitely shown by several observers that even as many as twice the number of D units in irradiated ergosterol as in cod liver oil do not afford the same protection against rickets. This observation is cercertainly worthy of thorough investigation before the final word can be said.

In this clinical study, the infants have been divided into several groups:

1. Those given cod liver oil—3 teaspoonfuls daily or (1400-1700 Oslo rat Units) (140-170 Steenbock rat units).

2. Those given irradiated ergosterol—100 D—10 drops a day (3000 Oslo rat Units) (300 Steenbock rat Units).

3. Those given irradiated ergosterol—250D—10 drops a day. (7500 Oslo Rat Units) (750 Steenbock Rat Units).

4. Those given irradiated ergosterol—500D—10 drops a day. (15000 Oslo Rat Units) (1500 Steenbock Rat Units).

5. Those given cod liver oil concentrate in tab-

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 3, 1931.

let form 3 tablets a day. (1500 Oslo Rat Units) (150 Steenbock Rat Units).

It will be noted all infants in groups 2, 3 and 4 received more units of D than those in the 1st and 5th groups. That those on 100 D viosterol received twice the number of units of D and those on 250D and 500D irradiated ergosterol received 5 and 10 times as much vitamin D respectively as those on cod liver oil. It is important that this be remembered in comparing results.

This study was started in 1928 and is still being continued. In fact this report is in the nature of a preliminary one. In 1931 and 1932 we intend to use 1000D irradiated ergosterol alone, 250D and 500D irradiated ergosterol with the addition of vitamin A, and 250D and 500D with the addition of phosphorous. Also a more prolonged study of cod liver oil tablet concentrate (A&D) is under way. These studies shall be reported later.

Products Used:

Several good grade cod liver oils were used. An accepted irradiated ergosterol was used in all cases and the cod liver oil in tablet concentrate form is one accepted by the Council of the A.M.A.

Dosage:

As stated before—the cod liver oil was given in a dose of three teaspoonfuls a day—the irradiated ergosterol in doses of 10 drops a day and the tablet concentrate in the dose of three tablets a day.

All infants who received a smaller amount or who did not receive the stated amount daily for at least three months were not included in this study. This necessarily eliminated a great many cases. No premature infants were used.

It must be borne in mind that all infants in the various groups were started on an antirachitic agent at approximately the same age, gained at the normal rate and were kept under observation for approximately the same length of time and during the same seasons; also that the series did not include any infants who were growing extremely rapidly. Various types of feeding were used in all groups but apparently these different methods of feeding had no influence on the results observed. In brief the infants were all similar in age, in duration of time on the experiment, in dietary treatment and in rate of growth.

Interpretation of Clinical Observations:

It is conceded that in the interpretation of clinical observations, there may be a great variation of opinion as to what constitutes clinical rickets. Whenever there was any doubt in interpretation, the case was eliminated. The final examinations were made by at least two well trained physicians, independantly of each other and their observations were charted.

The so-called physiological beading so frequently referred to in the literature, occurring in early infancy was enough to cause elimation of the infant. The congenital and presumably physiologic craniotabes that occurs in early infancy stressed by many authors was excluded.

TABLE No. 1

COMPARATIVE VALUE OF AGENTS USED

	Cod Liver Oil	Viosterol 100D	Viosterol 250D	Viosterol 500D	Cod Liver Oil Concentrate
Children Studied	100	123	128	40	38
Children Completely Protected	97 (97%)	94 (77%)	109 (81½%)	35 (90%)	35 (92½%)

TABLE No. 3

CONDITIONS OF THE EXPERIMENT IN THE FIVE GROUPS

	Cod Liver Oil	Viosterol 100D	Viosterol 250D	Viosterol 500D	Cod Liver Oil Concentrate
Age of Patients	1½-11½ Months	11 Days-11½ Months	2 Weeks-1 Year	3 Weeks-10 Months	1 Month 10½ Months
Average Age When Started	4½ Months	4½ Months	2 Months	3 Months	2½ Months
Average Time on Antirachitic	4¼ Months	4¾ Months	5½ Months	4¼ Months	4½ Months
Dose (Daily)	3 Teaspoonfuls	10 Drops	10 Drops	10 Drops	3 Tablets

As clinical evidence of rickets we included marked occipital craniotabes, moderate or marked costo-chondral beading, groove and flaring of the ribs, epiphyseal enlargement and spasmophilia. Again as all of these infants were under observation for at least three months the final examination was made necessarily at an age at which so-called physiological beading or craniotabes would not be present. No harmful effects or symptoms or signs of hypercalcemia were noted.

Calcium and phosphorous blood determinations were not made except in a few cases because of the refusal of the parents to permit the withdrawal of blood. However as Hess[4] pointed out recently, the level of inorganic phosphate in the blood is not as infallible a criterion of rickets as heretofore believed. He states that the fact that the cure of rickets was independent of the concentration of the inorganic phosphate in the blood, indicates that variation of this constituent cannot be regarded as an essential or inherent feature in the pathogenesis of healing of this disorder. He also emphasizes the fact that the product of calcium times the phosphorous concentration in the blood is not a reliable indicator as to whether or not active rickets is present.

It was not possible to secure an *x*-ray examination in all our cases but in those who were rayed the examination corroborated the clinical finding.

CONCLUSIONS

1. Cod Liver Oil in a dosage of 3 teaspoonfuls a day (about 170 Steenbock Vitamin D Units) prevented rickets in 97 per cent of 100 cases studied.

2. Viosterol 100D—given in 10 drop daily doses (300 Steenbock Units) prevented rickets in 77 per cent of the cases studied.

3. Viosterol 250D—given in 10 drop daily doses (750 Steenbock vitamin D Units) prevented rickets in 81½ per cent of the cases studied.

4. Viosterol 500 D—given in 10 drop doses (1500 Steenbock vitamin D Units) prevented rickets in 90 per cent of the cases studied.

5. Cod Liver Oil in concentrate tablet form-given in doses of 3 tablets daily (150 Steenbock Vitamin D Units) prevented rickets in 92¼ per cent of the cases studied.

From the above observations, we note that in the form of cod liver oil in oil form only 170 units of vitamin D are necessary to protect the infant against rickets; in the tablet concentrate form as many D units are needed whereas when viosterol is given, even 10 times the number of D units does not confer the same immunity against rickets.

If rickets is solely a problem of Vitamin D deficiency, why is it necessary to give so much

more in its pure form (viosterol-D only) than when cod liver oil is given?

As expressed by us[5] in 1930, we still are of the opinion that rickets is not due to a deficiency of Vitamin D alone but that Vitamin A and possibly other factors play an important part in this disease.

WHAT IS DIRECT LARYNGOSCOPY?

By JOSEPH W. MILLER, M.D., NEW YORK, N. Y.

From the department of Laryngology and Per-Oral Endoscopy, Beth Israel Hospital, New York City, Service of Dr. Samuel J. Kopetzky

The question of direct laryngoscopy is not entirely clear in the minds of many practitioners of medicine; and even some otolaryngologists are not entirely sure of the subject. In spite of the tremendous volume of literature written on the subject for the past thirty years, and the marvelous results achieved in thousands of cases, the average physician is still dubious about it and has but a hazy conception of the procedure.

Direct laryngoscopy must be differentiated from tracheo-bronchoscopy. The direct view of the larynx is brought about with a straight rigid tube which is used like a tongue depressor, only with the head in extension. This method has no contra indications and may be performed in every stage of life, even in the new-born, when inspiratory dyspnea makes one suspect trouble in the larynx or its vicinity. With this innocent method we can at once rule out a foreign body in the larynx, laryngeal diphtheria, laryngeal polypi, edema of the glottis, an abscess in the soft tissues about the larynx, and the different forms of paralyses.

Especially in children is this method of great importance and very readily performed because of the softness and flexibility of the neck. Two years ago two cases of laryngeal diphtheria were admitted to the hospital with other diagnoses. Severe dyspnea in both infants led to a direct examination of the larynx. False membranes were found and removed by suction, and the children were injected with anti-toxin and then removed to the Willard Parker Hospital.

Never say the child is too sick for a direct laryngoscopic examination.

The problem is entirely different when one has to do an upper tracheo-bronchoscopy. Here one has to push through the glottis a straight rigid tube and the younger the child the greater the danger of subsequent subglottic edema. This method has several contra indications, such as cardiac decompensation, aneurysm, extreme weakness, and grave dyspnea. But when a foreign body is present anywhere in the tracheo-bronchial tree especially a vegetal foreign substance, there are again no contra indications. And in very young children and infants a tracheotomy should be done at once followed by a lower tracheo-bronchoscopy. Unless this is done, a suppurative tracheo-bronchitis will soon follow the presence of a foreign body, especially the vegetal type with resulting broncho-pneumonia and death.

To recapitulate:—Direct laryngoscopy is a simple innocent procedure in the hands of the trained laryngologist. It has no contra indications and should be performed in every case of inspiratory dyspnea the cause of which is not definitely known. In young children and infants it can be carried out in a few seconds without anesthesia either general or local.

Per-oral tracheo-bronchoscopy is a serious procedure in very young children and infants because of the possibility of post-operative subglottic edema. It has several contra indications such as cardiac decompensation, aneurysm of the aorta, high grade dyspnea, marked asthenia, etc. In case of foreign body in the tracheo-bronchial passages especially the vegetal types there are no contra indications. Such foreign invaders must be removed as soon as possible and in very young children and infants we may have to resort to a lower tracheo-bronchoscopy via tracheotomy wound.

THE PROBLEMS IN THE DIAGNOSIS AND TREATMENT OF TRIGEMINAL NEURALGIA.*

By CHARLES H. FRAZIER, M.D., PHILADELPHIA, PA.

From the Neurosurgical Clinic of the University Hospital, Philadelphia, Pa.

RECENTLY I received this letter from the daughter of an elderly lady.

"My mother has had neuralgia for three years. The pain involves the face, mouth and throat. The severe pains are aggravated by a constant, intense burning in the face and mouth. She has had two deep and three superficial alcoholic injections without relief, and has used six bottles of trichlorethylene without results. The pain seemed unbearable and she was taken to some surgical clinic where the radical operation was performed. Certain areas of her head and face pained all the time she was in the hospital. Lately the pains have been terrible, *worse than before the operation.* Before the operation her eye and nose caused little trouble but since then the pain in them is unbearable. The left eye is badly inflamed, much pus forms and the sight is nearly gone. Mother is too miserable now, she is never free from pain."

The same afternoon I saw in my office a patient, sent by his physician with a diagnosis of tic douloureux, who came with the full expectation of going directly to the hospital for the radical operation. He had been suffering for almost five years, not continuously, but for periods lasting weeks. The pain began in the cheek, beside the nose, spread up just to the inner side of the inner canthus, turned sharply to parallel the supraorbital ridge, thence across the temple to a point in front of the ear. Upon being questioned whether it was worse at night or by day he said it was always worse at night. Once he laid his head on the pillow, the pain began. It was an intense burning pain, associated with a dull ache, unbearable he thought. His wife said she thought he would go out of his head.

If an apology is needed, as might seem warranted by the lack of novelty in the theme, I offer these recent experiences, added to which is the invitation of your President to speak to you on the subject of Trigeminal Neuralgia. I subthis letter and this consultation as my texts. It is evident that there are still misunderstandings and misinterpretations of pain phenomena in the trigeminal zone. How may we classify the various forms of neuralgias of the face for the purpose of this informal discussion.

Speaking now only from my own experience with 2,077 cases, in the analysis of which I have made a very intensive study, I have been able to recognize only five groups. There is the postherpetic neuralgia, easily recognized from the preceding history of herpes zoster. Almost invariably in the distribution of the ophthalmic division, these neuralgias may cause intense suffering. The pain is constant, rather than paroxysmal and may persist for weeks or months until the patient may become quite demoralized. In course of time the painful sensation may be transformed into one of various forms of paresthesias, which, to the patient seem equally distressing. In course of time the various sensory phenomena disappear. In other words, we are dealing with a self-limited disease. What is of practical moment is this: the post-herpetic neuralgia, whether in the distribution of the trigeminus or, as more commonly, in that of the intercostal nerves, is not arrested by any treatment directed to the nerve itself. Alcoholic injection, peripheral section of the nerve, or, as when the pain is in the distribution of the intercostal nerves, section of the posterior spinal root, in my experience has had no influence whatsoever. At best, we can treat these neuralgias only symptomatically until the disease runs its course.

Neuralgia in the afferent system of the facial nerve as originally described by Hunt has distinctive features though it must be an affair of rare occurrence. In my entire series, I have seen but one example of what would fit in to the picture which Hunt has so well described. There is no doubt that the facial nerve has many afferent pathways through its anastomoses with the auditory nerve, with Meckel's and the otic ganglion, through the chorda tympani, with the sensory branch to the auricle, but be that as it may, the pain which may develop in this sensory system is no wise comparable to the paroxysmal pains of trigeminal neuralgia.

In but one instance have I seen glossopharyngeal neuralgia, a type comparable in many respects to tic douloureux in that the pain is paroxysmal and of great intensity, quite comparable in its intensity to that of the major neuralgias. The diagnosis is readily established. The pain is induced by swallowing and is referred to the throat in the region of the tonsil and anterior pillar and radiates to the ear. Intracranial avulsion of the glossopharyngeal nerve and section of the pharyngeal branch of the vagus are said to relieve pain although in the single case under my observation the pain recurred.

Excluding these three types, herpetic neuralgia, neuralgia of the geniculate ganglion, and glossopharyngeal neuralgia, what have we left? There are but two groups: on the one hand, true major trigeminal neuralgia, tic douloureux, the term with which the laity seem more familiar, and, on

* Read before the members of the Clinical Society of the Lenox Hill Hospital, New York, May 8, 1931.

the other, a large miscellaneous group which for want of a better term we call "atypical."

To this miscellaneous group I have given a great deal of thought. The problem has driven me into the realm of speculation and research. What is the cause of these atypical neuralgias: how may they be relieved?

Let me first recite what seem to be their characteristic features, characteristic in their distinction from true trigeminal neuralgia. Differentiation of one from the other is important because the methods of relief for one will be futile in the other. In the vast majority of cases the pain expression of the atypical group is so different from that of tic douloureux that there should be not a scintilla of doubt. What are some of the distinctive features?

In the first place the pain is constant, not paroxysmal. To be sure there are periods of remission, but during the attacks which may last for weeks or months, the pain persists day and night, and if you ask the patient whether it is worse by day or by night, the answer almost invariably is "by night." How different from the true tic when the patient's sleep is usually undisturbed.

As to its distribution, if you take the trouble to chart the painful zones, it becomes at once apparent that the pain does not correspond to the anatomical zones of the trigeminus. It is not within the zone of the second or third division of the trigeminus, in either or both. Furthermore, it extends beyond the boundaries of the trigeminus and spreads into the territory of the occipital nerves or the nerves of the cranial plexuses in the neck, sometimes to the shoulder and arm.

The pain, as I said, is constant, often with periods of exacerbation, but again differing from true "tic" is usually deep-seated, deep in the structures of the cheek, or orbit, or temple. It is not a sharp shooting, lancinating pain, but quite the contrary; the painful sensations are described as burning, as throbbing, as those of pressure, as though the tissues were under great tension and would be torn apart. I have been impressed with the difficulty the patient has in describing the pain. Sometimes I have given the patient a pencil and paper and asked for a minute description of his painful sensations. It is surprising, though he has suffered for years, how difficult the patient finds it to describe his misery.

The patient's reaction to drugs, sedatives of one kind or another, is pertinent to our discussion. The patient with "atypical" neuralgia will derive relief from allonal, from codein, from morphin, many of these cases crave drugs, some are addicts. You may record it as an indisputable fact, incomprehensible as it seems, that drug addiction and trigeminal neuralgia never go together.

Now let us review the histories of the two cases with which I prefaced my address, in the light of these distinctive features. In the case of the old lady, her pain spread into the throat, beyond the distribution of the trigeminus, it was more or less constant, the pain was described as an intense burning and, what is of great diagnostic significance, the pain was not relieved by five alcoholic injections. This is an excellent diagnostic test in doubtful cases and supplies at once an absolute contraindication to operative intervention. Under no circumstances should the surgeon consider operation for, as in the case of our old lady, not only was she not relieved, but as is invariably so, the last state of her case was worse than the first. And to add to her distress, she had evidently developed a corneal ulcer.

And what of the second case? As the gentleman described his pain, I charted it on my trigeminal map. I started in the second division, wandered across the territory of the first division and landed in the zone of the third division. The course of the charted pain established the diagnosis beyond peradventure of doubt. The pains of tic douloureux follow anatomical routes; they dart to the periphery, to the terminal distribution at first of one then a second, rarely a third of the three divisions. They do not wander across zones without respect to the course of the peripheral branches. To clinch the diagnosis, I asked the patient one more question, "Is your pain worse by day or by night?" "Always at night." No further evidence was required.

What of these peculiar pain syndromes, whence do they come, how can they be dispelled? I have analyzed a large series of cases and divided them into groups according to their distribution of pain. But nothing was accomplished by this save to indicate that the pain did not correspond to the trigeminal zones and was therefore not of trigeminal origin. It requires no stretching of the imagination to correlate the pain zones of the atypical neuralgia with the distribution in the region supplied by the branches of the external carotid artery.

Wholly without prejudice I have attempted to understand the so-called Sluder syndrome. I became lost in a maze and I am much afraid that Sluder, interesting and persistent as he was, carried away his syndrome with him when he passed on to other realms. I say this with respect for the man and his work, but it so happens that in my experience with members of a large neuralgia tribe that I have never seen a case in which alcoholization of the sphenopalatine ganglion gave any more relief than injections of sterile water, and I have gone one step farther than Sluder or any of his advocates in having designed and practised an operation for the removal of the sphenopalatine ganglion. When this failed to give relief, I considered the chapter closed.

We had rather an interesting time with one of our patients, a lady of 48 years, referred to us by her physician for operation. As in many of these strangely evasive neuralgias, the doctor comes to

the end of his string and generously delivers up the patient to us, giving as his farewell message assurance that by operation her pain will be relieved. In this case, as in other cases, we made our daily charts of her painful zones. These charts speak for themselves and serve a very useful purpose in that they graphically portray the places to which pain is referred at different hours of the day. You will see how the pain spreads from one division to another and beyond the confines of the trigeminal zone.

We noticed that preceding her attack there was a definite pallor of the affected side of the face. What else could account for this but a vasomotor spasm, a sympathetic phenomenon. If there was any anatomical direction or distribution of pain, it seemed to follow the directions of the vessels, of the branches of the external carotid artery, the temporal and posterior auricular arteries. This gave us a clue and we at once prescribed amyl nitrate for its vasodilating effect. For a time there was definite relief, but after a while the effect of the drugs became less apparent. Is it altogether unreasonable to assume that the sympathetic pathways either themselves or through other nerve fibers accompanying them may be held accountable for the occurrence of pain? In support of this supposition there are the gastric crises, there is the relief of pain following the Leriche periarterial sympathectomy. Foerster of Breslau made some interesting and pertinent observations in patients with paralysis of the extremities; in one case of brachial plexus palsy with total anesthesia in the fingers stimulation of the digital artery with faradic current caused a sticking pain in the little finger; in another the face, following section of the sensory root, was totally anesthetic, yet stimulation of the sympathetic fibers in the carotid artery caused pain in the upper jaw. Numerous other illustrations could be cited definitely to establish a relationship between the sympathetic pathways and pain.

Convinced of this, a few years ago in a series of cases I stripped the periarterial plexus from the carotid vessels and removed the superior cervical sympathetic ganglion. The results on the whole were disappointing. These operations failed because we failed to take into account that some of the pain bearing nerve fibers which accompany the periarterial sympathetic plexuses do not enter the nervous system above the first dorsal segment. There are no white rami above this level, hence it would be reasonable to assume that to interrupt these pain pathways to the face, one must inject or remove the sympathetic ganglia and rami below or at the level of the first thoracic segment.

At last it would seem that our speculation and flirtation with the sympathetic system these past years was beginning to bear fruit. Relief of these atypical neuralgic pains has been obtained by injection and by operations on the cervicodorsal and second thoracic ganglia. (Mixter and White, Archives of Neurology and Psychiatry, May, 1931). The results have not been uniformly good. But there has been complete relief in one case for a period of 12 months. At last it appears we are at the point of solving a perplexing problem. This operation, excision of the first two thoracic ganglia by the Henry technic, must be applied to a larger series of cases before any final pronouncement can be made.

So much for the atypical neuralgias. Major trigeminal neuralgia is an uncommon affection; many of you may never see a single case. An almost daily experience with us, I did not realize how infrequent the opportunities for observation of the general practitioner were until I questioned a colleague with an enormous clinical experience, in the closing years of his career. He had seen but two cases.

Hence, I venture to make a few general remarks, even though they may seem commonplace. Tic douloureux is a clinical entity as specific in its complex as typhoid fever or smallpox. Its ear marks are so easily recognized that there need be no confusion as to the diagnosis. Though prevailing in the decade after the fourth decade, I have seen unquestionable examples between the thirtieth and the fortieth year. I have never operated on an Oriental and only twice upon negroes. Tic douloureux always begins in one division of the trigeminus, never in two and always on one side of the face. It never alternates from one side to the other, it never terminates spontaneously. One of my patients is in her 93rd year. There are no exceptions to these statements as there are none to other of its characteristic features. The pain is shooting, lancinating, tearing, always darting to points in the terminal distribution; horribly intense, as are all root pains. (Consider the crises of tabes.) And between the paroxysms complete freedom; incited by contact with the skin or mucous membranes or by movements of the muscles supplied by the motor division of the fifth. With these exciting factors inoperative sleep is peaceful and uninterrupted. The initial attack may last but a few weeks but as time goes on the attacks become more frequent, the interval shorter and the pain more intense. Eventually, in the course of time, paroxysms may be a daily occurrence.

Subjects of trigeminal neuralgia exhibit the most extraordinary tolerance to pain. There are many paradoxes. Justifiable as it might seem, I have never heard of a case of suicide or even threatened suicide. Only the other day a young married woman with atypical neuralgia upon learning she could not be relieved by operation went from my office to a hotel in your city and jumped out of an eighth story window. As I have said before, the "tic" patient never craves opium or per contra you may write it down as an indisputable fact that if the patient is an opium addict whatever may be the nature of her pain it is not tic douloureux. Morphin, the greatest of

panaceas for pain, has no place in the treatment of this specific neuralgia.

I have become convinced that these patients suffer as much from apprehension of pain as from the pain itself. Though relieved of pain for the time being by an alcoholic injection, their minds are never at rest. Like one exposed in a thunder storm, they fear the next stroke of lightning will fell them.

There remains nothing to complete our knowledge of this disease save its etiology. The clinical course, its characteristic features, the methods of relief, are thoroughly comprehended. But of its origin we are in complete ignorance. That it is not due to any systemic ailment, to any toxic influence, to any focus of irritation we are morally sure.

To what are these fleeting pains due which come and go for years without a vestige of a lesion from the mesencephalic root through the sensory root, Gasserian ganglion to the terminal twigs? As a reasonable hypothesis may we not assume a vasomotor spasm in the vessels supplying the trigeminus. The trigeminal we know to be rich in its sympathetic connections. What else could cause a paroxysmal pain that vanishes as suddenly as it appears, without any structural changes in the ganglion itself unless it be a transitory ischemia. We see in Reynaud's disease an illustration of the pain of vasomotor spasm. Whether pertinent or not to this question, two patients volunteered the information that the pains were always arrested when they had fever. Can we postulate in these febrile attacks a hyperemia which counteracts the tendency to ischemia? It is an interesting speculation.

Accepting vasospasm as a reasonable hypothesis, Lux (*Wiener Klin. Woch.*, Vol. 43, 1930, Part 2, page 1435) applied diathermy in a series of cases. One electrode was applied at the occipital protuberance and two over the eye. By this method he claimed to have obtained relief in a number of cases.

Whatever may be the cause of major trigeminal neuralgia, there is no doubt as to the methods which give relief. I can testify only to the results of alcoholic injection and operations upon the sensory root. In a recent number of the *Journal of the A. M. A.*, Glaser claimed for trichlorethylene relief in 15 per cent of cases so treated. I haven't a single observation to offer in support of the efficacy of this drug.

My views as to the selection of one or the other of the accepted methods are well known. Whether it be an alcoholic injection or the major operation, is left to the patient to decide, after he is informed as to what each means. As a rule, after two or three inections the patient has had enough of injections and petitions you to operate. He dreads the next injection, he is wearied with temporizing, he realizes at last that the injections are only a makeshift; he had hoped against hope that his case would be the exception to the rule.

As a class, I find these patients unusually well informed as to the various methods of treatment. They have discussed the question with other victims, with friends of victims, with their physicians. Oftentimes they have secured articles from the medical press with which they have informed themselves. In many instances they have been misinformed. The operation is dangerous, it is disfiguring, the eyesight may be affected. Some time must be spent in clearing away these misunderstandings.

I shall not weary you with a description of the operation or with its evolution. Since 1901, when Spiller first proposed section of the sensory root as a substitute for resection of the Gasserian ganglion, there have been many refinements, chief among which are conservation of the motor root with the advantages implied, preservation of the ophthalmic portion of the root, and later the selective section of the root dividing only that portion in the distribution of which pain is referred.

Conservation of the ophthalmic portion of the root eliminated for good and all the one complication of the original operation, always a source of anxiety to the operator and patient. I refer to trophic keratitis. Fortunately, pain rarely originates in the first division so that only occasionally is it necessary to sacrifice the entire root.

Are there any contraindications to the operation? Up to the 80th year, I should say none. When a patient is 80 years old or older the expectation of life is short and one or two alcoholic injections over a few years will keep the patient comfortable for the short time that remains.

Is the operation difficult? Yes and no. Having performed the major operation 667 times, I never approach the next one without a feeling that I may encounter conditions that may tax to the limit one's patience and ingenuity. No two of this series seem exactly alike. They say practise makes perfect. Be that as it may, this experience at least has taught me how best to deal with the tantalizing annoyances that one may encounter That we have succeeded in reducing the hazards and the risks to a minimum is a matter of record. We have lost but one patient in the last 390 cases. To the patient harassed by pain, his endurance exhausted, nothing is so comforting as to be told the actual facts, when he faces the surgeon with the inevitable question, "Is the operation dangerous?"

RECENT ADVANCES IN OPHTHALMIC SURGERY*

By WEBB W. WEEKS, M.D., NEW YORK, N. Y.

DURING the past year, changes in technique or new procedures in Ophthalmic Surgery reported by men of various countries, have been read of by most of you and many have tried out these new ideas. If the manner of a new method has been correctly described and properly carried out, it has met with approval by some and been considered a failure by others. Most of the failures I might say, are due to the improper carrying out of the procedure advised, one little step having been altered, or not enough experience has been developed in the doing of a particular operation to assure its success or warrant its condemnation by surgeons trying it.

Many of the procedures are alterations of operations or surgical technique evolved long ago, the basic principal remaining the same. One has to but visit various Clinics to see a different method of carrying out many of the commoner operations, each successful in the hands of this or that surgeon. Yet often, what is considered success by one surgeon is not thought of as such by another. Thus an eye may be straightened and look good but the power of convergence may have been weakened or a caruncle may be drawn backward out of position. The results obtained by plastic surgeons with pedicaled or sliding grafts have perhaps corrected a lid or socket deformity, but scars have been made in the area adjacent where no scars formerly existed.

Each surgeon will vary in his technique of the preparation procedure for an operation and in the after care of an operative case, according to his initial training and the ideas he has gathered by visiting various Clinics and watching men of reputation operate. Then too, from his own operative experience he has formulated his system or method and developed changes which are successful in his hands. These may not be best suited to the position in which another operator finds himself, either as to operative facilities, material, personal skill or temperament. In reviewing operative procedures suggested by foreign surgeons we must ever bear in mind that the standards of many foreign countries are quite different from those by which we gauge our patients and carry on our operative procedures. The authenticity or accuracy of the data, too, may be in many instances questioned. Nevertheless, the ideas tried out and expressed in the communications of the various foreign journals can but keep us alert and thinking. From them successful changes in our own methods may be worked out much to the benefit of our patients.

To review with you, I will go over a number of procedures in technique and of operative procedure which seem logical, practical, worthy of a trial and if carried out corectly, assure success in the hands of a good operator.

Asepsis

First let us consider the matter of skin asepsis.

F. M. Liebermann and M. K. Solovieva, report that brilliant green and malachite green aniline dyes possess excellent bacteriocidal properties for the preparation of the skin and lid margins. They are not inferior to iodine and cause no secondary disagreeable after effects, such as: hyperemia, swelling of the lids and loss of the outer layers of the epithelium. These dyes are easy to procure, cheap and usually used in a 1-1000 distilled water or hypertonic salt solution.

Brilliant green is a triphenylemathane compound from five to ten times as powerful an antiseptic as the perchlorid of mercury. Serum interferes much less with the action of this antiseptic, in addition to its antiseptic properties, brilliant green causes no apparent harm to tissues but rather stimulates the formation of granulation tissue. Brilliant green stains the skin readily, can be removed by spirits, should be applied with the operator wearing rubber gloves. Stains on draperies come out easily with the usual washing. It is considered a strong antiseptic particularly as regards anaerobic micro-organisms. (Gram positive.)

If this be true (I have had no experience with it), it seems worthy of trial.

For asepsis of the conjunctiva and lachrymal sac, Polak has found a new disinfectant in Rivanol (Etho-oxydiamino) which is most efficient in a 1 to 20-000 solution. Usually a 1-2000 solution is used to irrigate the conjunctival sac. He tried out a large number of disinfectants in vitro and found that Bichloride of Mercury and the oxcyanide of Mercury possessed the strongest bacteriocidal properties, the staphlycoccus not surviving in dilutions of 1 to 1-000,000. Incidentally, he found that a saturated solution of Boric Acid controlled the growth of Staphylococcii.

Anesthesia

Nerve block has come into its share of approval—first let us say that of the facial nerve as it is successfully carried out by the injection of 1 c.c. of novocain 2% with adrenalin

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 2, 1931.

in front of the tragus of the ear, just below the zygoma and down to the *neck of the ramus* of the Inferior maxillary bone as advocated by Obrien. This stops orbicular spasm in five minutes. In my hands, this has been eminently satisfactory and successful. Orbital anesthesia as advised by L. Lieberman has a definite place in Ophthalmic surgery. Especially for enucleations, eviscerations, and in operations upon the tender, painful eyeball. A thin 4 cm. needle on a 2 c.c. syringe containing novocain 2% or better a 1-1000 solution of percaine plus adrenalin and a 0.2 c.c. of 1-1000 Rivanol for aseptic purposes, enters the orbit in the lower outer quadrant through the eyelid and is carried backward, upward and inward 3½-4 cm. The solution is slowly injected ahead of the needle to prevent piercing a blood vessel. As advised by Duverger and Green.

This procedure is entirely successful, with no untoward results. Care has to be taken in not injecting too much solution. Some orbits owing to either a small size or to the presence of a relatively large globe, hold less than others. The proptosis resulting puts the lids on a stretch rendering instrumental manipulation difficult and limiting the movements of the eyeball. Some sunken globes are brought forward by this injection so that operative procedure is easier and Lauber of Vienna states that ocular tension is reduced, facilitating the operations for a glaucomatous eye with high tension and favoring lens delivery, there being less likelihood of vitreous prolapse.

It would seem that *Avertin,* or tribromethanol, as a basal general anaesthetic when properly given and watched, offers something worth while in Ophthalmic surgery. Acting in twenty minutes when given rectally, reaching its maximum effect in thirty to forty minutes and lasting one and one-half to two hours with no bad after effects, it does away with the annoying and obstructive ether cone as well as additional hands about the nose and mouth.

It is reported by one western clinic, that ocular tension is quite substantially lowered during anaesthesia with avertin, making it practically impossible to lose vitreous in a cataract extraction.

It has to be given by a skilled anaesthetist and has certain contra-indications such as severe kidney or liver disease and it should not be given in very obese, cachetic or dehydrated patients.

Surgical Instruments

Among the Surgical instruments of note, the eyelid speculum as modified by Guist of Vienna is thought highly of by Ellett and Black. This principally because it lifts the lids away from the eyeball. In my hands, this instrument seems too heavy, cumbersome to insert and remove, and when its thick lid retractors lift the lid away, it presents a difficult way of approach when one is working from above. It was planned for the period when nerve block was not used as much as it is today.

Another instrument which has its appeal, is a needle for the Epilation and transplantation of cilia as devised and used by Kanbai.

Still another useful clamp, is that devised by Lowenstein and used in removing a mucous membrane graft from the lower tip.

Operative Procedures

Perhaps among the operative procedures giving new hope in the desperate cases which for a long time have been given up as impossible for improvement by any procedure may be mentioned—Keratoplasty as done by A. Elschnig of Prague. He reports 144 cases operated upon after the method of Von Hippel, Sr.

In 139 the vision was improved. 113 of these were cases of corneal scarring due to Chemical burns. In 26 cases of Interstitial keratitis, 17 transplants remained clear with visual improvement.

He used careful preoperative antiseptic treatment, nerve block and the superior Rectus bridle suture.

The entire thickness of the cornea is removed from the center of the scarred area if a thin section is desired or from the margin of a thicker one with a Von Hippel trephine. Any prolapse of vitreous is excised. The implant is slipped into place with a spatula and held there by sutures running from above the limbus down over the implant to the limbus below. Both eyes are bandaged. Patient is kept quiet 10 days—first dressing is on the second day—suture removed and atropine instilled. Unoperated eye is left uncovered after 7 days, the operated one only after the 14th day.

It is essential for success that all infective processes must have been inactive for one year. Children under 14 are not suited for this operation.

Cases of Aphakia, increased ocular tension, or where there is a wide flat synechia between the Iris and Cornea, are not to be operated upon.

Another silver lining flashes for a certain number of suitable cases of Spontaneous Detachment of the Retina. Since last reported before this section, nothing much has been added save perhaps more surety as to the type of case to be operated upon. As restated

by Schoenberg. "Those cases of recent date in which the detachment is not too extensive, and there are only a few small tears, so located as to be accessible to the ignipuncture, carefully located and plotted." Lindner has reported 42 cases coming under his observation, 29 of which showed retinal tears and 25 came to operation. 15 of these were considered cured as the retina had remained reattached for six months. 14 of these operated cases were of recent origin, that is, six weeks or under.

He believes that the operative results become progressively poorer after six weeks.

Vogt believes that a presenile or senile change occurs in the eye with a destruction of the vitreous body and a cystoid degeneration in the region of the equator causes the retinal tear. He reports 26 cases operated upon with eleven cures and believes that from 40 to 50% of recent detachments can be cured.

Gonin reports his experience with 250 patients and in more than 300 operations.

1. In 95 per cent of the cases one or several holes were detected where ophthalmoscopic examination is possible.

2. In 10 per cent of these cases the hole was at the ora serrata.

3. In all recent cases when the hole or tear has been closed, cure is immediate, complete and permanent.

4. In older cases, closing the tear stops the detachment and may produce a more or less complete reposition of the retina, but restoration of the vision generally remains incomplete.

5. If the detachment relapses, it is found that the tear has not been completely closed or that there is another tear which had not been previously seen.

6. A recurrence of detachment in a different region of the eye, is due to formation of a new hole in the retina.

Gonin believes 60% of the recent cases can be cured. Against these favorable results one can get an idea of the meaning of them after glancing at the table of other procedures by Stollard.

We have had 10 cases on our service at Bellevue Hospital with but one cure, though I must say that at least eight of these cases were old and showed no tears of the retina.

Rubbrecht brings forward a simple method of localizing a retinal tear. First getting the meridian by sighting along the pupillary edge proxmial and then distal to the tear, placing a suture in this median and carrying it out over the sclera. Allowing 8 mm. for the distance to the ora serrata from the limbus and 1½ mm. for each disc diameter of the tear from the ora serrata a mark with india ink is made on the sclera exposed by reflecting a flap of conjunctiva and Tennon's capsule. At the New York Eye and Ear Infirmary with this mark as a guide a fine needle is inserted into the eye, noting its relation to the tear with the ophthalmoscope, making the igni-puncture accordingly after the subretinal fluid has escaped.

These measurements and methods of plotting are shown by Rupprecht and Schoenberg.

A distinct advance in the technique of Corneal tattooing has been reported and its success is certain if the cases, and precautions advocated by *Pishel* are taken—particularly that of staining with Platinum chloride.

The technique advised, is as follows:

1. Anaesthesia, Cocaine or phenacine without adrenaline.

2. Epithelium carefully scraped off the area to be stained. Area may be stained with fluorescin to determine its outline if it be thoroughly washed off.

3. Wash cornea with sterile water. Hemorrhage must be stopped.

4. A cotton pledget the size of the denuded area, first dipped in 3% platinum chloride is held against the denuded area, being replaced by a fresh one every minute for about five minutes. This pledget should not be dripping wet.

5. Reduction of the platinum chloride with a drop of hydrazine hydrate on the area for 25 seconds, then washed off with sterile water. Color promptly appears.

6. After 5 minutes wash the eye with normal saline and bandage. Vascular leukomas are harder to stain and fade faster.

Worthy of more than passing notice is the procedure for the treatment of spastic or senile entropion, involving the lower eyelid.

As advocated by Terson, Dudinor and Safar, 2-3 c.c. of an 80% alcohol solution in the deep muscle tissue at the temporal orbit margin preceded by 4% novocain.

More recently and specifically, Hughes outlines the following procedure. A hypodermic with 0.3 c.c. of 4% novocain into the outer fibers of the orbicularis muscle extending a distance of 4-5 mm. into the lower eyelid near the margin. Leaving the needle in place, the syringe is replaced with one containing 0.2 to 0.3 c.c. of 95% alcohol (not denatured), which is injected into the same site.

Five cases are reported but since then as many as 12 cases have received this treatment in the Bellevue and New York Eye & Ear Infirmary Clinics, with relief of the entropion.

Of the numerous operations for iridectomy especially when done to relieve the ocular tension in cases of glaucoma, the one suggested by Post has much to commend it. The limbic

incision is similar to the one used by La Grange insuring getting deep into the filtration angle. The tissues in the area of subconjunctiva filtration are disturbed to a minimal degree, giving rise to less scar tissue formation. The iris can be freed at its attachment.

The objection that might be raised, and it occurred in one of the cases I did, is that the ballooning of the conjunctiva and subconjunctival tissues permits of a chance of getting lost when inserting the Iris forceps. Then too, working from the side through a small opening might seem a drawback. But at any time, the conjunctival flap can be freed, turned down and a La Grange sclerectomy be done.

The following steps are done in this procedure:

1. Subconjunctival injection—saline, of upper bulbar conjunctiva.
2. Double fixation below horizontal line.
3. Introduce Graefe knife into conjunctiva at a point about 3 mm. above the upper border of the Limbus in a vertical line with the temporal border of the cornea.
4. The knife enters A. C. directed toward the tip of the nose. Depress handle and counter pressure made at a point which will cause a section of 1/5 of the circumference of the cornea to be made. Complete section upward on a plane with the iris. Point of knife kept subconjunctival at time of exit, turn blade forward, withdraw knife through original conjunctival wound. Conjunctival bleb is still elevated.
5. Enlarge puncture wound of conjunctiva to 4 mm.
6. Slip iris forceps into the a. c. Pupillary border of the iris seized and drawn upward through the limbus incision. Iris is everted. The iris is pulled into the temporal end of the incision. Part exposed is excised. The scissors being introduced subconjunctivally.

Ten cases were reported as having the tension successfully lowered. Dr. Post writes that he has continued to use this method finding it successful in a large percentage of cases of Chronic simple Glaucoma.

Post Operative Treatment

Accustomed as we are to careful dressing and applying a bandage after ocular operations, the reports of Maselinkova and Rabkin as to the open treatment seem most daring and will make most surgeons sceptical of the feasibility of such a plan. Maselinkova reports 115 cases of all kinds, 65 being cataract cases, where no dressing was applied with only a protective wire mask.

Rabkin reports 62 cases so treated.

These men believe that dressings facilitate the growth of organisms by interfering with the natural cleansing of the eye and raising the temperature of the Conjunctival sac. They believe as well, that this method is more comfortable to the patient, is economical, the postoperative phase is shorter and that the complications and unfavorable outcome are no greater than with dressings applied.

PERFORATED PEPTIC ULCER AND SIMULATING CONDITIONS*

By MAX J. SCHROEDER, M.D., NEW YORK, N. Y.

From the Gastro Intestinal Department of the German Polyclinic.

THERE are very few intra-abdominal conditions that require as prompt and proper recognition as does perforated peptic ulcer. Here time, expeditiously utilized, may tip the scale on the side of life.

The cases to be presented are very significant, for every one of them teaches us a lesson never to be forgotten.

Almost every one is familiar with the text book description, but it is the individual variation that adds color to the situation.

Of a number of very interesting cases of perforated peptic ulcer selected, the following to be presented:

Case 1—A. J., patient, machinist by trade, 50 years of age.

Family History: Negative.

Past History: Had a chancre 25 years ago.

For the past 6 years complained in his own words, of gas in the stomach. The patient was too sick to explain in detail what he meant by gas in the stomach.

Chief Complaint: Was sick 3 days before I was called in to see him. Then the story was as follows:

Three days ago began with pain not localized in the abdomen and chest. At the same time had several stools of bright red and black material of which, he said, passed half a liter. Also had several attacks of hamatemesis the same day. Since the onset of illness, that is, three days before, has not had any more bloody stools. Throughout the three days has had one bowel movement, not bloody.

Physical Examination Revealed:

Abdomen rigid throughout, no definite localized tenderness, liver dullness obliterated.

White blood count, 20,400.

Differential 94% poly morphonuclears neutrophiles.

Pre-operative diagnosis was of perforated gastric ulcer.

At operation a perforation found on anterior surface of stomach to the gastric side of the vein associated with peritonitis. Ulcer was 1½ cm. in diameter.

Blood Wasserman report, received after the operation, was 4 plus.

Five days after the operation developed toxic psychosis (luetic).

Tore off dressings and eviscerated about one foot of colon with omentum.

Died 8 days after the operation.

While one cannot prove that the luetic condition was responsible for this ulcer, yet one does see peptic ulcers clear up sooner with anti-luetic treatment in those afflicted with syphilis. It is permissible to contend that we were dealing here with a peptic ulcer brought about by the luetic condition. The rarity of the condition warrants its report.

Case 2—M. B., painter by trade, 55 years of age.

Chief Complaint:

For the past 34 years complained of pain at the ensiform. Six to seven months during the year was free of pain. Pain was relieved by food, ate 6 to 7 times daily, pain came on 2 to 3 hours after food, also at night.

For the past 12 years complained of constant heartburn, even though was on anti-acid diet.

The *x*-ray revealed syndrome complex of duodenal irritation, i.e., hyper-secretion, hyper-peristalsis, hyper-colonic motility and a small gastric residue. In view of history and Roentgen findings, though not direct but yielded indirect evidence of a peptic ulcer, patient was treated accordingly. That the condition was due to lead was ruled out.

About 2 months after his first office visit, he was suddenly awakened by a severe burning pain in the epigastrium which radiated around to the back. No radiation to shoulder or other regions. Vomited bile tinged mucous. Had a bowel evacuation, noticed no change in color of stools.

Urinary symptoms were normal.

Temperature, 99; pulse, 76.

Physical examination revealed: Patient to be very sick.

Abdomen rigid all over, more pronounced on right side.

Tenderness in epigastrium and right lower quadrant.

Rigidity seemed to be involuntary.

Diagnosis before operation: Perforated peptic ulcer.

At operation stomach and duodenum explored and found them to be normal.

Found gall bladder distended, filled with stones, one was at the cystic duct. Gall bladder and stone in cystic duct were removed.

The points of interest here are as follows:

The patient was operated upon about 5 years ago but just a few days ago he consulted me again giving symptoms of peptic ulcer.

Apropos of the past history, clinical picture and operative findings and present condition, is it not permissible to contend as follows:

A. That the patient had a concomitant peptic ulcer and also gall bladder pathology.

B. That the gall stones were silent prior to this attack.

* Read before the East Side Clinical Society, February 10, 1931.

Internal Causes:

1. Foreign body.

2. Thickening of the mucous membrane due to inflammation or new growth.

3. Hyperplasia of the structures in the bronchial wall, sessile or pedunculated malignant or benign.

4. Accumulation of bronchial secretions, of which the consistency is sufficiently tenacious to overcome the effectiveness of the mechanism provided for their expulsion (seen principally in asthma and bronchitis).

All of these disturbances, with the exception of asthma, may be considered as unilateral and should be thought of when a unilateral bronchial disease presents itself clinically.

When and as an obstruction to a bronchus develops, the ingress and egress of air and secretions become more and more impeded. At length a state exists in which the shifting of secretions or the change in the lumen consequent upon the respiratory movement, causes the bronchus to be alternately open and closed at the site of the lesion. The area of lung supplied by the affected bronchus then becomes a closed space during the period of complete occlusion. This brings about a delicately balanced and constantly changing relationship between the air pressures, proximal and distal to the obstruction.

During a complete respiratory phase the following events may then occur. It is simpler to begin with the expiratory movement from the time when the obstruction is complete. The pressure within the closed space swings toward the positive side. As the movement continues the positivity increases until a point is reached at which the pressure is great enough to force the barrier. Air then begins to bubble through and escape with the general current. If the expiratory movement comes to an end, with the chest wall fixed in its then position, air continues to escape until the differences of pressure are sufficiently approximated to fall below the minimum required to pass the obstructing plug. The bronchus again is closed.

An inspiratory movement begins. A negative pressure is created within the closed space and continues to increase until it is great enough to draw air from the outside through the obstruction. If the inspiratory movement then comes to an end, the chest remaining fixed, air again continues to enter until the differences of pressure are sufficiently approximated to fall below the minimum required to pass the obstructing plug.

The phenomenon can generally be observed at the end of a complete expiration, but unless the bronchial wall is rigid as is the case in infiltrative growth the lumen is likely to become patent at any time during inspiration. In some cases, however, it is only at the end of each respiratory phase that the pressure difference is great enough to pass the occlusion.

If a stethoscope is placed upon the chest wall over the area of lung supplied by the affected bronchus there is audible a ronchus varying in character and intensity with the size of the lumen and the type of the obstruction. It then enters the realm of physical signs and may be conveniently called "After Breathing" because it is a movement of air in the inspiratory direction after the end of inspiration and in the expiratory direction after the end of expiration.

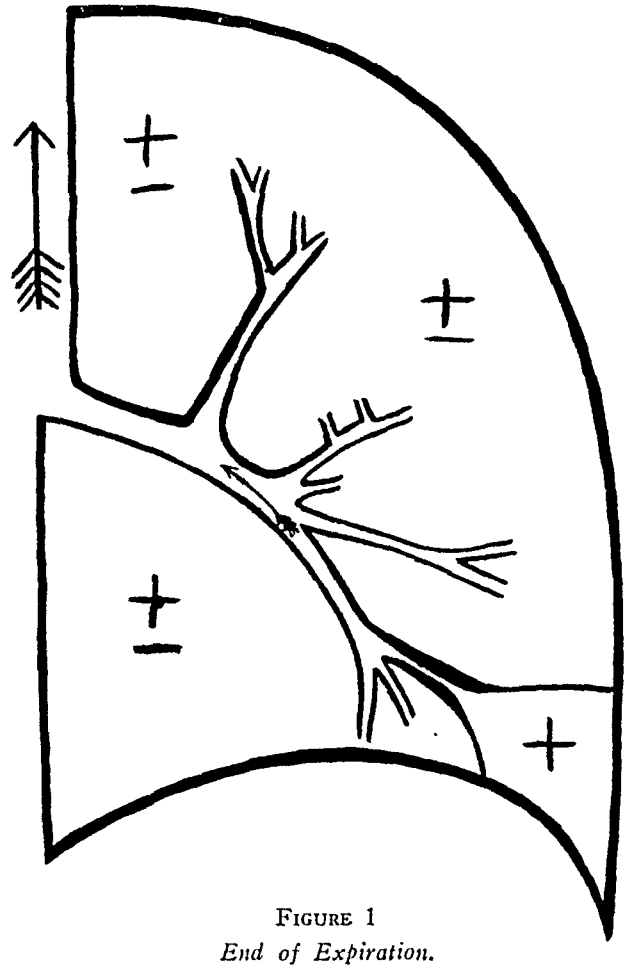

FIGURE 1

End of Expiration.

The diagram shows the relation of the air pressure in the "closed space" to that in the remainder of the lung at the end of expiration, with the air still moving through the mucous-filled narrowing in the expiratory direction. At the end of inspiration the same conditions obtain, except that the pressure in the "closed space" is negative, and the direction of the air current is reversed.

The mechanism involved closely resembles that described by Chevalier Jackson[1] as a "by-pass valve."

RECENT ADVANCES IN THE DIAGNOSIS AND TREATMENT OF CHRONIC DISEASES OF THE NOSE AND THROAT.*

By GEORGE L. TOBEY, JR., M.D., BOSTON, MASS.

THE subject of this presentation precludes any claim of originality on the part of the speaker. The time allotted allows us to but briefly outline the tremendous advances which have recently been made in the understanding of and consequently the treatment of chronic diseases of the nose and throat.

The monumental works of Schaeffer on the embryology of the nose and throat and the more recent work of Negus on the comparative anatomy of the larynx have bridged a yawning chasm and with which all otolaryngologists should be thoroughly familiar.

We are indebted to Mosher for his painstaking and illuminating demonstrations of the surgical anatomy of the nasal sinuses and oesophagus and their practical application in diagnosis and treatment, notably the intranasal approach to the frontal sinus via the aga nasi cells, and a more thorough understanding of the anatomy and pathology of the oesophagus.

Yates has shown us the action of the cilia demonstrating paresis and actual paralysis in the presence of active and chronic infection, thus explaining many of the local phenomena during the course of nasal sinus and pharyngeal infections.

The emphasis placed by the American Board of Otolaryngology on pathology has been reflected by the great increase in articles dealing with the subject appearing in our literature. Without a doubt, more such articles have appeared in the past five years than in the preceding decade.

Foremost among these articles is that of Knowlton and McGregor. It had been the accepted dictum of all laryngologic teaching that when the mucous membrane of an accesory nasal sinus was removed, it was replaced by scar tissue. This belief is constantly quoted as the reason why diseased antral mucosa should not be removed. Knowlton and McGregor have been the first to study the question scientifically. By operating on dogs, they demonstrate by autopsy and histologic sections that in one month's time epithelial replacement is well established and the gland formation begins. Three months afterwards, epithelial replacement is complete, and the canine fossae opening is nearly filled in with bone. In five months, gland formation is well established in the mucous membrane and the muco-periosteum looks almost normal. Sections studied after secondary operations in man, showed the same replacement of the mucous membrane.

McGregor, in the past two years, has collected 24 cases of secondary operations on the accessory sinuses, that confirm this experimental work. This paper will be published at an early date.

Inspired by this work, Coates and Ersner, tried the same experiment on the frontal sinus of the dog and their findings confirmed that of Knowlton and McGregor, showing replacement of the mucous membrane in the frontal sinus, after its surgical removal.

In an attempt to correlate the pathology found in the accessory sinuses with the symptoms, either local or general, Mullin and Ball conclude that no constant finding is present which will enable one to correlate a definite group of symptoms with the pathologic findings. They divide the histologic findings into four groups, according to (1) presence of edema (2) fibrosis (3) leucocytic reaction and (4) glandular hyperplasia or atrophy.

Simpson and Harris likewise studied the histologic sections of their sinus cases and their findings correspond with those of Mullin and Ball.

McGregor studied cysts of the antrum and concludes that they are infectious in origin and occur only in the presence of a pathological process.

We must conclude from the pathological findings to date that the complete removal of the lining membrane of the antra is the logical procedure. We await further observations of expert pathologists.

Consideration of advances in the diagnosis and treatment of the nasal sinuses other than a clearer understanding of pathology and the development of individual technique may best be expressed in the words of D. Campbell Smyth, with whom I am in complete accord:

"The volume of literature on the sinuses is as usual abundant and also as usual contains little that is new. There may be some excuse for men in the small towns in remote sections of the country writing papers containing well known facts, but there can be no excuse for well-known otolaryngologists looked up to by the medical profession continuing to write year after year papers that contain nothing that cannot be found in the most dust-covered textbooks on otolaryngology on the library shelves. The natural inference is that these men have told all that they know, but wish to continue to write.

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 2, 1931.

"The maxillary sinus, probably because, as Mosher once said, it is near the surface and hence easy to get at, is the one about which the most is written. Certainly, this is not due to the fact that trained otolaryngologists should be in any disagreement as to the methods of diagnosis or the proper treatment in diseases of this sinus, for the operative treatment in each case should be well defined in the minds of all well-trained otolaryngologists. It seems to me that there are only two questions concerning the maxillary antrum about which men might logically differ. One of these is the question of using opaque oils as an aid in diagnosis, and the other is whether it is advisable or not to remove all of the lining, diseased and normal, during operation. I feel that these two questions are not settled as yet.

"What I should like to see is more articles on the histology and pathology of the nasal mucous membranes, a practically virgin field. Articles that would add anything to the treatment of osteomyelitis above the orbit would also be of great value."

In treatment of carcinoma of the nasal sinuses and ethmoids, Barnes has combined operation and radiation, using the Moure's incision, cutting away the soft tissues of the cheek, leaving a permanent opening in the face to facilitate immediate radiation and to convert the entire operative field into a surface one which can be inspected for recurrence and further radiation if necessary. The opening may later be closed. He has been successful in 50% of the cases.

The various arguments for and against the different general anesthetics need not be discussed here but if there is any one outstanding rule, a rule which should be applied to the administration of all general anesthetics, it is that the proficiency of the anesthetist and his experience in our special field should be beyond question. If the operation is a nasal, a sinus, a tonsil, or a mastoid operation the anesthetist should be able to cope with the special difficulties that present themselves.

In choosing between local and general, patients of the neurotic type present special problems. The importance of the nervous dread of an operation should not be underestimated even though pain may be entirely eliminated. Anxiety and fear characterize patients of high sensibility and this fear may be increased to the extent of producing a subsequent "traumatic neurosis" in psychopathic patients should they see or hear something that may appear to them alarming or unfavorable during the surgical procedure. Therefore, it would seem that patients of this type are particularly poor subjects for the use of local anesthetics.

The question of pulmonary abscess following tonsillectomies and its development following general or local anesthesia has been the source of more or less study by a number of men. J. Leslie Davis who is a firm adherent of general anesthesia in tonsil operations, stated that recent researches in the field of pulmonary complications has shown that they may develop without regard to whether general or local anesthesia is used or even without any anesthetic. Iglauer in a comprehensive study of the various theories for the development of lung abscess showed that aspired blood was found in the trachea and main bronchi in at least 40% in all cases under general anesthesia and in the trachea of 38% of those done under local anesthesia. If this is true there does not seem to be very much choice between local and general. There is a growing tendency to the more frequent use of local anesthesia in all operations of the nose and throat.

Too much preoperative medication is the rule—it is not necessary to use morphine, hyoscyamin or scopolamin; the barbituric acid derivatives, as sodium amytol, we find to be sufficient, as an adjunct to the local injections of novocain. Avertin is apparently safe, in proper hands, and is finding a definite place in the surgery of the nose and throat.

The usefulness of electrosurgery is becoming more and more evident, not only for the major surgery of malignancy but for numerous minor procedures carried out in the office.

The particular advantages of surgical diathermy are:

1. A comparatively bloodless field of operation, owing to the coagulation of most of the blood vessels traversed.
2. A freedom from local as well as general reaction; pain and sepsis being reduced to a minimum.
3. In malignancy cases the lessening of the risk of dissemination of living cancer cells.
4. An inconspicuous thin scar.

In non-malignant diseases, the indications for its use are numerous.

Epistaxis originating from the anterior portion of the nasal chambers can be very quickly and painlessly stopped by coagulation of the blood vessel. This may be done with the unipolar desiccating current, or with a weak bipolar coagulating current.

Synechiae may be very advantageously eliminated by the use of the cutting current. Remembering past difficulties in preventing synechiae, which have been cut with a knife

or scissors, from reforming, it is very striking to see a broad synechiae completely disappear after the use of the cutting current. The use of packing or splints is no longer necessary.

The hypertrophied inferior turbinates may be cauterized with the use of the diathermy. This can be accomplished in two ways:

1. By the cutting current on the surface of the mucous membrane, or by the use of the coagulating current from a needle introduced into the submucous tissue.

Dr. Lee Hurd of New York has devised a double needle electrode for submucous coagulation of the turbinates. This would seem to be extremely advantageous as the current passes between the two electrodes.

Papilloma springing from the septum may be removed by the use of either the coagulating or desiccating current.

It is extremely advantageous for use in angiomatous tumors of the septum as the bleeding is controlled by the coagulation, and the tumor entirely destroyed, leaving a scar that is not visible. These tumors may be destroyed in toto by one or more treatments, or they may be removed with a snare and the base coagulated.

Diathermy is found to be useful for the destruction of lymphoid collections on the posterior pharyngeal well.

The use of diathermy or coagulation for removal of tonsils in certain selected cases is increasing.

Its use has also been mentioned in treatment of leukoplacia of the buccal mucous membrane.

As in the nose, the removal of papilloma and angioma of the pharyngeal mucous membrane can be accomplished by this method. The chief use in the naso-pharynx seems to be confined to the removal of cictrical adhesions between the soft palate and the posterior pharyngeal wall, and here as in removal of synechia in the nose, it seems to be a very successful method.

Naso-pharyngeal fibroma may be coagulated before removal, or by repeated coagulations may be completely destroyed.

It is open to question as to whether or not the use of radium seeds is not more successful.

The use of this method has been mentioned in treatment of chronic hyperplastic laryngitis, and again in the removal of various non-malignant tumors, such as papilloma, angioma and varix of the cords.

The use of diathermy in malignancy is too well-established to necessitate much discussion at this time. It may be stated that in no way does it supplant the use and benefit of radium. Its application comes principally in operative procedures to be followed by the implantation of radium.

Not only does it control a large part of the hemorrhage but also coagulates the cancer cells and prevents their dispersion.

Those who have experienced the difficulties of doing tracheotomy for malignancy through infiltrated and edematous tissues will appreciate the advantages of using the cutting current as well as the coagulating current.

Tornwald's Disease was the subject of heated discussions for 40 years and gradually lost sight of and rarely diagnosed as such. Dorrance has, through his embryological studies, put this condition on a scientific basis.

A true bursa pharyngea in adults is an independent structure and is not regarded simply as the median recess of the pharyngeal tonsil; it has a definite location for each age of the embryo taking its origin from adhesions of the noto-chord to the pharyngeal entoderm. Clinically it occupies a position in the midline of the pharynx just anterior to the upper border of the superior constrictor muscle. This bursa is often the seat of inflammation and cyst formation.

Cysts of the naso-pharynx should be carefully examined microscopically since most of them, the linings of which contain ciliated epithelium are cysts of the bursa pharynges. It is true that some of these cysts may be of the dermoid type.

We are indebted to St. Clair Thomson, Colledge, Mackenty, Tucker, Lewis and others for the advance in our knowledge of the treatment of cancer of the larynx. St. Clair Thomson and Colledge say that the present position of the use of radium seems to be that it may give promising results in some of the cases which could be more surely and lastingly treated through a laryngofissure, but that, when a laryngectomy is indicated the results are less satisfactory, as a later report shows that in such cases only one out of eleven has survived.

They state in speaking of *x*-ray therapy, that the technique and dosage must always remain in the province of the radiologist, remembering that there are special dangers in the application of *x*-rays to the larynx, which has proved itself to be peculiarly sensitive to their action. *X*-rays have the same effect as radium in producing alteration in the endothelium with obliterative changes in the blood vessels and later telangiectatic appearances in the skin, but if reactions occur, the damage to the larynx can be far more profound than this.

Mackenty is very emphatic in his opposition to the use of radiation in carcinoma of the larynx and gives a striking account of its bad effect.

To quote from Tucker: "Adequate surgical removal is the only treatment worthy of consideration with the hope of cure of cancer of the larynx. The removal of an intrinsic growth by intralaryngeal surgery is not advisable because of the uncertainty of complete removal.

"After early diagnosis, laryngofissure will cure 80 per cent of the anterior intrinsic cases and will give an adequate voice, with no operative mortality, without a mutilating operation. Recurrences following laryngofissure may be amenable to re-operation by laryngofissure, and are always amenable to complete laryngectomy if the patient has been kept under postoperative observation. These patients should be examined by the surgeon who performed the laryngofissure at least every month for the first year."

Complete laryngectomy, according to John Edmund Mackenty, should be done in all intrinsic cases in which there is extensive involvement. Dr. Fielding O. Lewis feels that laryngectomy may also be indicated in extensive cases in which the lesion is extrinsic or mixed, and in other extrinsic varieties, subhyoidpharyngotomy and lateral pharyngotomy.

The use of radium and *x*-ray is now generally conceded to have no place in the treatment of cancer of the larynx, except in some cases as postoperative radiation after laryngofissure of laryngectomy to prevent glandular invasion. It may be used, also, in those cases of cancer of the larynx which are not amenable to surgery because of the location or extent of the growth. Dr. Henry K. Pancoast, from his enormous experience at his clinics at the Philadelphia General and the University of Pennsylvania Hospitals, states: " I no longer use radium in the treatment of laryngeal cancer except in special cases. Cancer of the larynx is not suitable for radium therapy; first, because of the resistant nature of the squamous-cell carcinoma which is the type most often found; second, because of the tendency to necrosis of the laryngeal cartilage after the intensive radiation necessary; third, because of the frequently inaccessible position of the growth.

"Tracheotomy for the relief of dyspnoea with palliative radiation may be advisable for advanced cases."

The recent book—Cancer of the Larynx—by Sir St. Clair Thomson and Lionel Colledge, should be familiar to all otolaryngologists.

It has become apparent during the last few years that the recognition of the importance of bronchoscopy for diagnosis and treatment in disease has resulted in an enormous increase in the proportion of this class of cases as compared with those in which a foreign body is involved, notwithstanding the fact that the actual number of the latter type of cases in which bronchoscopy was used has increased enormously also.

Jackson says: "There is an abundance of clinical evidence at the Bronchoscopic Clinic justifying his opinion that the fundamental factor in all pulmonary pathology is impaired defensive power of the lung due to impaired drainage and deficient aeration. By bronchoscopic drainage we take the load off the cilia and restore spontaneous drainage. With the restoration of aeration and spontaneous drainage we reestablish the defensive powers of the lung."

McCrae summed up his views on bronchoscopy in treatment for abscess of the lung by stating that, when rupture has occurred in a bronchus, bronchoscopy drainage is, without question, the treatment to be tried first. In his judgment, the earlier it is begun the better it is for the patient.

That patients with advanced bronchiectasis can be aided by bronchoscopic drainage is abundantly proved.

Fischer states: "The best initial form of treatment for post-tonsillectomic abscess of the lung, is medical treatment, with or without bronchoscopy; if this fails, continuation of bronchoscopy for a time; if both the foregoing methods are ineffectual some form of operation is indicated, the individual case often being suited for one type of operation rather than another."

Tucker discussed the advantages of bronchoscopy in the diagnosis of suppuration of the lung and pointed out that the bronchoscopist can furnish definite data as to the location and extent of the lesion; the presence of a foreign body in the larger bronchi can be excluded; aid can be given the roentgenologist by the introduction of radiopaque substances into the tracheobronchial tree. This can be carried out most accurately when the substances are introduced bronchoscopically on the fluoroscopic table. Tissue can be removed bronchoscopically for biopsy when deemed advisable. In the treatment of suppuration of the lung, bronchoscopy aids by improving drainage through the aspiration of secretion and local treatment; uncontaminated specimens of secretion may be secured for an autogenous vaccine; structures can be dilated and obstructing granulations removed to improve drainage.

It is now generally acknowledged that carcinoma of the bronchus is more frequently observed than formerly. Whether this represents an actual increase or whether it is a relative increase due to more accurate diagnostic methods cannot be definitely determined.

In Schall's report, a diagnosis of bronchial carcinoma was positively made by bronchoscopy and biopsy in five cases. He concuded that primary carcinoma of the bronchus is not an extremely uncommon disease. Bronchoscopy offered the best means of establishing an early diagnosis of a malignant condition of the bronchi. Patients with obscure conditions of the chest should have the benefit of close cooperation of the thoracic surgeon, internist, roentgenologist and bronchoscopist, acting as a group.

With the advent of bronchoscopy as a means of diagnosis and treatment in cases of pulmonary atelectasis following operation, an entirely different conception of the etiology of this condition was gained. In a study of the records of thirty-three cases of postoperative atelectasis, Lee and others were convinced that three factors have been constant in this group; namely, thick, viscid bronchial secretion, some inhibition of coughing and interference with respiratory movements. Because of the inability of the patient to clear the bronchi of the thick tenacious secretion, it accumulates in the more dependent portions of the bronchial tree until at some point the bronchial lumen is completely occluded. The extent of the atelectatic process depends on the site of the bronchial occlusion; as a result there may occur lobar or massive atelectasis. It has been demonstrated clinically that by making the patient cough, by changing his position (Santee) or by vigorous shaking, an airway can be established past the point of obstruction and the patient may clear the bronchial tree of large masses of secretion. In a number of instances this was ineffective. In eight cases, it was necessary to resort to bronchoscopic aspiration. In each case there was immediate aeration and reinflation of the pulmonary tissue distal to the point of obstruction.

Although the records of the larger clinics show that considerably more than 90 per cent of the peroral endoscopic procedures are performed for conditions other than removal of foreign bodies, there is an actual increase in the number of foreign bodies in the air and food passages. This increase of cases of foreign body is unquestionably the result of more careful examinations by the physician and the roentgenologist and confirms Luis' observations of the now, generally accepted views concerning the necessity of education of the medical profession to consider the presence of a foreign body as a diagnostic possibility in all obscure conditions of the lung.

Smyth's experiences in the use of the fluoroscope for the removal of foreign bodies corroborated the observations of many bronchoscopists. He believed that fluoroscopy should be regarded as a first aid and not as a last resort in the removal of opaque foreign bodies from the bronchial tree. It should be at hand in all cases in which the foreign body has been in the lung for a long period, making the chances of seeing it by direct vision or of feeling it, small. It should be used after one attempt at removal by direct vision has failed, provided the attempt has been made by a competent bronchoscopist, and provided everything possible has been done at the first trial. The mortality is not appreciably raised by this method. The anesthetic should be selected according to the conditions to be combated.

Fluoroscopic removal is preferable to removal of the foreign body by tactile sensation only. Under general anesthesia the excursion of the foreign body can be controlled by having an assistant fix the diaphragm on the side of the intruder. This is of great assistance in the accurate grasping of the intruder. This point, so far as Smyth knew, was new.

Provided no acute condition is present, the duration of bronscoscopy in adults is of secondary importance, the most important thing being the gentleness of the operator, which means lack of any trauma. In other words, the bronchoscopist should not strive primarily for speed, but should rather exercise the greatest patience, and his manipulations should be the most gentle possible. This conclusion is not based on the series of cases reported in this paper alone but rather the result of Smyth's observations in a considerable number of cases of foreign bodies in the air passages, of fairly long duration. Mosher in consideration of the lower end of the oesophagus brings out:

"First, the oesophagus comes to a point at the edge of the left crus, then changes its axis and is confined between the crura until it reaches the stomach. This anatomical formation explains the barium picture of the lower end of the oesophagus, and locates the point of physiological closure on inspiration. Second, forced inspiration causes a more complete closure of the crural angle, and the point of closure of the oesophagus jumps upward a quarter to half an inch, giving the impression that that much of the oesophagus is suddenly amputated. He previously held that this supplemental closure was due to the pressure of the inflated basal lung tips. The findings with the barium striped bag have changed his opinion.

The major clinical conclusions are: As the result of infection transferred from adjacent glands the various components of the oesophageal wall may show at birth a localized or a generalized hypertrophy; ulcer of the oesophagus occurs at or before birth; pouch of the fundus of the stomach is found at birth; infec-

tion about the lower end of the oesophagus can cause a gluing of the fundus of the stomach to the oesophagus and an invagination of the lower end of the eosophagus into the stomach; segmentation is occasionally found in the muscles at the lower end of the oesophagus making the oesophatus at this point structurally weak. The writer has had twenty-five consecutive cases of cardiospasm which show a crural crease in the oesophagus. He believes the crease to be due to a fibrosis of some of the muscle bundles of the crura. It is the result of infection transferred from neighboring organs. The fibrosis of the crural ring is best dilated under fluoroscopic vision. The barium striped bag under manometer control is very efficient for this purpose."

The management of pharyngeo-oesophageal diverticulum has been presented by Lahey who concludes that the two-stage operation is a safe one. Proper dissection of the neck of the sac and implantation of the sac overcomes many of the post-operative difficulties of the operation. He presents a plan for the implantation of small diverticula within the wound, and also one for the excision of the mucous membrane lining the small implanted sacs without reopening the space just in front of the prevertebral fascia.

Allergy

Allergy—meaning altered reactivity of cells and tissues—is the accepted term to designate that condition of hypersensitiveness of certain individuals—roughly 10 per cent—to substances responsible for the production of unpleasant symptoms and lesions; such as, hay-fever, vaso-motor rhinitis, asthma, eczema, migraine, etc. The same term applies not only to the increased or exaggerated activity but also the opposite state of reduced activity.

(Kolmer). It is now known that an antibody is involved in most allergic phenomena or reactions. When the allergic antibody or allergin is in or on cells, the latter are said to be "sensitized" and this constitutes the fundamental state, as it accounts for the altered reactivity of the cells.

When the exciting agent or allergin comes in contact with the antibody or allergin in these sensitized cells, a colloidal shock reaction is believed to occur resulting in the production of lesions and symptoms.

The one and essential difference between normal and allergic persons, therefore, is that the latter produces antibody to pollens, foods and the like while the former (normal) does not, or at least to a detectable degree. In other words, some kinds of antibodies, like antitoxins, afford protection against disease, but in allergy the opposite occurs, in that the antibody is responsible for the disease. Here is a disease that does not appear until antibody is produced or until enough of it has united with certain of the body cells. Why some persons have this capacity for producing allergic antibody to certain substances constitutes the riddle. Natural allergy fortunately is rare and is incidenced by sudden deaths on receiving the first dose of diphtheria or tetanus antitoxin.

The victims of all clinical types of allergy appear either to have inherited a greatly increased capacity for producing allergic antibody or are peculiarly subject to the effects of allergic reactions. Inheritance appears to play an important rôle in many cases of allergy, especially in hay-fever and asthma.

Kolmer believes with Duke that the "physical allergy" due to heat and cold is due to an unstable vaso-motor system.

The proteins of allergens are believed to be the chief sensitizing substances from the clinical standpoint.

A thorough and painstaking history is of the greatest importance in the diagnosis of allergy. Skin tests have proved of great aid. Occasionally skin reactions occur to substances that do not produce symptoms when inhaled or swallowed by the patient. In other words, it would appear that the skin may be sensitive when the mucosa of the respiratory or gastro-intestinal tracts is not. The reverse is sometimes apparent. Skin tests alone, therefore, are not as yet the correct method of diagnosis.

The treatment may be directed along several lines, namely, avoidance or removal of the specific cause, avoidance or removal of contributory causes, specific protein treatment, nonspecific protein treatment and symptomatic treatment.

The outstanding example of specific therapy is of course the treatment with pollen and other protein extracts. Patients showing intolerance to foods may have their tolerance increased by the feeding of minute quantities of the substance in increasing doses.

Treatment with non-specific proteins has a definite place, particularly in cases in which a specific foreign protein cannot be demonstrated as a cause.

Epinephrine is by far the most important drug in the symptomatic treatment of asthma. Patients develop a marked tolerance to the drug.

The internist and the allergist are perhaps not sufficiently alive to the benefits that may accrue from bronchoscopy as to both diagnosis and treatment.

In consideration of nasal and sinus treat-

ment in asthma Tobey propounds three possible hypotheses 1 The nasal pathologic changes are per se the cause of asthma Such an extreme view can hardly be maintained in view of the data obtained from 'follow up" cases Rackemann and Tobey reporting only 5 per cent of cures in 1,074 cases that could be attributed to surgical intervention 2 The nasal pathologic changes are due to the same cause as the asthma and may be considered a part of the asthma —The frequency with which vaso motor rhinitis is coincident with asthma and the similar etiology and pathological changes, particularly the oesinophilia, make this more tenable With this conception, radical surgical intervention is the last procedure to be considered, and then only for the same indications that would hold good if asthma were not present 3 These changes result in a greater permeability to the toxins that cause the asthma This third hypothesis also lends itself to rational treatment

The first hypothesis is arbitrary and in only a few cases can it result in benefit to the patient

Kolmer summarizes as follows

"Hay-fever, asthma and other allergies are still 'strange diseases' concerning which much has been learned and for the victims of which much may be done Desensitization is always worth while under proper conditions if there is at the outset a thorough understanding on the part of both physician and patient that there is as yet no short or 'royal road' to recovery There is much still to be learned concerning etiology and treatment '

RELIEF OF ABDOMINAL PAIN BY SYMPATHETIC RAMISECTION*

By LYMAN G BARTON, JR, M D, PLATTSBURG, N Y

UNTIL knowledge concerning the function of the automatic system in health and disease is much greater than it is at present, therapeutic and surgical procedures on that system will, of necessity, be somewhat empirical and already some procedures which at first seemed promising have proven unsuccessful and have been discarded These cases, reports of which follow, coming as they do in the category of operations based on somewhat indefinite knowledge, are therefore presented largely for the reason that as far as we can determine only five such cases have been to date reported and that in them, thus far, clinical relief has been obtained in what has previously been a hopeless condition

Our interest in ramisectomy for relief of abdominal pain was aroused by an article on the subject by Dr F A C Scrimger of Montreal and the subject, together with a review of the literature was so ably and thoroughly covered by him that much that we have to say is in repetition of his statements The reader is referred to his article for details regarding sympathetic pathways and the technic of ramisection

Historical (largely abstracted from Lewis "Practice of Surgery") In spite of inadequate knowledge of the physiology and pathology of the autonomic system there have already been many surgical procedures instituted some of which have met with a certain degree of success Bodard in 1876 suggested the performance of sympathectomy for Basedow's disease Alexander, of Liverpool, ligated the left vertebral artery in three cases of epilepsy in 1881 and attributed the good results to an interruption of the sympathetic nerve fibers Jaboulay in 1889 proposed isolating the carotid artery from its sympathetic fibers for the treatment of salivary fistula Frank, 1890, suggested cervical sympathectomy for the treatment of *angina pectoris* Jonnesco in 1896 performed cervical sympathectomy for exophthalmic goitre and afterwards for epilepsy, migraine, glaucoma and trifacial neuralgia In 1916 he did the first cervico thoracic sympathectomy for angina pectoris Brown and Coffey (1923), Brunning (1923), Eppinger and Hofer (1923), Diez (1924), Kummel (1923), and Odermat (1923), have all made contributions to the surgery of the sympathetic chain Royle in 1924 did lumbar ramisectomy for spastic paraplegia Fay, 1929, and Grant, 1929, report a great variety of rhizotomies for relief of pain from incurable disease such as cancer White (1929) describes alcohol block of upper dorsal sympathetic rami for relief of pain of angina pectoris Rowntree, Hench and Grist, 1930, report favorable results from sympathetic resection in chronic arthritis Brown and Adson (1929) report favorable results from thoracic and lumbar sympathectomy in vascular diseases of extremities Judd and Adson (1928) report on two cases of congenital idiopathetic dilatation of the colon improved by lumbar sympathectomy However, none of the procedures listed above or any others in the literature except VonGaza's and Scrimger's are directed toward relief of abdominal pain of the type found in the cases which follow

The sense of pain is probably more widely distributed throughout the body than any other one sense It is present throughout the skin, various visceral organs and all the membranes of the

* Read at a meeting of the Fourth District Branch of the Medical Society of the State of New York held at Saranac Lake on October 16 1930

body. The threshold stimulus for pain varies in different parts of the body and it is common knowledge that the pain threshold varies in different individuals and moreover, may vary in the same individual under varying circumstances. While evidence points to the existence of certain pathways for the conduction of pain, histological examination fails to reveal any special end organs for the sense of pain.

Under normal conditions pain perception and localization on the surface of the body is quite accurate whereas pain arising from internal organs is located quite inaccurately, giving rise to what is termed referred or reflected pain. As Head expresses it, "When a painful stimulus is applied to a part of low sensibility in close central connection with a part of much greater sensibility the pain produced is felt in the part of higher sensibility rather than in the part of lower sensibility to which the stimulus was actually applied." Head and others have shown that in many disorders of the viscera there exist segmental areas of hyperesthesia of the skin now termed "Head's zones of cutaneous hyperesthesia."

These zones have been very definitely worked out by Head and MacKenzie and subsequent investigators have varied but little in their findings. Tables showing the relationships between the thoracic and abdominal viscera, the spinal segments and the peripheral nerves are available in many textbooks and will not be reproduced here.

Sensations, interpreted as pain whether arising in the visceral organs themselves or in the connective tissue about the organs or about blood vessels might reach the central nervous system by three possible afferent paths.

1. They might pass by splanchnics to join the cord through the posterior roots of the spinal nerves.
2. They might pass up with the vessels and join the cord by paths as high as the eighth cervical.
3. Or, they might pass through the vagus and phrenic nerves.

Evidence based on the work of Foerster and that of Kappis and Lowen seems to indicate that the pain paths from the abdomen follow the afferent paths of the sympathetic through the posterior roots. The greater number of afferent sympathetic fibers are analagous with somatic neurones, viz., they have a cell body in the posterior root ganglion, a peripheral fiber lying in the white ramus and a central fiber in the posterior root which enters the spinal cord and ends around a posterior horn cell. A smaller number have a cell body in the sympathetic ganglion and a central fiber which terminates in the cell in the root ganglion and so leads impulses to the cord. Others synapsise around the cell in the root of the somatic sensory path. It is on the above evidence that the operation on these cases reported today is based.

VonGaza, who first reported three successful cases of relief of abdominal pain by sectioning of the sympathetic rami was able in thirty instances of *known* abdominal disease accompanied by pain and well-marked Head's zones to obtain by paravertebral novocaine injections relief of pain and anæsthesia of the Head's zone. His localizations differ somewhat from those of Head.

While VonGaza's experimental works in paravertebral novocaine injections were done in cases with *known* abdominal disease, it is in cases characterized by abdominal pain and *lack* of organic disease as demonstrated by previous laparotomy for which sympathetic ramisection is here recommended.

We are all familiar with a certain type of patient who, in spite of all therapeutic procedures including all too often repeated laparotomies with the removal of grossly normal organs, continues to complain of the same pain. These cases are apt to be eventually branded as "neurasthenic" or something equally indefinite but there is one characteristic of these cases which should distinguish them from other patients classed as neurasthenics and that is the fact that they are consistent in their complaint of pain of a like character, in the same location. Their suffering, to them at least, is a real thing and is productive of more disability and distress than some organic condition which might be amenable to known and proven surgical procedures. Hence any operation even though empirical is worth a trial if it offers any hope for improvement.

Theoretically since evidence favors the transmission of pain through the sympathetic chain via the dorsal roots there are at least two procedures which might be tried for the relief of abdominal pain.

1. Paravertebral alcohol injections.
2. Section of the sympathetic rami communicantes.

One would naturally expect the effects of alcohol injections to be less permanent than those resulting from ramisection and moreover anesthesia of the corresponding somatic nerves would result. However, in such conditions as angina pectoris we have been led to believe that alcohol injections bid fair to replace the various operations on the cervical sympathetic.

Ramisection has the advantage of permanency of result without interfering with the function of the corresponding somatic nerves and is useful in that it permits of the severing of sympathetic fibers to a limited area without interruption of fibers from the remainder of the sympathetic chain. Theoretically one should section also one ramus above and one below the segment or segments involved since there is a tendency for afferent impulses to "spill" around adjacent rami; however, this does not seem to be necessary in actual practice.

Acknowledging that ramisection for relief of abdominal pain is as yet an unproven procedure and with the full realization that no definite conclusions can be drawn from so small a number of cases we, nevertheless, are submitting the following reports for whatever interest they may offer.

Incidentally both of these cases met VonGaza's requirements, namely:

1. In both cases any organic pathology had been ruled out by previous laparotomy.

2. The site of the lesions were established by Head's zones of hyperesthesia.

3. Paravertebral novocaine injections preceded the operation and relieved the pain, in each case, for nearly two hours.

Mrs. L. S., New Russia, New York. Referred by Dr. Gersen of Elizabethtown, New York.

White, female, age 19, married 1½ years. Admitted February 21, 1930, discharged March 23, 1930.

Family History: Father 48, alive and well. Mother dead (pneumonia). Two brothers alive and well, one sister alive and well. No hereditary diseases.

Past History: Scarlet fever, pertussis, measles and chickenpox as child. Otherwise well until present illness.

Menstruation began at age 12, always regular, every 28 days until marriage 1½ years ago, since when there has been irregularity. Amount normal, duration two to four days, some clots but not painful, no leucorrhea.

Micturition normal, no dysuria, burning, etc. Appetite poor, digestion poor, no nausea; sense of weight in stomach after eating, eructations of gas at times after eating, no sour stomach, bowels quite regular; never pregnant.

Present Illness: About two years ago she began to have pain in right lower quadrant. Pain referred down front of thigh and "leg ached from hip to knee." Pain "nagging," present most of time with periods at which it became more acute. Worse when she was up and around but not relieved by lying down. Apparently never related to menstruation; not aggragated by constipation. Side felt sore most of time. March 7, 1929 had appendectomy, partial excision right ovary, uterine suspension. Very slight relief for about two months but never "felt right." For past ten months pain has been growing steadily worse and has incapacitated her for all work. No relief from diathermy, vaginal tamponade or organotherapy; about 17 pounds loss of weight in two years.

Physical Examination: General Condition—Temperature 98.3. Pulse rate 80, char. nor.; blood pressure s 110 d 70. Respirations 20, char. normal. Height 5 feet 4 inches; usual weight 138 pounds, present weight, 121 pounds. Nutrition—well developed, fairly nourished. Rather sallow appearance, facial expression and whole bearing show despondency.

Eyes—Pupils react normally, scleræ clear.

Nose and Throat—Negative. Teeth well kept and in good condition.

Neck—No cervical adenopathy. Thyroid not enlarged.

Chest—Equal expansion both sides, breath sounds normal, no rales, no abnormal dullness.

Heart—Percussion outlines normal, apex beat felt in fifth interspace, 1 cm. inside nipple line, action regular, sounds fair quality, A2 = P2, no murmurs.

Abdomen—Level, soft, tympanitic, liver dullness sixth rib to costal margin, edge not felt, spleen not felt, neither kidney felt, no costovertebral tenderness.

Well-healed scar of previous laparotomy; definite tenderness with slight spasm in right lower quadrant about 2 cm. below McBurney's point together with hyperesthesia of skin over area corresponding to distribution of 12th dorsal and first lumbar spinal nerves.

Pelvic Examination: Introitus admits two fingers, no abnormal vaginal discharge, cervix normally situated, normal consistency; uterus normal size and position, freely movable; adnexa normal except that bimanual pressure on right tube causes definite pain which patient states is exactly like the pain of which she complains.

Extremities and reflexes normal.

X-ray of lower dorsal and upper lumbar spine negative.

Laboratory Findings: Urine—Voided specimen February 22, 1930—turbid acid 10.20, albumen 0, sugar 0, bile 0, acetone ++, diacetic 0, Micr-squamous cells +, pus +.

R.B.C.—5,210,000, hemoglobin 95%, *C.* Index .9. Blood Wasserman and Kahn negative.

Progress Record:

February 22 1930, cystoscopic examination—Cystoscopy, bilateral catheterization, right pyelogram.

Findings—The bladder, right kidney and ureter were found normal.

February 23, 1930—Patient suffering from acute coryza. Operation deferred.

March 5, 1930—Paravertebral novocaine injection of 11th and 12th dorsal and first lumbar spinal nerves on right using 6 c.c. 1% novocaine to each nerve. Complete relief of pain with anaesthesia of Head's zone lasting well over two hours.

March 6, 1930—Under general anaesthesia ramisection of 12th dorsal and first lumbar sympathetic rami was performed. Considerable shock following operation and lasting nearly 12 hours. Moderate amount of postoperative discomfort for three or four days. Following this, convalescence

was uneventful and patient was discharged March 23, 1930, wound dry and solid, pain completely relieved.

Report by telephone few days ago to effect that patient has remained perfectly well and has had no return of pain. Slight sense of numbness in right side. Eighteen pounds gain in weight.

Mrs. N. T., Peru New York. Referred by Dr. Sartwell. Admitted July 25, 1930—Discharged August 14, 1930. White, female, age 27.

Family History: Father died at age of 60 of heart trouble. Mother alive and well. Three half brothers living and well. Three half sisters living and well. No hereditary diseases.

Past History: Measles, chickenpox, mumps as child, pneumonia at age of five. Menstruation started at age of 12. Married at age of 15. Three children, ages 9, 7, 2. Since marriage menstruation has been irregular; duration 6 days, amount profuse. Micturition: Quite frequent, with some pain on voiding. Appetite fairly good, digestion fair, bowels regular. Appendectomy, 1918. Uterine suspension, 1919. Tonsillectomy, 1927. Cholecystectomy, 1928. No relief from present pain obtained by any of above operations.

Present Illness: For five or six years has had pain in right kidney region radiating through to right upper quadrant of abdomen. For three years pain was not severe but for past two years has had very severe attacks of pain in same region and some were so severe as to be unrelieved by hypos of morphine. Pain may start in as a dull ache or may start in with a shooting pain. Constant with periods at which it becomes excruciating accompanied by vomiting and nausea. Pain seems worse during menstruation but comes on independent of menses. Patient's last admission to hospital was January 22, 1930, at which time she was suffering from an attack identical with the present one. She was discharged February 1, 1930.

Physical Examination: Fairly well developed, somewhat poorly nourished, sick looking woman. Skin and mucous membranes somewhat pale.

Eyes—Pupils equal, react normally, scleræ clear, no exophthalmus. Nose and throat negative. Tonsils out.

Neck—No enlargement of thyroid, no adenopathy.

Chest—Symmetrical expansion, breath sounds vesicular, no rales, normal percussion note throughout.

Heart—Normal percussion outlines, sounds fair quality, action regular, on murmurs, rate 72.

Abdomen—Level, soft, tympanitic, well-healed scars of previous laparotomies, tenderness throughout whole right side from costal margin down to right lower quadrant and extending well round into right loin. Hyperesthesia of skin over this whole area, slight spasm but no masses or rigidity.

Pelvic examination negative.

Extremities negative. Reflexes active.

Labortary Findings: Urine—voided specimen—turbid, sp. gr. 1016, albumen 0, sugar 0, bile 0, acetone trace, diacetic acid 0. Microscopic—Many squamous cells.

Blood Wassermann negative.

Cystoscopic Findings— January 17, 1930:

Bladder normal. Both ureters easily catheterized. There was a slight increase in the flow from the right side. Aside from that the urine was normal. Pyelogram, right, shows a slight suggestion of dilatation of calyces. Pain caused by the injection was not the same as her other pain. Pelvic examination discloses a moderately enlarged uterus. This finding together with the existence of three abdominal scars, led to the suggestion that tampon treatments plus abdominal support, might be of value.

The day following cystoscopy, patient had another acute attack of pain resembling biliary obstruction.

February 16, 1930:

The right ureter was easily catheterized and normal urine was obtained. A Garceau bougie was inserted to the pelvis without encountering any obstruction.

July 27, 1930:

Paravertebral novocaine injections of 11th and 12th dorsal and first lumbar nerves. This was followed by relief from pain and anesthesia of Head's zones for nearly two hours.

July 29, 1930—Prepared for operation.

July 30, 1930—Section of sympathetic rami communicantes to 10th, 11th and 12th dorsal and first lumbar nerves.

July 31, 1930—Considerable post-operative shock combated in usual manner.

August 14, 1930—Following recovery from immediate post-operative shock patient made an uneventful recovery and was discharged much relieved.

Report of Dr. Sartwell (patient's personal physician) states that patient has continued to gain and to date has had no return of pain. Is now doing light housework.

PSITTACOSIS*

By R. H. RILEY, M.D., BALTIMORE, MD.
From the Maryland State Department of Health, Baltimore, Md

A DISCUSSION of psittacosis, one of the rarer and less known diseases, can hardly be approached without a brief reference to its historical background.

The first recognized epidemic of psittacosis occurred in Ulster, Switzerland, in 1879, in the household of a physician named Ritter. There were 7 cases, with 3 deaths. Four of the patients lived in the same house, one visited the home daily and two handled the birds' cages. In Berne (1882) four people fell ill in a family shortly after the arrival in the home of sick parrots. Little reference is made to the disease until in 1892, in Paris, when in March of that year several successive cases of pneumonia were reported. An investigation of these cases revealed that two bird-fanciers had brought with them in January, 1892, a consignment of 200 parrots from Buenos Aires, and that 300 other parrots had died en route. The homes of these two men became foci of human infection, one giving rise to 22 cases and 6 deaths and the other to 25 cases and 7 deaths. Three other human fatal cases were traced to this consignment of birds, but who had not had contact with the human cases in the two homes.

Dubief (1893) in Paris, reported two family outbreaks which coincided so closely with the arrival of sick parrots as to make a casual connection inevitable. In one family the parrot died five days after arrival. Five people in contact with this bird contracted the disease and 3 died. In the other family, the bird died two days after its arrival in the home; there were two inmates in this household; both contracted the disease and died.

In 1897, there was a limited outbreak in Florence, Italy. In the home of a music professor, 5 persons became ill, of whom 3 died after the arrival in the home of a sick parrot.

Further outbreaks occurred in Prato, Udine and Genoa. A sea captain brought home two parrots; the entire household of four persons contracted psittacosis. A total of 14 cases occurred in Genoa of which 8 were fatal.

In Leipzig, Germany (1882), 3 patients were directly infected from a *dog* that was purchased from a pet shop. The dog also became ill and died. There were several outbreaks in Cologne in 1884. In one home of 10 persons only 1 escaped infection. Four of the 9 patients died. In another home 8 persons became ill and 1 died. In this group 1 was a physician and 1 a nurse. The physician may have contracted his infection from a parrot, but the nurse had no contact with parrots; she contracted the disease from her patients. In another home 5 persons contracted the disease and 1 died. In Krefeld (1899) 11 cases occurred in a hotel, which was connected with sick parrots and finches; 1 of this group died.

In England, prior to the 1929-30 epidemic, 6 cases of psittacosis were reported. During 1929-30, 100 cases of this disease were reported from England; among the fatal cases was the case of Dr. D. L. Thomas, Medical Officer of Health, of the Metropolitan Borough of Stepney.

In the United States psittacosis was first reported by Vickery and Richardson of Boston in 1904; Scott, 1906; McClintock, 1925, and Sailer, 1927.

During 1929-1930 the disease was also reported from Austria, Czecho-Slovakia, Honolulu, France, Denmark, Switzerland, Algeria, Holland and Egypt. In many of the reports it was mentioned that a ship from South America had arrived in the country with sick parrots aboard.

The U. S. Public Health Service reports of the 1929-1930 epidemic in the United States show 74 foci, which gave rise to 169 cases, with 33 deaths, extending from November, 1929, to May, 1930. The cases occurred in fifteen states and the District of Columbia and do not include 16 laboratory infections with 2 deaths, one of which was that of Dr. William Royal Stokes, Director of the Bacteriological Laboratories of the Baltimore City Department of Health.

Psittacosis was first reported to the Maryland State Department of Health on January 6, 1930. Dr. J. Willis Martin reported 3 cases in one family in Annapolis. These cases were investigated by the Department and the U. S. P. H. S. Following these cases, others were soon reported from other sections of the State and Baltimore City.

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 2, 1931.

Symptoms in Birds: The symptoms are those of an acute infection. The bird becomes listless; its plumage is ruffled, it develops a diarrhea; the stools frequently contain blood, and there is usually a discharge from the eyes and nose.

Autopsies on birds dead of psittacosis show enlarged spleens, but microscopic examination does not usually show any distinctive changes. The gastroenteritis is frequently accompanied by a pneumonia. It is stated that parrots suffer from other diseases of this type, which are probably not communicable to man, but they have not at this time been differentiated clinically.

Birds Associated With Human Cases: The majority of human cases of psittacosis reported have been associated with parrots, usually with Brazilian parrots, but gray African parrots have been the apparent cause of infection in some instances. Birds associated with the 1929-1930 outbreak in the United States are known to have some from Brazil, Columbia, Cuba, Nicaragua, Honduras, Germany, Trinidad, Mexico and Japan.

Three of the London cases were due to love birds and one was infected by a canary. In the Argentine series thrushes and an Italian cardinal bird were associated with human cases. In the United States, parrots, love birds, canaries, and parrakeets were responsible for human infections.

Length of Time of Infectivity of Parrots: The majority of human cases of psittacosis have been caused by recently imported birds, but this has not always been so. Several of the London cases became ill three months after the arrival of the parrots.

One other case received a parrot in June, 1929, which had been caught in Africa in November, 1928. The bird did not seem well when caught in November, 1928, and subsequently had slight attacks of diarrhea. In January, 1930, it bit its owner, and the owner became ill with psittacosis on January 19, 1930.

There are numerous instances recorded in which the lapse of time between arrival of the parrot and the occurrence of human cases has been several months. In the present state of knowledge it appears impossible to say how long a newly imported parrot may be a source of danger. It has been suggested that human psittacosis is pneumonia transmitted through the parrot, the bird having been infected, possibly from human sources, passes on the disease once more to man. Scott in Medical Research Council, mentions the susceptibility of parrots to human tuberculosis, but found that primary respiratory tuberculosis in the parrot contracted from man was uncommon, while the birds were more susceptible to the cutaneous form.

The infectivity is not limited to the living bird. It has been conveyed by the corpse of a bird which had died of the disease, also by feathers and excreta. It is difficult to establish definite dates of human contact with sick parrots or fomites, but there appears to be no reason to exclude fomites as a source of infection, especially in a disease which has so many points of similarity with the typhoid group of infections.

Human Case to Case Infection: In considering human case to case infection it is not always possible to exclude contact with sick birds. The first case in the group may be definitely associated with the sick bird; and some days later another who nursed the first case may become ill. Obviously this may be a case to case infection, but if the bird is still in the house or only recently died the possibility of the second case being a bird infection cannot be disregarded. One of the Maryland cases (that of a health department official) presents this aspect. The physician feels that his infection was contracted while examining a human case; still he was in contact with living sick parrots and those that had died of the disease.

There are, however, a sufficient number of clearly defined cases to establish the possibility of human case to case infection. The attendant in the receiving ward of a hospital, a sister and two nurses, and a fellow patient were infected after contact with a patient admitted to the hospital suffering from psittacosis. None of these secondary cases had any contact with sick birds. In Algiers, a sister who nursed 3 cases in another house contracted psittacosis. She had never been in contact with parrots, but she died of psittacosis apparently contracted from the human cases. One of the Baltimore cases (the nurse of Dr. Wm. R. Stokes) had not, so far as could be ascertained, ever had any contact with parrots or other sick birds. She contracted psittacosis and eventually recovered. It is possible, of course, in all the instances cited here and elsewhere, that the secondary cases may have, unknowingly, come in contact with infected material from birds.

House Epidemics: An outstanding characteristic of outbreaks of psittacosis is the occurrence of house epidemics. Gulland remarks that "its occurrence in house epidemics and its relation with parrots are the obvious criteria" of psittacosis. In Ritter's original account the cases were limited to one family. Barros has pointed out "in an infectious pulmonary condition with a general typhoid picture occurring in definite groups, especially family or household groups, we shall have in the future to think of psittacosis, and to ascertain if there has been any association with sick birds."

In the Maryland cases; in the 13 homes which received infectious parrots, 21 cases developed among a total of 49 members of the households. The distribution of these cases according to

household was, 1 case in each of 8 households; 2 cases in each of 2 households; 3 cases in each of 2 households, and 4 cases in 1 household.

In one family in which 2 cases occurred, 2 additional cases developed among visitors known to have been exposed to the same bird.

Among 33 employees of 4 pet shops, known to have had infected birds, 5 cases of psittacosis developed. Four of these cases were among 18 employees of one pet shop.

Age and Sex Groups: In the Maryland outbreak of 36 cases, 5 occurred in those under twenty years of age; 16 in the age group 20 to 39 years; 13 in the age group 40 to 59 years, and 2 cases in persons over 60 years of age. In the Maryland group out of the total of 36 cases, 22 occurred among females and 14 among males.

In 104 cases reported from England in which the ages were known, nearly 50 per cent of the patients were between 40 and 60 years of age and about 60 per cent over 40 years of age. The sexes were affected fairly equally, 57 males and 60 females.

Armstrong reporting 167 cases of known sex which occurred in the United States, states that 105 were females and 62 males, or 63 and 37 per cent of the total, respectively; and further states that the preponderance of cases among females is probably a reflection of the fact that in this country exposures usually occurred in the home where women spend a relatively larger amount of time. The care of birds also commonly falls to women. In the Argentine, Barros brings out the fact that the infection was three times as prevalent among males as females, and attributes the rate to the fact that the infection occurred at exhibits, where men visited more than women.

Clinical Aspects: In man, psittacosis is a severe illness with a high mortality in a limited number of cases; the observed mortality was 20 per cent. The incubation period appears to vary from 8 to 14 days, the average about 10 days and in a few cases it is recorded as long as 21 days.

There seems to have been a uniformity of recorded symptoms of the disease during the 1929-1930 epidemic and it is almost identical with the descriptions of the French epidemics in 1892.

The disease affects all ages and both sexes. The duration of the disease is usually about 2 or 3 weeks, but in a few cases the symptoms have continued for as long as 8 weeks. Convalescence is nearly always protracted and may be interrupted by relapses or by femoral vein thrombosis. Hallucinations are common, and a definite psychosis at times manifests itself weeks after the fever has subsided.

The disease is most often confused with typhoid and influenza. The disease may begin suddenly with a frank chill, chilly sensations, fever and headache, or these symptoms may be preceded for a few days by a general indisposition.

Toward the latter part of the first week, the aspect of the disease becomes more severe. The patient shows signs of profound exhaustion, becomes somnolent and irritable. The fever is at first 100° to 102° F., and tends to rise with irregular remissions to reach 103° to 105° F. during the second week. The pulse is slow in proportion to the temperature. There is intractable headache and insomnia is common. A troublesome paroxysmal cough develops which continues throughout the second week. At first there is little or no expectoration, later this may appear, is thick and at times streaked with blood. Nose bleed is common during the disease.

During the first week signs in the lungs begin to appear, at first a few crepitations or scattered rhonchi, later patches of consolidation develop, which may join to involve the greater part of one or both lungs. One characteristic of the pneumonia is its wandering tendency, so much so as to have been referred to as wandering or creeping pneumonia.

Constipation is the rule, and is obstinate, tenesmus and abdominal discomfort add to the patient's general trouble.

During the second week, the patient may become semi-comatose, often oblivious to his surroundings, and recalled to consciousness with difficulty.

Muttering delirium is often present, and may alternate with periods of restlessness and violent excitement.

Albuminuria is a constant accompaniment, and generally appears during the second week; retention is common—"Rose spots" have been reported in a number of cases in this country and Europe.

The blood count is usually normal during the first few days, but a leucopenia is the rule, the average count being between 3,000 and 5,000.

The temperature generally declines by lysis, and the patient shows signs of improvement, but it is generally at least another week before the patient appears to be out of danger.

Relapses have been frequently reported. The onset of the relapse is with symptoms similar to the original onset, but as a rule milder. The relapses occur as a rule shortly after recovery, but several instances are on record where the relapses occurred 3 weeks after the temperature had returned to normal.

From 15 to 20 per cent of the cases have terminated fatally. Children and young adults withstand the attack better than the old. Death is probably due to pneumonia involvement; the duration of illness from onset to death, ranging from 8 to 15 days.

The Virus of Psittacosis: The discovery by Nocard in 1893 of the B. psittacosis in the bone marrow of a parrot was, up to the 1929-1930 epidemic, the most important contribution on the bacteriology of the disease. The character of Nocard's bacillus, especially its close resemblance to the B. paratyphosus, its pathogenicity for parrots with symptoms resembling those of the sick birds associated with human cases, were in favor of B. psittacosis being accepted as the cause of the disease.

The negative findings since the 1929-1930 epidemic, which resulted from attempts to confirm Nocard's findings, led investigators to demonstrate the fact that the virus of psittacosis belonged to the filterable viruses.

The evidence thus far produced is briefly stated, as showing the causal agent of psittacosis to be a filterable virus—that it is not susceptible of cultivation by ordinary methods in use in bacteriology. It is associated constantly with minute cocco-bacillary bodies which stain with difficulty.

Whether these minute bodies are the virus has not been conclusively proven. They resemble bodies which can be demonstrated in the case of vaccinia and fowl pox viruses, and also bear a close resemblance to Rickettsia.

The number of laboratory infections have caused some investigators to regard the possibility of psittacosis proving to be a further member of the Brucella group.

The investigations thus far conducted show that the virus is present in the mucus discharges from the mouth and nose of human cases and sick birds; It is also present in the excreta and organs of birds ill or dying of the disease. The virus of psittacosis will pass Chamberland and Seitz filters.

Administrative Control: Precautionary measures instituted in Maryland were the quarantine of all birds in pet shops; this regulation continued in force from January 10 to February 21, 1930. Persons owning parrots or other cage birds were advised to pay attention to strict cleanliness of the cage and to the protection of food and water from fowlings of the bird; to remove immediately from contact with healthy birds all birds falling ill; afterward scrubbing and disinfecting the floor of cages and any other article so as to avoid infection of healthy birds; and to avoid fondling and petting of parrots.

From January, 1930, the Governments of those countries in which psittacosis cases appeared prohibited the importation of parrots. As cases of the disease continued to occur in this and other countries, as a result of parrots and other birds being brought in by members of ship crews, it became necessary for the Government to issue regulations to cover this practice.

REPORT OF A STUBBORN CASE OF ACTINOMYCOSIS CLEARED UP BY ELECTRO-COAGULATION

By LEWIS J. SILVERS, M.D., NEW YORK, N. Y.

Read before the North Bronx Medical Society, Oct. 9, 1930

L. H., age 22 years; blood pressure, 110/75; weight, 107¾ pounds; hemoglobin, 70 per cent. Patient had been treated for almost one year for a fungus growth at the base of the tongue, the fauces and the oropharynx. The gradually increasing strength of a silver nitrate solution, applied directly to the growth afforded but temporary relief. Recurrence of growth was evident a few days after each of the caustic topical applications. The ready removal of some small papillomata from the epiglottis by means of electro-coagulation suggested that possibly the same means might destroy the fungoid parasitic growth without injuring the adjacent structures.

Treatment by electro-coagulation was begun on March 10, 1930. The diagnosis of actinomycosis had been made while the patient was under treatment at the Morrisania Hospital, the examination revealing a typical case of mycosis leptothrica of a most persistent strain. The base of each protruding white stem-like growth was touched by the active needle electrode of the biterminal endothermy current. The growth was so abundant and involved so extensive an area that twelve mild doses of electro-coagulation were necessary. The maximum current used was four hundred milliamperes. Fulguration was used in the terminal stages, since the dehydration process is always beneficial in hastening the results of coagulation. At no time did any of the parasitic lesions recur following the coagulation dose. The time required for total cure depended upon two factors, namely: the mildness of the dose and the number of bulbous growths to be treated. Complete destruction of the fungus infestation was accomplished in six weeks.

A RELATIVELY OBSCURE CASE OF CARCINOMA OF THE BREAST

By JOHN BURKE, M.D., BUFFALO, N. Y.

From the Central Park Clinic, Buffalo, N. Y.

WHILE the large series of cases are most valuable in developing the diagnosis and treatment of any lesion, the reporting of single, somewhat obscure cases may be also worth while if only to remind us of the frequent divergence between the textbook picture and actuality. The case reported by Shore[1] is an example in point and one which has led me to report another somewhat similar case.

The patient, a multipara aged 42, consulted me January 5, 1931, because of "a lump in her left chest." This "lump" had been first noticed by the patient in May, 1930, when it was about the size of a robin's egg. As in Shore's case, the patient came for examination solely on the advice of a friend, and not because of any symptoms of disease. There was nothing in the past history to indicate any disturbance before, during or after the several lactations.

The lump was not painful, and at time of examination had apparently not increased in size since its discovery. It was situated just lateral to the anterior axillary line about 8 cm. below the fold of the arm. It was hard, somewhat tender upon palpation, freely movable under the skin and not fixed to the chest wall. The location was so distant laterally from the nipple that it was doubtful, at first, whether or not it belonged to the breast. The remainder of the left breast showed no masses, no tenderness, no nipple retraction or skin dimpling. It was no larger than the right breast. In the left axilla were three palpable, discrete nodes about 2-2 cm. in diameter. These nodes were quite hard, smooth and were apparently not fixed to the surrounding tissues. There were no other abnormalities discovered on physical examination. The past and family history was irrelevant.

Because of the hardness of the mass and of the axillary nodes, a tentative diagnosis of carcinoma was made. In view of the lack of certainty in our minds, preliminary biopsy was suggested. This was performed under gas-oxygen anaesthesia January 6, 1931. The "lump" was removed by sharp dissection, with a liberal margin of microscopically uninvolved tissue.

The specimen obtained was about 2 cm. in diameter, hard and smooth, apparently encapsulated, and to the knife edge presented the supposedly characteristic "feel" of carcinomatous tissue. The cut surface was greyish yellow in color. The report from the State Institute for Malignant Diseases was carcinoma of the breast (frozen section).

With this report in mind the possibility of this mass and the axillary glands being metastases from a distant source was excluded. As no other mass could be demonstrated in the breast it was felt that the mass represented aberrant breast tissue and was probably the primary focus of the carcinoma. Radical breast amputation was performed January 7, 1931. The patient made an uneventful recovery and was discharged to receive prophylactic radiation therapy. Examination six months later, showed no evidence of recurrence.

The breast proper, though examined thoroughly at the State Institute for Malignant Diseases, and further by Dr. J. M. Wainwright[2] in whole breast sections did not show any evidence of malignant disease. The State Institute report was chronic mastitis. The axillary glands showed definite involvement and were reported as metastatic carcinoma.

Discussion:

This case presents several interesting features. From the standpoint of cancer education among the laity here is again a case of a woman of average intelligence who is exposed to the radio and newspaper propaganda of early recognition of cancerous lesions, and who allows a lump in and near her left breast to go unexamined for nine months. The importance of immediate examination of every lump appearing in the feminine *or* masculine breast cannot be sufficiently emphasized.

From the diagnostic point of view, we find a mass almost outside the breast, with no mass, tenderness, skin retraction, etc., in the breast proper, yet with palpably enlarged nodes in the axilla. The diagnosis was definitely established by biopsy.

What the relationship, if any, is between the chronic mastitis found in the breast proper, and the carcinoma in what was apparently aberrant breast tissue is a matter for speculation.

Summary:

A case is presented of a multipara, aged 42 who complained of "a lump in her left side," which was lateral to the anterior axillary line and about 8 cm. below the fold of the arm. Examination showed a breast apparently normal and several enlarged axillary nodes. Biopsy showed the lump to be carcinomatous, and a radical breast amputation was performed. The specimen removed at this time showed chronic mastitis and carcinomatous involvement of the axillary lymph nodes.

FALL ACTIVITIES

The absence of a number of officers and committee chairmen during the summer has compelled a suspension of the inventional activities of the medical society of the State of New York; but already the leaders are back in their offices, and are turning the wheels of activities that will lift the Society to new heights of accomplishment. The Joint Committees on Public Relations and of Public Health and Medical Education held its organization meeting in Albany on September 11th to initiate a study of the proposals of the Governor's Health Commission. The annual meeting of County Secretaries occurs on the day of publication of this Journal; and the round of District Branch meetings begins on September 16, with the third at Sharon Springs.

Preserve your Journals, for they will contain the records of these important activities.

EXPERIENCE VERSUS KNOWLEDGE

When a physician deals with the makers of medical laws, he meets with a fallacy which he must combat, for it has great weight with laymen. This fallacy consists in the belief that an experience of several years in applying a special form of treatment to human beings gives to the chiropractor or other cultists a scientific insight into the inner workings of the human body, so that he can make an accurate estimate of the need of the patient and of the safety and efficiency of his treatments.

How do cultists get their reputation? A patient describes a vague symptom, laboriously searching for the appropriate words and phrases. The cultist expresses those feelings in imposing words, and localizes the trouble in some spot that is accessible to his manipulations. What is vague and mysterious to the patient seems to be clear to the healer. Anyone who does this day after day to the satisfaction of the healer must know what he is talking about;—so argues the layman who listens to the tales of alleged cures of cultists. The people say, "You doctors seem to think that all healing wisdom lies in you. Don't you think that some one else may know something about the body?

The credulity of people generally, even the educated classes, is beyond belief. Many persons who give implicit heed to the directions of their family doctors, will also secretly apply an old household remedy that has helped others under the same apparent conditions.

How much does a healer actually learn from his examinations and manipulations? He learns just about one per cent of what a skilled physician would learn by a procedure similar to that of the cultists; and one-tenth of one per cent of what a skilled doctor would learn by a modern examination such as the doctor ordinarily makes.

What a healer actually learns from his experience is the practical application of the psychology of self assurance.

Say a thing dogmatically and some people will believe you.

Argue with a person and you drive him to oppose you.

The greatest force at the disposal of a doctor in dealing with a legislator is his reputation for good judgment and honesty. A layman is impressed with the opinion held by a worthy doctor, rather than by the reasons and arguments by which the doctor reaches his conclusion.

A cultist is likely to beat a doctor at a public hearing, because he merely states what he has seen and done in his experience, while the doctor puts forth learned arguments clothed in long words which the listeners do not at all comprehend.

There is an old saying "Whatever enters the mind by any other way than that of reason, cannot be removed through the route of reason."

People are still deeply affected by the mysterious and ascribe occult power to those who claim it. These beliefs are more fixed and permanent than those which are induced by reason. Doctors must take these beliefs and prejudices into account in dealing with laymen.

The representatives of medical societies are prone to rely on information and arguments in promoting medical legislation, especially those against the cultists. Physicians have a still more powerful weapon in the mere exhibition of their attitude toward healers and their claims. The fact that a doctor takes the trouble to call on a legislator impresses him more powerfully than long arguments. A dozen doctors making brief calls on a legislator impresses him far more favorably than a dozen pages of convincing arguments.

POLIOMYELITIS CONTROL

Information on the nature and control of poliomyelitis has been spread abroad by leaders in public health by means of newspapers, lectures, and the radio, until everybody has been reached. The spreading of information has been persistent and effective to the extent that the people KNOW what to do with their children during the epidemic. But do the people ACT according to their light? Experience tends to make a public health worker pessimistic.

The people expect the public schools to remain closed, on the theory that parents can control their children more effectively than any other agency. Yet unattended children roam the streets and go to the movies. Now and then a mother of isolated children deliberately goes up the street and asks a close friend not to report her infraction of quarantine.

A mother in a cultured community gave a birthday reception to her five-year-old boy, who vomited at the party; and in the evening his case was diagnosed as positive for poliomyelitis; and now the distracted mothers of the dozen guests are asking how to prevent their exposed children from developing poliomyelitis. These mothers belonged to the intelligent class of the community and yet they were willing to risk the exposure of their children to others.

The medical profession and departments of Health have done all they could to give warning of the danger. What is lacking is the still small voice of conscience in the hearts of the people.

A DUAL MEDICAL SERVICE

There is a tendency toward the establishment of a dual medical service for the people generally. One form of service is that given by individual practitioners, both family doctors and specialists. At the other extreme is the doctor on salary paid by a department of health, a school board, or other official body.

General practitioners form about seventy-five per cent of all physicians, and they dominate medical societies. A criticism of them is that their service is incomplete especially in preventive fields. Much is said and preached and written and broadcast about the possibility of preventing all diseases. This propaganda has aroused the people to expect the doctors to give service which is humanly impossible, not so much on account of the inability of the doctors to give it, as the disinclination of the people to accept and make use of the service.

The remedies proposed for filling in the gaps in the medical service fall into two classes:

1. Family doctors to treat all persons.
2. The state to hire salaried doctors to give the service not now given by family doctors.

The leaders of the Medical Society of the State of New York believe that the family doctors will do their part if the state and local communities will provide the hospitals, social workers, public health nurses, and other agencies necessary for giving a medical service. The legislature has accepted the doctor's point of view by enacting amendments to the Welfare Law and the County Hospital Law under which the communities will supply the hospitals and other means by which the family doctors may treat those in need.

The alternative proposal is that the state should hire doctors on salary to treat the poor and others who are unable to obtain medical service. This plan is being tried extensively by schools, many of which employ full time physicians for examining the pupils. While the statement is usually made that these full time doctors shall make diagnoses only and shall not enter the field of treatment, yet experience shows that it is inevitable that both they and physicians of the departments of health will enter the field of treatment also. If the plan should be carried out to its logical conclusion, there would be a dual system of medical service. Fortunately, the State Medical Society has been able to secure the adoption of plans by which family physicians will give the greater part of the medical service required by the community.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

British Medical Association:—The City of Toronto, Canada was host to the 7th Annual Meeting of the British Medical Association, beginning August 21, 1906. The September, 1906 issue of this Journal says:—

"There is no doubt that Toronto extended a warm welcome to those who were present at the 7th annual meeting of the British Medical Association. Englishmen who had imagined Canada a land of perpetual snow did not seem inclined to don the fur overcoats they had brought with them. Outside the exhibition hall, where under the shade of the trees the thermometer registered 90 degrees, a packing case marked "keep well protected from frost" served as the butt of many jokes. A perspiring visitor from the old country was heard to remark to his Canadian confrere, 'I suppose, doctor, you get a great many interesting cases of yellow fever, enteric and similar tropical diseases in your practice here?' and the gentleman from Texas stated that he was leaving at the end of the first day to go back home where it was cool. In spite of the heat, however, Toronto may be credited with one of the most successful meetings of the British Medical Association that has been held in recent years. There was an unusually large attendance, nearly two thousand registering, and practitioners from the 'States' were very much in evidence. From the Empire State alone there were nearly two hundred representatives. In fact, so large was the delegation from the United States and so prominent was the part they played in the scientific programs, coupled with the fact that Toronto is essentially an American city, that one might almost believe that he was attending a session of the American Medical Association rather than that of the British Medical Association. We are forced to admit, however, that on the whole our British cousins manage their meetings rather better than we do ours.

"Striking was the homage paid on every possible occasion to Dr. Wm. J. Mayo, the president of the American Medical Association. The programs of the various sections were very uneven and some showed lamentable weakness. The general opinion of those who attended both meetings was that the program of the last session of the American Medical Association presented far more material that was of real scientific value. It was somewhat a surprise to hear a few points exploited as 'new,' which had been thoroughly threshed out in American literature several years ago."

MEDICAL PROGRESS

Alcohol as a Cause of a Purulent Urethral Discharge Clinically Resembling Gonorrhea—Eliminating recent gonorrhea from consideration and limiting the subject to cases in which there was no such history, Charles M Whitney states that in an active practice, largely venereal he has seen during the past ten years, since the enactment of the Eighteenth Amendment many more cases of non-specific urethral discharge than prior to that time The patients have been those whose means permitted the purchase of a pure grade of liquor only The form of liquor most commonly taken was synthetic gin, made by using alcohol which was mixed with various proportions of water with the addition of spirits or oil of juniper and glycerin Next to it was Scotch whiskey from supposedly reliable sources To ascertain what impurities, if any were carried over in the distillate, an inquiry was sent to the State Health Department The reply stated that the chemical examination of the bulk of the alcohol submitted by the Police Department was pure ethyl alcohol It seems that the reason urethral irritation is more frequent now than before prohibition may be that there is a higher percentage of alcohol in synthetic gin, or it may be found in the changed drinking habits of the majority of people—the substitution of hard liquor for light wines or beer

In every case in the series that was a history of much drinking The incubation period averaged from twenty-four to forty eight hours The urethral discharge was usually mucoid at first, but soon became mucopurulent or purulent There was no dysuria The urine was nearly always clear, showing a moderate number of shreds in most cases Rectal examination in a few instances showed slight tenderness of the prostate but no swelling Microscopical examination of the urethral discharge showed no gonorrheal organisms throughout the course of the disease The treatment which was most effective consisted in the internal use of citrate of potassium with tincture of hyoscyamus For local use at home the patient was given permanganate of potassium or neosilvol, with office irrigations of nitrate of silver Later gentle prostatic massage and vesicular strippings were apparently of value The condition usually cleared up quite readily The fact that in some of these cases a diagnosis of gonorrhea had been made emphasizes the importance of a microscopical examination in every case in which there is a purulent urethral discharge—*New England Journal of Medicine*, July 2, 1931, ccv, 1

The Rôle of Calcium in Urinary Elimination of Uric Acid—According to P L Violle and P Dufourt, it has recently been shown by certain French investigators that the citric ion forms complex radicals with calcium salts, in which the calcium ion as such is suppressed, and that a part of the plasmatic calcium exists in the form of complex radicals that are biologically inactive, ultrafiltrable, and easily eliminated by the kidneys Thus the citrates may play an important rôle in the urinary elimination of calcium waste that is biologically incapable of utilization by the blood and tissues The authors conceived the idea that an analogous rôle might be played by combinations of uric acid and calcium, that uric acid may serve to change calcium waste into a form more readily eliminable, and that, conversely, a reinforcement of the organic calcium from outside might be capable of combining with the uric acid to form a complex easily excreted Under test conditions they found that individuals with normal blood uric acid eliminate this without any uniform ratio to the calcium eliminated On the other hand, in hyperuricemic individuals in whom no kidney complications existed they found a remarkable constancy of this ratio, hence they think that the uric acid calcium combination may explain the clinical tolerance of this form of hyperuricemia In gouty hyperuricemia the ratio is again very variable, according to the precise moment in the attack At the peak of the crisis and after it, the ratio of uric acid to calcium tends to be lowered, chiefly by means of an increase of calcium

This seems to be a favorable phenomenon, indicating increased facility of uric acid elimination and a passing off of the attack It seems reasonable to assume, as a working hypothesis, that there exists a complex combination between uric acid and plasmatic calcium, characterized by facility of excretion In such case, the administration of calcium in a form capable of combination such for example as calcium lactate which the authors used, would re establish for the time being conditions favorable for elimination, by lowering the uric acid calcium quotient It appears that in acute attacks of gout the organism tries to utilize to the utmost its limited resources of combinable calcium and thus to produce that combination that is easily excretable If it cannot find the requisite calcium it is forced to make other combinations the clinical symptoms of which betray the difficulty it encounters in the task—*Bulletin de l'Academie de Medecine*, June 9, 1931

Sport Injuries and Their Treatment.—C. B. Heald, writing in the *Practitioner,* July, 1931, cxxvii, 1, says the man or woman who can enjoy a strenuous day's sport relies upon six principal factors: (1) the integrity of his framework—bones and ligaments; (2) his power unit—the tone and contractile power of his muscles; (3) his lubricating system—synovial membranes and bursae; (4) his scavenging system—lymph channels and glands and skin; (5) and (6) his coordinating supply service—blood and nerves. Injury to the bony framework requires that attention be given to the other systems. During the first stage the principal requirement is rest—support or fixation. The area can be brought rapidly to the second stage by Mennel's glucokinesis, a new form of sedative massage, and small doses of direct current. If these special physical measures are not available, pain and spasm can be relieved by glycerin and belladonna liniment applied on lint for twenty-four to forty-eight hours. Aspirin should be given in powdered form or the tablet should be sucked slowly. The value of massage, passive movements, resisted movements and reeducative movements is well known, but too little use is made of the Smart-Bristow coil, which can be used in many valuable ways to recondition injured and debilitated muscles. Its application should be continued until the injured limb is at least equal to the uninjured one in circumference, and preferably until it is larger. In the treatment of synovial membranes and bursae, the use of electrical currents and massage requires care and special technique if the condition is not to be made rapidly worse. There seems to be no doubt that variations in temperature are helpful. The recently introduced "elastoplast," a modified form of Unna's paste on an elastic bandage, is valuable in supporting parts where there is synovial effusion. In traumatic bursitis, the only method which has yielded a high percentage of successful results in the author's hands is the giving of a succession of erythema doses with the Kromayer lamp, every three to five days, to small areas of skin over the bursa. This treatment is almost specific for subdeltoid bursitis. The lymph flow is aided by massage and other physical methods. A simple and valuable technique is for the masseuse to wear rubber gloves and over them cotton gloves connected with a Bristow coil by means of a flexible electrode on the back of each hand. The gloves are soaked in warm soap solution and the hands can be used as electrodes while they carry out the movements of massage. As everything depends upon nutrition and nerve supply, these must never be forgotten in the treatment of injuries.

Inoculation Malaria as Cause of Congenital Malaria.—H. Schadow, writing in the *Münchener medizinische Wochenschrift* of June 5, 1931, describes the case of a newborn male infant who developed characteristic signs of malaria in the third week of extrauterine life. The finding of plasmodia of tertian type in the red blood corpuscles made all doubt of the nature of the infection impossible. The tumor of the spleen was enormous, and the child's condition became so grave that only the administration of two blood transfusions with a long course of quinine over a period of twelve weeks finally restored him to health. The child had been separated from the mother immediately after birth owing to the fact that the latter was suffering with general paralysis and was mentally unbalanced. A closer check-up of the familial history revealed that the mother had been in very poor health for several years and had been taken to the neurological hospital three weeks before the child was born. In view of her serious condition and a three-plus Wassermann reaction, she was inoculated with malaria despite the lateness of her pregnancy. Two weeks later, after six severe chills, she went into labor and a living child was born spontaneously. The blood from the umbilical vein gave a three-plus Wassermann. The mother's condition never improved, and she died a few months later. No signs of syphilis were ever observed in the child, who remained at the clinic up to the age of seven months, when he was discharged in good condition, but with the spleen still slightly enlarged. A subsequent examination at the age of a year revealed a healthy, active child, normal for its age, but still carrying a small splenic tumor. Provocative injections of adrenalin failed to demonstrate plasmodia. In this case the locality and the time of year made it possible to exclude any post-natal malarial infection, and there could be no slightest question that this was a case of congenital malaria due to intrauterine transmission of the plasmodia. The possibility of such transmission should always be borne in mind when a pregnant woman is to be inoculated with malaria.

A Preliminary Report of Twenty-Three Cases of Corneal Opacities Treated with Surgery and Radium.—H. L. Hilgartner and Henry L. Hilgartner, Jr., relate their experience with an operation described by Meyer Wiener in 1926-27 for the removal of corneal opacities, which was followed by remarkable improvement in every case. The procedure consists in making a crucial incision through the scar with a small sharp scalpel, the incision being extended almost to the margin of the cornea, both vertically and horizontally, and into the cornea as far as possible without penetrating the anterior chamber. The apex of one of the quadrants is then lifted up with a small sharp iris hook, and with the scalpel dissected back toward the base of the tri-

angle, care being taken to keep in the same corneal layer throughout the dissection. At the base of the triangle the segment is cut off from its attachment. The remaining segments are dissected in like manner. Atropine is instilled, a small quantity of xeroform powder dusted over the denuded area and a dry gauze dressing applied. The authors have observed under the slit lamp that the scar tissue is thinner following the operation, due to the fact that the corneal epithelium regenerates more rapidly than does scar tissue. In spite of the gratifying improvements following these operations, there was still much to be desired. Since Lane and others had reported favorably on the results obtained with radium in these cases, the authors started using this agent. The patients received weekly treatments of 10 mg. of radium element for two and one-half, three, and three and one-half minutes, respectively, passed to and fro from one to two millimeters above the cornea. Following the third application radium treatments of three, four, and five minutes were given every three weeks. As an anesthetic, 3 per cent cocaine was used and silver-plated lid retractors protected the lids and gave exposure. Scar tissue appears to be more sensitive than normal tissue and becomes markedly softened by erythema doses of radiation. If there is failure to get a clear spot the operation and radium treatment may be repeated. —*Southern Medical Journal*, July, 1931, xxiv, 7.

Amidopyrine and Water Economy.—A series of observations is reported by D. Scharf with reference to the influence exerted by amidopyrine upon the water economy of the body. He administered 2 gm. daily by mouth of amidopyrine, distributed in such a way that each patient received 100 c.c. of a 2 per cent aqueous solution in the course of the day in teaspoonful doses. In a few cases the same amount was administered in tablet or suppository form, likewise in fractional doses. The weight was accurately recorded each morning with the patient in a fasting condition. The tests were made chiefly on compensated and decompensated cardiac patients, but also on patients suffering with other conditions in which the circulation was not affected, who served as controls. The decompensated cardiacs were completely digitalized before the amidopyrine was administered, and care was taken to keep the circulatory conditions constant in these individuals by regular small doses of digitalis. Most of the tests were made on ordinary house diet after it was established that patients with a salt-free diet reacted in essentially the same way, only to a less degree. In 84 per cent of the patients treated for five days, with and without circulatory disturbances, there appeared a retention of water and of sodium chloride, accompanied by an increase of body weight in excess of kilo. No clear connection could be demonstrated between the degree of circulatory disturbance and the amount of water retention. After the amidopyrine was stopped the retained water and sodium chloride were excreted and the body weight decreased. During and after administration of amidopyrine the individual patients exhibited various peculiarities in the nature of the water retention. This was especially noticeable in the decompensated cardiac patients. Amidopyrine inhibits digitalis and purin diuresis; a short treatment with this substance also inhibits salyrgan diuresis in the majority of cases. Excretion of water is inhibited in greater degree than that of sodium chloride. It is impossible to say whether this is due to the action of amidopyrine upon the tissues directly or upon the central nervous system.—*Klinische Wochenschrift*, June 13, 1931.

The Significance of Raised Blood Pressure.—John Hay says that an abnormally high blood pressure indicates some underlying psychological or pathological abnormality. It is the result of several factors—frequency and vigor of the ventricular systole, the tension of the arteries, and varying peripheral resistance. The diastolic pressure is important, since it is increased by any cause which augments peripheral resistance. Hence vascular elasticity is likewise highly important. Hay thinks that in some instances there is faulty reading of the blood pressure. In a patient with a systolic pressure of 200, there may be a silent gap between 180 and 160, and unless this is recognized a blood pressure of 160 will be recorded. This mistake may be avoided by verifying the systolic pressure as judged by auscultation with that obtained by palpation of the radial pulse. To take the age plus 100 as the normal limit for blood pressure is incorrect. A table compiled by Hay, giving the average of a very large number of blood pressure records, shows, for example, for age 50, a systolic pressure of 130 and a diastolic pressure of 83; for age 60, 135 systolic and 85 diastolic. In assessing the significance of high blood pressure patients should be classified under three headings: (1) hypertension due to psychological influences; (2) hyperpiesia with no essential primary renal involvement, but with some degree of cardiac hypertrophy and arterial disease, and (3) a renal group. A steady diminution in the expectation of life accompanies high blood pressure, and this is more marked in the obese, and is most serious if it appears during the middle period of life. In the treatment, moderate exercise, suited to the individual, tends to lower the pressure slightly and proves of benefit. In the later stages more can be done by a revision of the patient's mode of life than by drugs prescribed for the purpose of lowering the blood pressure. When feasible it is well to prescribe bed rest

for a few weeks, and bromides. Worry and anxiety should be removed so far as possible. The diet should be carefully supervised, especially in those above normal weight, since every unnecessary pound of weight adds to the load the heart has to carry. A good rule as to food is "No second helping." A blue pill or calomel once a week, followed by saline, and saline daily is of undoubted benefit. Iodine is acceptable, either as collosol iodine or as the tincture. Within the last few years luminal, acetylcholine, and the sulphocyanates of potassium and sodium have come into prominence. They are more likely to be of service in the earlier than in the later stages. Luminal has a helpful sedative effect. The sulphocyanates are prescribed in doses of 1½ to 2 grains three times daily after food, the dose being increased gradually.—*British Medical Journal,* July 11, 1931, ii, 3679.

Studies in the Function of the Saliva.—Since there is theoretically a relationship between the function of the sweat and that of the saliva, Julius K. Mayr reports that after making intensive studies of the former he undertook parallel investigations of the saliva in the same individuals. He found wide variations in the hydrogen ion concentration during the course of a day. Normal saliva has an acid type of reaction, the pH ranging between 5.0 and 8.5. This wide range of difference permits the conclusion that there is a considerable variation in the composition of the saliva. These acid values are present not only as the average values among many individuals, but also as the average for a day's variation in one and the same individual. Just as occurs with the urine, the acidity of the saliva is greater soon after a mixed meal than it is a few hours later. In a general way the acidity or alkalinity followed the same curve as that of the urine and sweat, but the curves varied considerably in different individuals. For example, in patients suffering with psoriasis there is regularly a shift toward the alkaline side in the saliva. In diabetes, on the other hand, the shift is toward more strongly acid values. The more severe the diabetes, the greater the degree of acidity. Whenever the body is called upon to excrete large amounts of material, saliva as well as sweat is charged with some of this labor. If 15 gm. sodium bicarbonate were administered to a subject with normal kidneys, these organs took care of the entire amount, and the saliva showed no alkalinity. But if 30 gm. were administered, the saliva exhibited an alkalinity curve parallel to that of the urine. Tests made in 6 patients with disturbed renal function showed a delay in the curve of urinary alkalinity, which rose only gradually, while in the saliva the alkaline values rose immediately, and were maintained for 2 hours before they returned to the former level. Thus it is seen that the saliva is called on for the excretion of alkaline valences in a measure far beyond the limits of error, when a disturbance of renal function exists. This suggests the usefulness of a methodical examination of the saliva as a test of kidney function. The amount of urea found in the saliva was as a rule between 8 and 20 mg. per cent. Administration of 15 gm. urea to subjects with healthy nervous systems resulted in the finding of increased amounts of the substance in the saliva within an hour, which were maintained for another hour and then returned again to normal, thus furnishing one more proof that saliva participates in the work of excretion.—*Klinische Wochenschrift,* July 4, 1931.

Atropine Treatment in Encephalitis.—E. Schenck reports excellent results from use of atropine in a series of 10 cases of encephalitis. The favorable effect was first seen in the cessation of driveling, then of the fixed stare; then the power of motion returned to the lower extremities. After this a considerable period of time elapsed before the stiffness of the upper extremities yielded to the treatment. The amount of dosage required differed with different individuals. For most of the patients rather large doses were necessary, probably because of the chronicity of the cases. Schenck began with 3 drops of the usual one-half per cent solution, and increased the amount daily by 2 drops. Later on he administered the atropine in the form of tablets, a method that is very convenient and absolutely exact. No disturbances of the internal organs were noted. The pulse, originally high (often over 120) came down to 96. Anorexia and vomiting were quickly overcome; loss of weight was soon compensated, and was never great enough to be disquieting. In a few cases the patients even put on weight, without any special dietary measures. In one case there were severe cerebral symptoms of atropine intoxication, requiring injection of morphine. The patient refused further treatment, but 10 days later begged for it again. All these effects could be avoided if the atropine were given correctly, either maintaining the dosage reached or reducing it to a smaller amount that could be tolerated, then slowly increasing it again. Patients who have already received atropine are well pleased to take it again. Some are at first disconcerted by the disturbances of vision that it causes at the outset. Individuals vary in their susceptibility in this respect, some never speaking of these troubles, while others require reassurance. As a rule all are quite eager to take atropine when they perceive that they are getting back the use of their limbs. Not infrequently even patients of low intelligence and seeming psychic unresponsiveness demand to participate actively in the treatment. Five case histories are outlined as evidence of the value of the method.—*Münchener medizinische Wochenschrift,* July 10, 1931.

LEGAL

PHYSICIAN'S FEES—PATIENT'S ABILITY TO PAY

By LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

The physician is called upon to do an immense amount of charity work. Very often he is imposed upon by those who are financially able to pay. Few persons have any idea of the extent of the gratuitous contribution of physicians and surgeons to society. In an article published in the JOURNAL under date of March 15th, 1931, and entitled, "The Economic Contribution of Physicians to the Community," Dr. Charles Gordon Heyd, President-Elect of the Medical Society of the State of New York, says:

"It is claimed by competent statisticians that physicians treat one-eighth of the population of the United States free of charge. Since at all times there are two per cent of the population incapacitated and about four per cent physically impaired, it follows that from 375,000 to 500,000 persons are daily treated without charge."

The system which brings about this situation is economically unsound and, as Dr. Heyd properly points out:

"The doctor is entitled to a monetary return for his labor that is fair and commensurate with his services, training and experience."

With these preliminary observations, we will discuss a case recently decided by one of the courts of this country where the question was squarely presented as to whether the financial ability of the patient to pay should be taken into consideration in fixing the fair and reasonable value of the services of the physician, in an action brought by the physician to recover for medical services rendered.

Over a period of years the plaintiff in this case, who specialized in the treatment of goiter conditions, had treated one Mrs. McD and succeeded in improving her condition and had finally performed upon her a highly successful operation for the removal of a goiter. Her husband Mr. McD. died, and the doctor filed a claim against his estate for the sum of $15,000 for professional services. The executrix disallowed the claim in that sum, but offered the doctor $1,000 in settlement. The doctor refused to accept the smaller sum and sued the estate for the full amount. The matter came on for trial and the doctor obtained a judgment for the sum of $3,500.

An appeal was taken on behalf of the estate raising the question whether certain evidence was properly admitted by the court upon the trial which, if excluded, would have resulted in a failure of proof to sustain a verdict of more than $1,000. A portion of the testimony which was claimed objectionable was that of a physician and surgeon of some thirty-four years' experience in the community, and was in part as follows:

"Q. Are you familiar with the general practice of physicians and surgeons in this community and in this State with reference to the matter of fixing the amount of their bills considering the financial standing of the patient? A. I am.

"Q. What is that practice? A. I think it would be according to the financial standing of the patient, his annual income, a certain amount. A poor person would not pay as much, or anything at all.

"Q. What is the relation between the bill for a major operation and the yearly income? A. I would say about ten per cent of the annual income."

Then a hypothetical question was asked as to the reasonable amount of the plaintiff's compensation, describing his treatment of Mrs. McD. and stating the approximate wealth of Mr. and Mrs. McD. to be $1,600,000. To this the witness answered:

"A. I should think his fee of $15,000 would be just."

Another doctor of wide experience and practice was called and similarly testified as follows:

"Q. Are you familiar with the practice of physicians and surgeons in this community as to taking into consideration the financial standing of their patients in fixing the fee? A. I am familiar with it. It is based upon their income, the amount they earn per month or year.

"Q. Roughly speaking, what is the relation between the amount of the estate or the amount of the income and the fee for major operations? A. The practice varies somewhat. With some it is a practice of charging a month's income for major operations, again ten per cent of the total yearly income for major operations.

"Q. State how widespread that practice is. A. So far as I know it is universal in the United States.

"Q. And you are familiar with the general practice throughout the country in that respect? A. I am fairly so."

In response to a hypothetical question the same as put to the other doctor he testified:

"A. I would say a $15,000 fee is reasonable and proper."

The court affirmed the judgment and in the course of its opinion said:

"We are of the opinion that the rule best supported by reason, in any event as applicable to this case, is that in some substantial measure the reasonable compensation of the physician is determinable by the ability of the patient or her husband to pay for the service, since the contract for the service was by the physician directly with the patient, for the service to be rendered to the patient, the services including a major operation, and it being shown by competent evidence that it was customary among physicians to charge for such service in some measure according to the ability of the patient to pay for such service."

The ruling of this court, however, is not in accord with the rule in many States in this country. A number of State courts have, when presented with the problem of determining the value of professional services, treated such services as a commodity and rejected the financial ability of the patient to pay as an element in fixing the proper amount of the physician's fee.

For example, in Iowa, in an action brought by a physician for services rendered, the trial court charged the jury as follows:

"The facts of the circumstances of the parties subject to be charged as defendants herein do not constitute an element in fixing the value of the services. And, if any evidence has been offered on this subject, the jury should entirely disregard it as the right to recover an amount that might be recovered on the financial worth or standing of the defendant."

On appeal, that portion of the judge's charge already referred to was approved by the appellate court in the following language:

"The instruction is, we think, correct. There is no more reason why this charge should be enhanced on account of the ability of the defendants to pay, than that the merchant should charge them more for a yard of cloth or the druggist for filling a prescription, or a laborer for a day's work. It is true a physician in general practice will often be called upon to treat indigent persons from whom he will not be able to recover the value of his services. He may take this into account and regulate his charges with reference to that fact, just as a merchant may take into account probable bad debts in fixing his per centum of profit upon his goods. But the value of a service depends upon the difficulty of rendering it, and the skill required in its performance, and, sometimes, upon the results accomplished, and not upon the riches or the poverty of the person for whom the service is performed. If the ability to pay determines the reasonableness of a charge, then the richer a man is the more he should pay for any service. No such rule of charge can be recognized or countenanced by the law."

In Alabama, in a similar case the court, in holding that the financial ability of the patient to pay was not relevant testimony in the case, said:

"The trial court erred in admitting testimony as to the value of the patient's estate, against the objection of the defendant. The inquiry was as to the value of the professional services rendered by the plaintiff to the defendant's testator and, * * * the amount or value of the latter's estate could shed no legitimate light upon this issue nor aid in its elucidation. The cure or amelioration of disease is as important to a poor man as it is to a rich one, and * * * the services rendered the one are of the same value as the same services rendered to the other."

In Texas, in passing upon the point here involved, we read from the court's opinion:

"We are of the opinion, further, that the court erred in permitting plaintiff to show the reasonable value of his services by proof that defendant was wealthy, coupled with further proof of a custom among physicians to graduate their charges according to the financial condition of the patient, and to charge a wealthy person a higher fee by reason of his superior ability to pay. * * * Certainly no court would hold that the value of ordinary labor could be determined by such a test, and upon principle we can see no distinction between such a claim and one of the character now under discussion."

Every principle of equity and justice is in favor of the rule that the financial ability of the patient to pay should be a factor in determining the reasonable value of the services of the physician. In one case in the State of New York the court very properly followed this rule. The facts are interesting and may be briefly stated as follows:

A wealthy man presented himself at a hospital for care as a charity patient, and under a mistake as to his means he received such treatment. Upon his death it became known that he was worth at least $400,000, and two surgeons who treated him at the hospital made a claim against his estate to recover $2,000 as the reasonable value of their services. The court first held that they were entitled to receive such reasonable value and then, in determining the reasonable value, held that it was proper for the court to consider evidence as to the financial standing of the decedent. In its opinion awarding the doctors their claim of $2,000 in full, the court stated the following:

"In measuring the value of a lawyer's services, the prominence of his clients can be taken into account. An equal, and probably a greater, social bearing is attributed to medical service. In order that such skill may be highly developed and well paid, and that the greatest number and the

group itself served thereby, it is recognized as a social necessity that those who are quite able to pay, especially for the best, should pay adequately and liberally, in any case, to avoid the social danger incurred either in allowing those less able, or unable to pay, to go about the community in a diseased, untreated condition, or in allowing the skill and equipment of competent medical men to be lessened, or lost to the locality, by inadequate over-all recompense. ***

"From the social point of view, it is immaterial whether the wealthy recipient of medical service is, or is not, unconscious at the time the physician is called, or is in attendance. For the same reason, such a person obtaining such service in the manner in which this decedent did, is in no different position. Neither of them has any social right to expect such service from such men at the same rate, the inadequate rate, at which it is received by those who have less successfully made use of the opportunity that society affords, or who happen to be forced to avail themselves of the protection of the individual that accrues from the duty of the group to protect itself as a group."

The quotation above referred to leaves but little to be said on the point involved. It is refreshing to find a judge writing in this vein. The opinion is not only good common sense but in addition it does justice to the physician. Few people stop to think that the physician must pay his bills in precisely the same way as any other individual. His gratuitous contribution to society is enormous, and this in some measure should be compensated in determining the reasonable value of his services to patients of ample financial means.

CLAIMED IMPROPER TREATMENT OF FRACTURED ARM

A young man was brought to the defendant doctor for treatment with respect to a fracture received from a fall from apparatus in a gymnasium. The doctor was told that the patient's forearm was fractured and that temporary cardboard splints had been applied as a first-aid measure. Upon examination the doctor found the arm in a very bad condition and informed the patient that *x*-rays should be had as soon as possible, but as it was late at night they could not be obtained until the following day. The doctor then placed the man on a table and without an anaesthetic attempted to get the bones in their proper positions as well as possible, and then applied an anterior-posterior splint with a sling.

The next morning the patient went with the doctor to a hospital where *x*-rays were taken. These pictures showed a fracture of both bones of the lower forearm with considerable overriding and displacement, especially of the lower fragment of the radius. The doctor advised the patient that further manipulation was necessary and recommended an anaesthetic which was refused. With the aid of a fluoroscope the doctor attempted to correct the overriding without an anaesthetic but because of muscular spasm he had difficulty. A metal splint was applied but failed to hold. Then a short posterior and long anterior splint was used. The doctor explained that the nature of the fracture was such that it was altogether likely that a good result could only be obtained by an open operation but this was promptly refused.

The young man returned to the doctor several times for treatment. About three weeks later additional *x*-rays showed some displacement of the fragments. The doctor again advised an open operation, but it was again refused. When last seen by the doctor there was pronation and supination, no false point of motion or crepitus and the fragments were in fair position. The man was to return but failed to do so. In the whole course of treatment the patient was uncooperative, and failed to comply with the doctor's request that he obtain additional *x*-rays.

The next the doctor heard of the case was a communication some time later from another doctor that the patient had consulted him, and he had found a displacement of the fragments of both the radius and the ulna and non-union. The said doctor performed an open operation which gave the man a good end result.

An action was instituted against the defendant doctor charging malpractice. The case was duly tried before a judge and jury and a verdict rendered in favor of the defendant.

NEWS NOTES

POLIOMYELITIS AND THE SCHOOLS IN NASSAU COUNTY

The Medical Society of Nassau County has advised that opening of schools be not postponed on account of poliomyelitis, and is allaying public apprehension and making school attendance safe by particular instruction to teachers and school nurses in discovering early signs of illness among the students.

A conference of medical men and school authorities was held on August 31 to which were invited Ambrose J. Fry and Wellington Mepham, school district superintendents of Nassau County, the school superintendents of the two largest villages in each of the three townships, the health officers of the three townships, Drs. William H. Runcie, Hempstead; Charles A. Steuer, North Hempstead; and Walter F. Stillger, Oyster Bay; and Dr. M. D. Dickinson, District Health Officer for the State Department of Health. Following this conference, the Executive Committee of the Nassau County Medical Society conferred and issued the following statement to the school authorities and to the press:

"The Executive Committee of the Medical Society of the County of Nassau has given a great deal of study to the subject of infantile paralysis and the opening of schools. We have consulted with experts and we have held a conference of school executives and health officers. After careful consideration of all the known facts and factors we are of the following opinion:

1. There has been no sharp increase in the number of cases during the last three or four weeks, and the total number of cases reported are not sufficient to constitute an alarming epidemic.

2. While it is generally believed that the disease is transmitted by contact, there is nothing to indicate that it is more dangerous to associate with children than with adults.

3. Unless a child is being kept closely confined to his own premises and away from church, places of entertainment, and his customary neighborhood playmates, he would be in no greater danger in school than he is at present.

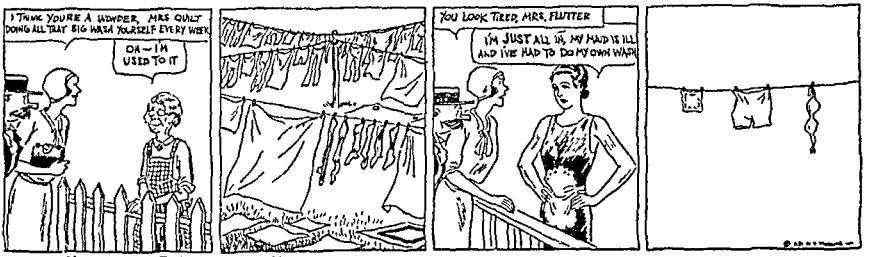
4. When in school the child will be under the daily direct supervision of his teacher, school nurse, and the school physician who will be particularly instructed in the early recognition of dangerous signs and symptoms. Early recognition of the disease is our only hope of preventing crippling. With the double supervision of parent and school, the child is doubly guarded.

5. To assure this the Medical Society will hold a meeting on September 8th for school doctors, nurses, and others interested, and will secure as a speaker a poliomyelitis expert who will lay particular stress on early recognition and precautions to be observed in schools.

6. In view of these facts it is our carefully considered opinion that we are not justified in recommending that the schools be kept closed. Final decision will rest with the school authorities of each community. This statement is issued merely because our advice has been asked."

The County Society will next sponsor a meeting in the Auditorium of the County Police Headquarters Building in Mineola, Tuesday evening, September 8, of superintendents of schools, and medical inspectors of schools. The school authorities have been asked to direct their school nurses to attend, and to invite any school teachers who are interested. Dr. George Draper has been secured to instruct those present in the school aspects of poliomyelitis. This meeting will be well reported to the daily press in articles reassuring parents and children of safety in attending school and combatting the feeling of uneasiness which many parents have expressed.

The meeting will be followed up by the mailing of four thousand letters, distributed through school authorities to teachers, quoting the nine diagnostic points from the Journal of the Medical Society of the State of New York (See August 15 Journal, page 1038) and asking them in turn to hold meetings with the school inspectors.



A semi-popular meeting was held in the police headquarters on the evening of September 8, and was attended by 250 persons including health officers, school nurses, members of boards of education, school teachers and others interested in poliomyelitis. Dr. J. W. Bulmer of Glen Cove, vice president of the Nassau County Medical Society, presided. Dr. George Draper of New York City explained the nature of poliomyelitis and methods of its recognition and control. Dr. Wm. A. Howe, Medical Director of Schools of the State Department of Education, reassured the people regarding the relation of the schools to the spreading of poliomyelitis.

The meeting adjourned without taking any definite action. The opening of the schools in Nassau County is generally deferred as was done in New York City.

THE DAILY PRESS

Mr. and Mrs.—

A Big Monday's Wash—Ancient and Modern

From the N. Y. *Herald Tribune* *August* 31, 1931

SANITARY ODORS

If foul smells suggest sickening conditions, why may not pleasant odors create a healthful atmosphere? The New York *Times* of August 13 comments editorially on the possibilities of a new device for spreading attractive perfumes out of doors, and says:

"The latest device is to bring to town the fragrance of a rose garden, a field of new-mown hay or a honeysuckle bower. The new machine can spread synthetic scent over vast areas—swamps, refuse dumps, stagnant pools, glue factories and other regions where the natural atmosphere is far from pleasing, declares the editor of *Aromatics Magazine*. The new machine is described in a Paris dispatch as 'a cross between a motor-spirit pump and a vacuum cleaner.'

"On an island in Lake Daumesnil, within the boundaries of the French Colonial Exposition, a luxurious restaurant is enjoying a successful season. Its romantic setting is made deliciously fragrant by perfuming the surrounding lake. Guests arriving by motor drive over wide bridges above the perfumed waters.

"Various happy applications suggest themselves. Certain residents of Long Island might be glad to have a screen of jasmine laid down on the open dump of Queensboro Hill. Unpleasant exhaust gases on Broadway and Fifth Avenue might be masked under gusts of Parma violet. And it should be simple to flood the subways on hot days with the scent of sweet clover."

TUBERCULOSIS IN PIGS AND HENS

It is not popularly known that tuberculosis often affects pigs and hens as well as cows; and that a great factor in the disease is the custom of throwing the offal from the dressed animals back into the pens and yards of the live animals, thus inviting the direct spread of disease. The New York *Sun of* July 27, commenting on the disease, says:

"Having achieved considerable success in the campaign to free cattle from tuberculosis, the practicability of which is now not disputed, Federal and State agricultural department officers have now undertaken to demonstrate that poultry may also be rid of the disease. Their work will be carried on principally in the Mid-Western and North Central States, where fowl tuberculosis causes serious losses. Swine raisers are also interested, for, through close association with hens, the pigs become infected. The diseased poultry and swine impose heavy losses on the growers.

"The campaign for tuberculosis-free flocks of hens will be carried on as the campaign for tuberculosis-free herds has been conducted. The poultrymen will be instructed in the prevention of infection and informed as to the folly of tolerating in the chicken runs a malady that keeps dollars out of their bank deposits."

SURVIVAL OF THE WEAK

Articles frequently appear in the current press on the subject of "who shall inherit the earth." The articles recite the complete disappearance of the enormous fish and reptiles of by-gone ages, and the threatened extinction of our wild mammals which have more bulk than brains. But the writers seem to follow the style of assigning the survival to insects—and there are many arguments to support the theory. The subject is treated in verse and rhythms by James J. Montague who writes in the New York *Herald Tribune* of August 21, as follows:

"The flies careen about the house
With undulating rhythm,
And, like the wicked rat and mouse,
They bring diseases with 'em.
They are not large, they are not rough,
They are not fierce or savage,
And yet we watch them do their stuff
And calmly let them ravage.

"We know, as we have known for years,
That when, in hut or palace,
A germ-encrusted fly appears
His heart is filled with malice.
We know each time we hear him sing
His predatory carol,
The evil, ugly, buzzing thing
May put our lives in peril.

"But though we've dwelt upon this earth
Through many, many ages,
The fly, which has no grace or worth,
In murder still engages.
He's flown around the whirling sphere
In this or that direction,
And day by day and year by year
Has spread about infection.

"The tiger lurks in his retreat;
The lordly lion cowers;
Both know that it is not discreet
To brave man's mighty powers.
The polar bear is hidden out
On icebergs bleak and jagged,
And yet the fly still swarms about
And runs us humans ragged."

AMERICAN NURSES' ASSOCIATION

The *New York Times* of September 2 comments editorially on the American Nurses' Association as follows:

"One evidence of the general interest of the nurses in their profession is the formation of a committee to survey nursing education and economics. By voluntary contribution a fund of more than $90,000 was accumulated. It is being used to find out if there are enough nurses being graduated to care for the sick, if specilization is better than general care, what are the chances of continuous employment in the private field and many other matters of importance. Some of these questions have already found an answer. More nurses are needed for mental and contagious disease work. Emphasis which has for years properly been on "quantity production" should now be shifted to quality. For a time there were not enough trained nurses. Now there are enough, though almost none of them have continuous, year-round work. Even in 1928, their most prosperous year, the average private-duty nurse was employed only eight months of the twelve. People in moderate circumstances will be glad to know that the nurses are at work on the problem of giving them service at a price they can afford to pay."

READING FOR INSOMNIA

The *New York Sun* of September 2 comments unfavorably on the list of books suggested by Dean Inge of St. Paul's Cathedral, London, to be read at bed time for the purpose of producing sleep. The *Sun's* editorial writer says:

"Few readers, whether wakeful or not, would willingly pick up 'Society in Rome Under the Cæsars,' 'Christian Mysticism,' 'Speculum Animæ,' 'Types of Christian Saintliness,' 'The Philosophy of Plotinus' or 'The Eton Latin Grammar,' which are the books mentioned by the Dean. Surcease from insomnia comes from the pages of a book which is just on the shadowy line that divides the readable from the unreadable, not from a book that will drive the ordinary reader away by its opening paragraph. The books mentioned by the Dean would be laid aside instantly by the insomniac and the sufferer would be roused to an even more intolerable alertness. It is a book which stupefies and lulls the senses that is needed, a book that contains paragraphs that can be read over two or three times without convincing the reader that he has read them a single time, a book that fails, by the scantiest margin, to hold the interest. Every reader must compile his own list. No general prescription will do."

BOOK REVIEWS

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them A selection from this column will be made for review, as dictated by their merits or in the interests of our readers

THE SIGNIFICANCE OF WATERBORNE TYPHOID FEVER OUTBREAKS, 1920-1930 By ABEL WOLMAN and ARTHUR E. GORMAN Octavo of 82 pages Baltimore The Williams & Wilkins Company, 1931 Cloth, $2 00

This small monograph is an important contribution to the study of waterborne typhoid fever The authors have collected, assembled and interpreted the results of investigations of waterborne typhoid fever outbreaks in the past ten-year period While a detailed bibliography is not given, the amount of time required for the study made must have been considerable

The interpretation of the facts and the conclusions drawn seem very well taken They are moreover most interesting and timely in the warning they convey as to the alarming incidence of waterborne typhoid particularly in the small municipality, where evidently the administrative control over the collection, treatment, storage and distribution of the public water supply is inadequate A startling fact brought out is that unprotected cross connections between polluted fire or auxiliary water supplies and public water systems stand out as the most important single source of these outbreaks The financial and personal liability resulting from such outbreaks should show municipalities and private water companies the necessity of more strict control In the introduction Dr Thomas Parran, Jr, emphasizes the facts brought out by this study and calls the attention of public health and waterworks officials to the negligence which permits such epidemics to occur

JOSEPH C REGAN

ABDOMINAL PAIN By JOHN MORLEY, Ch M, F R C S Octavo of 191 pages, illustrated New York, William Wood & Company 1931 Cloth, $3 50

A noted surgeon has recorded his observations on abdominal pain and in so doing has created an entirely new and fruitful conception of its interpretation

The viscero-sensory and viscero motor reflexes of Mackenzie so widely taught to medical students the world over are critically reviewed and found wanting The author considers to have demonstrated, and rightly so in the opinion of the reviewer, that a viscero sensory reflex does not exist and that it is a peritoneo-cutaneous or peritoneo muscular transposition of sensory stimuli with which we are dealing in most instances of abdominal pain The existence of a true visceral pain, which has been denied by other investigators is considered as established by the author of this remarkable little volume It furnishes delightful, instructive and constructive reading for every student of medicine, graduate or otherwise

GEO WEBB

MEDICINE A Historical Outline. By M G SEELIG M D Second edition 12mo of 205 pages illustrated Baltimore, Williams & Wilkins Co, 1931 Cloth, $3 00

The demand for a second edition is evidence of the place this work has attained as a brief manual among the histories of medicine It has been the purpose of the author to give a panoramic view of the development of medical science intended more especially to stimulate interest on the part of students We feel that he has accomplished his end admirably

The book consists of eight lectures comprising a course given by Dr Seelig to the students of the St. Louis University School of Medicine The material is arranged in chronological order beginning with the primitive period and concluding with the 19th century and covers remarkably well the salient facts in the evolution of medicine The text is written in attractive form that holds the attention of the reader Added interest and value is afforded by the considerable number of portrait plates of outstanding characters which embellish the reading matter

In this second edition the author has taken the opportunity to correct errors that crept into the first edition The book makes its appeal not only to medical students but to physicians and others seeking a delightfully interesting account of the story of medicine We heartily recommend it as one of the best handbooks among recent medical histories

C F

THE SEX FACTOR IN MARRIAGE A book for those who are or are about to be married By HELENA WRIGHT, M B, B S 12mo of 122 pages New York, The Vanguard Press, 1931 Cloth, $2 00

Dr Helena Wright, a London physician, has written a strange and intensely fascinating book on the sex factor in marriage She takes it for granted that one of the prime requisites for a happily wedded life is intimate sexual understanding She is convinced that much of the marital unhappiness and divorces must be traced to dissatisfying and improperly performed sexual intercourse and maintains that most of these cases are dismissed by the physician with such a cursory diagnosis as dyspareunia or sexual neurosis or sexual incompatibility Just as healthful dieting in a civilized person depends on an intelligent choice of foods and a conscious control of one's appetite, so should satisfying sex relationship be subject not to one's uncontrollable instincts but to an intelligent familiarity with the sex act

The facts cited in this book never form part of a medical school curriculum, and even though some physicians may object to the nature of such a treatise it would be advisable for the practitioner to be informed of its contents The information seems superficially sensual, but reflects a praiseworthy courage on the part of the writer to record some of the facts of civilized existence and to interpret them for us

Dr Wright adopts a more intimate relationship with her reader than the physician does with his patient For that reason alone it is a creditable undertaking Our present attitude on love and marriage and divorce is apparently inspired and influenced by our religious affiliations And because this book bears an endorsement by members of the English clergy the American Y M C A, and is accepted by the U S Customs Service, the reviewer can speak freely without fear of bigoted criticism There is but one justifiable objection to this book—it will no doubt readily find its way to sexually gullible youngsters, but proper legal regulation of its sale to properly qualified persons should help to solve this problem

This book should serve to modify our Puritanical conception of morals for by its whole hearted frankness it should serve to simplify human relationships It should be read by all newly married couples who wish to be introduced to the physical intimacies of a happy and successful married life

EMANUEL KRIMSKY

OUR NEIGHBORS

RURAL MEDICAL SERVICE IN VERMONT

The *New England Journal of Medicine,* of July second, says:

"According to Dr. W. G. Ricker of St. Johnsburg, secretary of the Vermont State Medical Society, there are now 110 towns and villages in Vermont without the services of a doctor. This statement was contained in a report on medical facilities for rural people which he made on June 17 in connection with the general session of the Vermont commission on country life.

"Figures contained in his report showed that 40 years ago there were 693 physicians in the state, and hardly a hamlet was without one. Today there are 458 doctors, 34 per cent of whom are in cities, and additional 33 per cent in towns of more than 2,500. There are 43 towns ranging from 500 to 1,000 in population without doctors, and also 67 towns with smaller populations which are in a similar position."

DISTRIBUTION OF DOCTORS IN MAINE

The August number of the *Maine Medical Journal* contains the following report of Dr. H. C. Knowlton, Chairman of the Public Relations Committee of the Maine Medical Association, on the distribution of doctors:

"We have heard considerable talk lately to the effect that our country districts are not getting adequate medical attention. It is to find if there be any truth in this talk that I have prepared a map of Maine, showing the location of the physicians and their relation to the population.

"Maine has an area of 29,895 square miles, but in this area there are only 490 cities, towns and plantations which have a population of 100 or more people.

"To serve this area there are 882 physicians. These men are located in 208 cities and towns. This leaves 282 towns of 100 or more population with no resident physician. However, the arrangement is such that only a very small part of the people in the state are beyond reasonable distance from a doctor.

"We are often told of the good old days when the town had four doctors instead of one and fees were much lower. I always feel that in those good old days four physicians were needed in that town. They made their calls either on foot or behind horses, where the maximum rate of speed was ten miles an hour, and over roads often hardly more than passable in the summer, blocked in the winter, and slippery quagmires in the spring and fall.

"I believe that the solution of many of our rural medical problems lies not in more physicians—God knows they are poorly enough paid as it is—but in better summer roads and winter roads opened for the automobile.

"I have arbitrarily taken an area ten miles in radius as that to be possibly served by each doctor or group of doctors. When one comes to plot the state in this manner one finds that in the majority of cases the circles overlap and the bulk of the population is within five miles of a physician. This is so in Androscoggin, Cumberland, Kennebec, Knox, Lincoln, Sagadahoc, Waldo and York counties. In Aroostook 2.5 per cent (2,000) are more than ten miles from a physician. In Franklin 5 per cent (1,000), Hancock 2.6 per cent (900), Oxford 4 per cent (1,281), Penobscot, 1.7 per cent (1,596), Piscataquis 3.5 per cent (650), Somerset 4 per cent (1,381), Washington 4.4 per cent (1,683) are outside the circle. These people are scattered in regions, many so isolated as to be out of the question so far as this survey in concerned. A circuit riding physician with an aeroplane would be their only solution. There are a few localities where physicians might settle with reasonable hopes of a living.

"I believe our hospital facilities to be adequate. I also believe that any physician capable of doing his own work can interest a nurse and citizens of his locality in founding a small institution. There are many such in the state.

"Our large hospitals are well run and altogether adequate. The severest criticism that can be leveled against them and their staff is that they do not pay the attention they should to the practitioners who send them cases.

"We are favored by having with us some 77 osteopaths, 70 chiropractors and 18 assorted healers. It is not my purpose to discuss the inadequacies of their methods of healing. They do not, however, relieve our problems in any way, as there are only 2 osteopaths and 6 chiropractors settled in towns of less than 2,500 population, and it is with these that we are chiefly concerned.

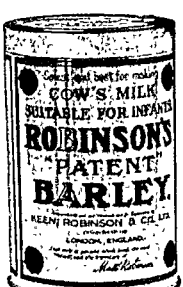
(*Continued on page* 1180—*Adv. xiv*)

..and in cases of

Infantile Gastro-Enteritis

FOR over three generations physicians have prescribed Robinson's "Patent" Barley as a valuable modifier in the diet of healthy infants. But its use has been extended to meet many *abnormal* conditions, such as those caused by Summer Diarrhea in infants.

The evidence collected by many authorities leaves little doubt that this trouble is often initiated by bacterial contamination of cow's milk.



Injudicious feeding, too, particularly failure to give sufficient water, is now widely conceded to be a contributing factor.

Another aspect of the ailment...the Dehydration Theory...attributes the aggravation of Summer Diarrhea to excessive perspiration of the infant, with consequent thirstiness and fretfulness.

If at this stage the mother makes the mistake of giving the infant milk, overfeeding may aggravate the condition.

• • •

IN THE TREATMENT of Summer Diarrhea, Robinson's "Patent" Barley is valuable as a drink to replace milk, not only because it supplies the necessary liquids without overfeeding, but because its colloidal, non-irritating nature gives it valuable demulcent properties.

ROBINSON'S "*PATENT*" BARLEY *is prepared in a strictly hygienic factory from the finest barley—dehusked and ground into a fine flour. Tested for quality. In sealed metal containers.*

THE DOCTOR
THE NURSE
THE PATIENT

NO ONE is immune to perspiration and the discomforts and social implication that go with it, for perspiration often leaves in its wake an odor quite unpleasant.

Here is an opportunity for cooperation between the doctor, who prescribes the remedy, the nurse, who applies it, and the patient who may need it. The remedy is simple enough and safe.

NONSPI

(AN ANTISEPTIC LIQUID)

checks the perspiration and prevents the odor, too. It needs to be applied only once or twice a week under the arms and to those parts of the body not exposed to adequate ventilation. Trial supply gladly sent to physicians.

YES, I'd like to try NONSPI. Please send me a free trial supply.

Name .....

Address ..... *City*..... *State*.....

THE NONSPI COMPANY, 117 West 18th Street, New York City

(*Continued from page* 1178)

The 18 assorted Christian Science, Naturopaths, etc., are all in cities. These people have seen the light and located in our centers of population, which are already well supplied with physicians.

"The smaller towns have 43 per cent of our population and there are 35 per cent of our physicians settled in these places.

"One fact stands out, which is to be put on the debit side of our ledger. Twenty-eight per cent of all our physicians are sixty years of age or over. That seems a large percentage and makes one feel that we are not getting our share of young men. Also while that 28 per cent applies to all our physicians, when we come to the smaller places, we find that 36 per cent of their medical staff are of mature age. This is a large percentage and augurs badly for the future. We do not want graduates from Class B. schools. Our people are as deserving of good treatment as any, but we shall need young men for the future.

"I believe that the survey should be carried on by the Association, the physicians indexed so the society can be always in close touch with conditions in the State. Thus can we more quickly fill our vacancies and give sensible advice when called upon."

CRIPPLES IN ILLINOIS

Figures on the extent and nature of the defects of cripples in Illinois are contained in an article in the *Illinois Medical Journal* of August. The number of known cripples is shown in the following table:

"Infantile paralysis	2,308
Spastic paralysis	1,062
Bone infection	907
Tuberculosis of spine	650
Accidents	555
Congenital deformity (unspecified)	497
Congenital deformity of joints	468
Club foot	418
Bow legs from rickets	386
Flat feet	268
Arthritis	197
Total these causes	7,716
Miscellaneous	2,295
Total	10,011"

Discussing the causes of the conditions, the *Journal* continues:

"The very large part played by infectious diseases in the production of the physically handicapped gives to this problem an important public health feature. Infantile paralysis alone is credited with responsibility for 23 per cent of all the physically handicapped child population. To no other single cause is attributed more than 7 per cent of the crippling conditions recorded. Spastic paralysis and bone infections were credited with

(*Continued on page* 1181—*Adv. xv.*)

(*Continued from page* 1180—*Adv. xiv.*)

10 and 9 per cent respectively, but these two are groups of causes.

"Since 1916 infantile paralysis has been charged with 1,033 deaths in Illinois. Thus it appears that 3 out of each 4 cases of this disease prove either fatal or physically disabling to the victims. This consideration suggests the importance of utilizing to the utmost the facilities for preventing and treating the disease. To this end the State Department of Public Health has collected and offers free to physicians convalescent serum. Early treatment with this serum prevents the onset of paralysis in a high percentage of cases and reduces the mortality to a minimum, according to reports on experimental observations.

"Tuberculosis of the spine was given as the cause of deformity in 650 cases. Prevention of this condition depends to a considerable degree upon the eradication of bovine tuberculosis and upon the pasteurization of milk.

"Malnutrition was charged with the responsibility of 386 cases of physical impairment that were reported as handicapped. Club feet were found in 418 children. Preventing malnutrition is simply a matter of reasonably good infant and child care. Where active disease plays no pronounced part the proper balancing of the diet together with a reasonable amount of sunshine keeps nutritional difficulties from arising.

"Club foot can nearly always be corrected satisfactorily by surgical measures. Many cases have been so skillfully managed that nothing short of a most careful examination would disclose evidence of the former condition.

"There are available preventive and corrective facilities which, if fully applied, would cut down the future handicapped population and reduce tremendously the impairment of those now suffering."

COSTS OF IOWA STATE SOCIETY

The August issue of the *Journal of the Iowa State Medical Society* contains a full page diagram of the proportional costs of the several activities of the Society varying from one per cent for medical economics to 27.5 per cent for the Journal. The occasion for the explanatory chart is set forth in an editorial, as follows:

"At the meeting of the House of Delegates during the last annual session the Trustees reported a deficit in the finances of the society amounting to $5,081.85 and recommended an increase in membership dues to remedy the condition.

"In an earlier editorial we have attempted to describe the many activities and worthwhile achievements of the State Society; and in this editorial we shall show the exact expenditures during the past year on account of these various activities and accomplishments.

(*Continued on page* 1182—*Adv. xvi*)

No modification necessary . . .

It is not necessary to further modify S.M.A. for normal full term infants, for the same reason that it is not necessary to modify breast milk - for S.M.A. contains the essential food elements in proper balance. Because of this close resemblance to breast milk, the very young infant can tolerate the fat as well as the other essential constituents of S.M.A. and it is possible to give it in the same strength to normal infants from birth to twelve months of age.

As the infant grows older, therefore, it is only necessary to increase the total amount of S.M.A. diluted according to directions.

Orange juice, of course, should be given the infant fed on S.M.A. just as it is the present practice to give it to breast fed infants, to supply an adequate amount of the anti-scorbutic vitamin "C".

(*Continued from page* 1181—*Adv. xv*)

"Attention is directed to the fact that the item of major expense are respectively, the publication of the Journal, the salaries of the necessary office personnel, the expenses incurred by the activities of the Legislative Committee, the costs of the studies of the Committee on Medical Education and Hospitals, the Speakers' Bureau, and the Annual Session. These six items are responsible for over 75 per cent of all costs for the year.

"Comparing the quality of our Journal and its costs with that of other state publications of a similar character, we are fortunate in our publication contracts. It is to be borne in mind further that the Journal is essentially maintained by paid advertising and that the annual cost to each member is less than one dollar.

"To discuss salaries and the amount of personnel necessary for the conduct of society affairs involves an unending delineation of the activities of the central office. Those in a position to understand all of the varied calls made upon the central office feel that the personnel has been maintained at a minimum level and that any further curtailment of help would cripple materially the effectiveness of this organization. The largest single salary paid is that given to the managing director, an office created and continued during the past three years by the will of the House of Delegates.

"Specific attention will not be directed article to the activities of the Legislative mittee and its accomplishments in the last lature since these matters will be discusse later article. It should be pointed out, ho that this expense should properly be divi half, since it is a biennial expense which be charged in two consecutive years. I one-half of the expense for legislative ac were charged to the year 1930-31, the cost would be $1,438, or 3.9 percent of the

"The amount required for the activities Committee on Medical Education and Ho is an unusual one and barring the develo of some unforeseen exigency, will not quired again for many years.

"The Speakers' Bureau, like the Jour purely educational in motive and essentiall supporting in its operations. If perpetuate Bureau may become an item of greater ex since the present plan of financing its act may prove inadequate. That it fills a de demand for scientific education is testified by the enthusiasm with which its services have been received and the increasing demand for speakers and courses of instruction. Certainly its support is in keeping with the recommendations of the Amercan Medical Association and the practice of other state societies.

(*Continued on page* 1183—*Adv. xvii*)

(*Continued from page 1182—Adv. xvi*)

"No comment is required relative to the expense of the Annual Session. Each member in attendance at any recent session appreciates the value of this conference and the necessity for expense in its operation.

"Particular attention is directed to the item of Administration Travel shown in the accompanying chart, since this expenditure has been questioned in several quarters. This item of $456 or .2 per cent of the total expense, covers actual mileage and hotel expense incurred by the executive officers of the society in transacting the affairs of their respective offices Needless to say this sum covers but a small part of the actual money spent by these officers in the performance of their duties and makes no provision for loss which they have cheerfully borne.

"The issue, if one exists, is not one of expense, but one of purpose. If economy exists in the management of our affairs, as our survey indicates, and a reduction of costs is demanded, then the House of Delegates, representing the members of our great society, must determine a reduced program of service and order their officers and committees accordingly. It becomes a question of progression or regression—a matter of society policy."

DROUGHT RELIEF HEALTH WORK IN TEXAS

The August issue of the *Texas State Journal of Medicine* carries the following item regarding the State Department of Health of Texas:

"STATE HEALTH DEPARTMENT ACTIVITIES: *The Dallas News,* of June 9, briefly but graphically described the work carried on in Texas by the State Department of Health during recent months. It quotes Dr. J. C. Anderson as proclaiming it the 'largest and most successful adventure in rural public health work ever conducted in a Southern State. . . .' and it says that an even broader program of work is contemplated. 'Details of the campaign in Northeast, Northwest, Central and Central Southwest Texas have been compiled in a bulletin, styled A Progress Report of the Texas Drought Relief Health Work, and distributed by the State Health Department.

"'The work has been carried out with funds supplied from the $2,000,000 appropriation made by Congress for emergency sanitation work in drought areas designated by the United States Department of Agriculture. The Texas Health Department was allotted about $25,000 for use during April and May and the report discloses that $33,500 was spent. In addition to labora-

tory work, there were in the field an epidemiologist, a mobile unit, a corps of nurses, engineers and inspectors.

" 'Central county committees were organized in more than fifty counties and particular work was done in improving milk supplies, water supplies, and in sewage disposal, as well as in the distribution of biologics for immunization against communicable diseases, including smallpox, typhoid and diphtheria. Requests for biologics were more than three times the estimated demand.

" 'Central committees were set up in sixty-five counties.

" 'County judges, county health officers and county superintendents are directing the work in most instances.

" 'Now that the work is well organized a new budget will be submitted to the United States Public Health Service before July 1, to cover twelve months, and the budget will be based on surveys and recommendations of county health officers and county judges.' "

GOLD MEDAL MEMBERS IN MAINE

The *Maine Medical Journal* for July has the following editorial on the recognition of those members who have practiced medicine for fifty years:

"A pleasing and unusual feature of this session was the presence of twelve of the twenty-eight living veterans in medicine, men who have practiced fifty years, and the presentation to them at the banquet by Governor Gardiner of gold medals commemorating their long and faithful service.

"In presenting these tokens, Governor Gardiner said:

" 'Perhaps it is the bustle of modern life that has brought more forcibly to our minds, the minds of the general public, the reliance that we must place in the medical profession. We have, in the ordinary course of life, come to recognize good health as associated with efficiency, and more and more people are turning to the medical profession, not only for the relief and cure of acquired ills, but for advice and treatment that will ensure good health as a matter of efficiency. Today a doctor has more responsibility than merely meeting the individual responsibilities that come to him as a member of the profession, and now owes it to the profession to assist his associates in shouldering the responsibilities that fall upon the medical fraternity to lead our citizens into paths of health and happiness. Your medical associations, national, state and local, have well-defined responsibilities toward their fellow human beings.

" 'Tonight the Maine Medical Association takes a very distinctive step in honoring those of your association who have spent fifty years or more in the practice of your profession. You speak in

If There Were No Pain

If pain and acute distress would not set off the protective alarm, there would be no need for prompt neutralization of gastric hyperacidity. As things are, the alarm must be heeded quickly. CAL-BIS-MA quickly neutralizes the excessive acidity that gives pain and distress, whether it is due to improper digestive function or excessive secretory activity. It raises no deceptive smoke screen by introducing digestive ferments. Neither does Cal-Bis-Ma bring new discomfort by excessive gas formation, and endanger the situation when gastric ulcer is present by distending the stomach. Sodium and magnesium for quick neutralization, calcium and bismuth for lasting effect and for protection of the mucous membrane, *colloidal kaolin* for the adsorption of gases and toxic substances.

In Gastric Hyperacidity

this memorial token, not only as members of your profession, but also for the citizens of three generations who owe a great deal to the ministrations of these gentlemen.'"

The New Hampshire Medical Society presents a gold medal to those who have been members of the State Society for fifty years, and lists two who are entitled to the honor. The Society also publicly recognizes the doctors who have been in practice fifty years and lists five who will receive the congratulations of the Society. (See the *New England Journal of Medicine,* June 4, page 1208.)

EXPANDING THE COLORADO JOURNAL

Plans are frequently announced for the union of the medical societies of several States in publishing a common medical journal. California, for example, joins Utah and Nevada in publishing *California and Western Medicine;* Oregon, Washington, Idaho and Montana join in publishing *Northwest Medicine,* and Louisiana and Mississippi join in the *New Orleans Medical Journal.* On the other hand, Delaware gave up its union with Pennsylvania and now publishes its own journal; and the *New England Medical Journal* was unable to persuade Maine and Rhode Island to give up their journals and join the other four States in supporting a common journal for all of New England.

The latest proposal for a merger of State medical journals is that of Colorado, that the Rocky Mountain States unite in publishing a single medical journal to be known as the *Rocky Mountain Medical Journal.* The August issue of *Colorado Medicine* announces the plan as follows:

"Former editors of *Colorado Medicine* and members of the Publication Committee have led in cultivation of an idea, a dream, of a *Rocky Mountain Medical Journal* to succeed *Colorado Medicine.* This idea took definite root last September when the House of Delegates gave authority to invite neighboring States of the Rocky Mountain chain to join with Colorado and Wyoming in such an endeavor. Authority also was given to change the name of *Colorado Medicine.*

"Formal invitations have now been extended to New Mexico and Montana at their respective annual sessions on behalf of the Colorado State Medical Society. The Wyoming State Medical Society has added her own invitation and has graciously stated to our neighbors that she is thoroughly pleased with the results of having joined with us some five years ago.

"As is natural, neither the New Mexico nor the Montana society felt in a position to take definite action at their meetings this summer.

"In the first place, New Mexico at present is

Collosol KAOLIN

CROOKES

COLLOSOL KAOLIN is a colloidal, neutral, non-irritating powder, insoluble in water, non-poisonous and passes through the intestinal tract unabsorbed.

The efficacy of Kaolin in the treatment of intestinal toxaemia associated with diarrhoea, depends in large part on its property of adsorbing bacterial toxins and preventing their entrance into the general circulation.

The adsorptive capacity of Kaolin for bacterial toxins is, however, directly proportional to the surface area of its particles; hence Kaolin of special structural state "porosity" and in the very finest state of sub-division "colloidal" greatly enhances the efficacy of the treatment

COLLOSOL KAOLIN adsorbs bacterial and allied toxic factors in the intestines and is a potent and efficient agent in rendering the poisons innocuous

COLLOSOL KAOLIN is of especial value in enteritis, colitis and bacillary dysentery. It soothes the mucous membranes and has a maximum covering power.

DOSE—From one half to two tablespoonfuls by mouth or by colonic irrigation.
Supplied in 6 oz. and 1 lb. cans

associated with another journal, an association which she would probably wish to sever or alter if she should adopt the Rocky Mountain plan. Her present association is with *Southwestern Medicine,* published at Phoenix for the States of Arizona and New Mexico and the western counties of Texas centered in El Paso."

"Montana's situation is different, but no less complex. At present she has no journal of her own and is officially associated with no other State. A few counties on the east patronize a journal published in Minneapolis, a journal notably commercial in its general makeup, apparently published principally for private gain, and not conforming to the ethical standards of the American Medical Association. A few counties on the west subscribe to *Northwest Medicine,* the official journal of the States of Washington, Oregon and Idaho, published in Seattle. Therefore there is at present no journal wherein a Montana doctor may speak to the membership of his State Society, no journal wherein any writer may publish an article for the benefit of that great State. Inviting Montana to join us in a Rocky Mountain publication, we are to some extent in competition with journals which border on the east and west of that State, and which, from the point of view of railroad transportation, are closer in time and miles."

"Montana has in the past had far from the most satisfactory associations with medical journals. Being one of the few remaining States in the country not officially represented in any journal, it is natural that several publications have considered her 'fair game' and have tried to 'sell themselves' to her. The type of salesmanship that has been used is only too apparent to anyone discussing the journal situation with officers and leaders of the Montana Society. Certain other journals have evidently desired only Montana's good round dollars in subscriptions, offering in return only a medical journal published far away, by and for its local owners and with interests not Montana's. Therefore it is again natural that Montana finds it hard to believe there is no ulterior motive in our own invitation. It is hard for her to believe that Colorado is willing to give up the time-honored name and local identity of *Colorado Medicine* that has been built up proudly for almost thirty years, that the largest medical society in the Rocky Mountain region is willing to place itself on an equal footing with societies one-third and one-fourth its size to publish a greater medical journal that can truly represent the huge district where medicine still pioneers, that by our proposal we would make Montana an integral party to a publication representing Rocky Mountain medicine."

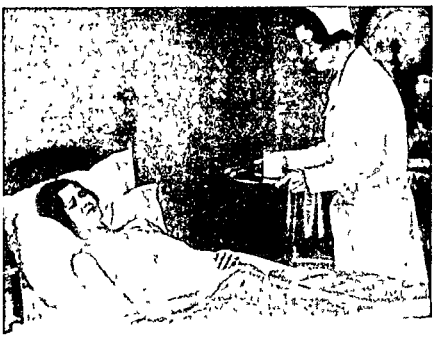
There is a great value in a publication representing a single State Society. The success of the dozens of journals of county medical societies would indicate that even the smallest State can make a success of its official journal.

WOMAN'S AUXILIARY IN NEW JERSEY

The physicians of New York State, who have not yet formed a Woman's Auxiliary to the State Medical Society, will be interested in the evidence afforded by the minutes of the Annual Meeting of the "Woman's Auxiliary to the Medical Society of New Jersey," as published in the Official Transactions, 165th Annual Meeting of the Medical Society of New Jersey, as a supplement to the August Journal. The minutes of the Auxiliary cover 22 pages, while those of the House of Delegates of the State Society fill 62 pages.

The membership is 727, while the dues collected amounted to only about seventy dollars. An item of the Treasurer's Report reads, "Annual Meeting Fund (State), $241.75," but this item does not appear in the report of the Treasurer of the State Medical Society.

The Publicity Chairman gave a descriptive report of social meetings, and relief. And the Chairman of the Welfare Committee reported on the promotion of subscriptions to *Hygeia*, the popular health magazine of the American Medical Association.



Thirteen county auxiliaries use four pages in reporting their activities which are largely social.

Ten pages were devoted to a discussion of the Constitution.

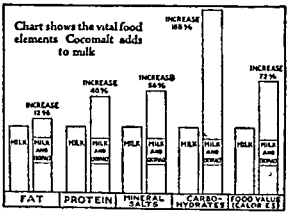
The Executive Board reported on the conditions in the County branches, one dormant one having been revived, and three disbanded. The chairman also reported:

"I have emphasized the value of keeping well informed; pursuing carefully the study programs issued from time to time by our National Auxiliary, reading regularly our own *New Jersey State Medical Society Journal*, spreading the use of *Hygeia Magazine*, keeping in general touch with the work that is being done in our Health Departments as well as the Health Educational work that is carried on in our local schools, public and private, all this effort that we may equip ourselves for the day, which I feel is in the offing, when the Woman's Auxiliary as a whole will be assigned to some concrete work which will make us an asset to the medical profession.

"Every Auxiliary has a direct responsibility as to the character of health information disseminated in the community and should be on the alert to forestall anything that might not savor of reliable instruction. Along these lines, the exposing of fraudulent advertising might well be considered an Auxiliary work. There are multitudes of people who accept as gospel the attractively gilded advertisements which confront us each day in our newspapers and magazines. Harmful, indeed, and a menace to unsuspecting readers. A united crusade against these fraudulent tactics would place each Auxiliary in a field of helpfulness worthy of its name."

When convalescents demur at the monotony of milk

Cocomalt not only renders it more palatable, but increases the food value over 70%



COCOMALT is a balanced combination of milk protein, milk minerals, converted cocoa, sugar, malt and eggs —to be added to milk, hot or cold. So mixed, the result is a delicious, chocolate flavor food drink—high in nutritive value and extremely palatable to convalescents, children and invalids.

Besides increasing the caloric value of each glass of milk 72%, Cocomalt contains Vitamin D in sufficient quantity to make a definite contribution to the anti-rachitic potency of the diet.

Cocomalt is made under modern, sanitary conditions —packed in air tight tin containers. Sold at grocery and drug stores. ½ lb., 1 lb., hospital 5 lb. can.

Vermont Healthatorium

Beautiful residence ideally situated in the most picturesque village of Vermont. Special care of the Convalescents and Invalids. Physician in attendance at all times. Opening July 1. Write or 'phone, Dr. W. J. McNamara, North Park Place, Fair Haven, Vt. Tel. Fair Haven —1.

FOR SALE—Office equipment and practice. Chelsea section, New York City. Especially built, modern office in apartment. Lease controlled. Well established, successful, general practice. Mostly office work, cash basis. Exceptional opportunity. Price, ¼ of average yearly income. E. B. Prout, M. D., 301 W. 24th St., N. Y. City.

SANITARIUMS—FOR SALE

We have a number fully equipped, some partially so, and properties that can be made suitable; New York, New Jersey, Connecticut. Send for list and give number of rooms wanted for patients (approximately), also location desired. Address Swift Realty Co., 196 Market Street, Newark, N. J.

PHYSICIAN—Desires a responsible position in private sanitarium or institution. Experienced in the treatment of mental cases, also drug and alcoholic. Best references as to character, ability, etc. Address Box 158. Care N. Y. State Journal of Medicine.

SANITARIUM OR PRIVATE HOSPITAL

There is a wonderful chance to establish a *Sanitarium* or *Private Hospital* in the suburbs of a town of North New Jersey, 25 miles from N. Y. City. Has 9 acres of landscaped grounds with three buildings having rooms for staff nurses, and fifty or more patients in single rooms—all buildings *completely furnished* in bedrooms, dining rooms, parlors, kitchen, etc (almost new). Full particulars as to why this place is to be sold. Address *Swift Realty Co.*, 196 Market St., Newark, N. J.

THE SUMMER-TIME USE OF VIOSTEROL

During the hot weather, when fat tolerance is lowest, many physicians have found it a successful practice to transfer cod liver oil patients to Mead's Viosterol in Oil 250 D.

Due to its negligible oil content and its small dosage, Mead's Viosterol in Oil 250 D does not upset the digestion, so that even the most squeamish patient can "stomach" it without protest. There are at least two facts that strongly indicate the reasonableness of the above suggestion: (1) In prematures, to whom cod liver oil cannot be given in sufficient dosage without serious digestive upset, it is an incontrovertible fact that Viosterol in Oil 250 D is the antiricketic agent of choice. (2) In Florida, Arizona and New Mexico, where an unusually high percentage of sunshine prevails at all seasons, Mead's Viosterol in Oil 250 D continues increasingly in demand, as physicians realize that sunshine alone does not always prevent or cure rickets.

Mead Johnson & Company, Evansville, Ind., invite you to send for samples of Mead's Vioserol in Oil 250 D for clinical use during the summer months to replace cod liver oil. See page ix.—*Adv.*

HOW TO CORRECT DIARRHEA

After a starvation period of twelve to twenty-four hours on boiled water or gelatin water (1/3 oz. of gelatin to one pint of boiled water), the infant should be given Protein S.M.A. (Acidulated (diluted 4 level tablespoons with 9 ounces of water, and without any additional carbohydrate.

	1st Day	2nd Day	3rd Day*
Severe cases ..	3 oz.	6 oz.	9 oz.
Medium cases..	10 "	15 "	20 "
Mild cases ...	15 "	30 "	

*Until the proper amount for their age and condition is reached, which is 200 c.c. per kilo of body weight per twenty-four hours, or three ounces per pound of body weight per twenty-four hours. However, the total twenty-four hour intake need not go above thirty-two to thirty-five ozs. or 960 to 1050 c.c.

After 48 hours or when the stools become normal, SMACO (400) Maltose and Dextrins (Spray Dried) should be added gradually, beginning with one oz. to the quart, and increasing until the infant is gaining steadily in weight. In certain cases, it may be necessary to increase the carbohydrate to a total of 12 to 15% (3 to 4 oz. of carbohydrate to the quart). See page xv.—*Adv.*

LIVER EXTRACT—LILLY

A review of the recent literature on the action of Liver Extract No. 343 in the treatment of pernicious anemia, suggests a number of generalizations:

1. That the optimum maintenance dosage is an individual consideration which can be determined accurately only by repeated blood examinations by the physician, and that a patient whose blood count has been brought to normal may continue for a year or more on a dosage of potent substance that is less than the required maintenance dose, but that eventually the need of a higher maintenance dose will become evident.

2. That during infection and fever it must be expected that the hematopoietic response will be inhibited but that an adequate dosage of liver extract should nevertheless be continued.

3. That if single massive doses of liver extract are given, the excess is not necessarily wasted, but may continue for a limited time at least to give results similar to those to be expected from a dosage of three vials daily.

4. That "the average gain in red blood-cells at the end of one month's treatment bears an inverse relation to the level of the red blood-cells before treatment was begun," and that in uncomplicated cases the number of red blood-cells produced at the end of one month by a daily dosage of three vials of Liver Extract No. 343, is essentially the same as that produced by higher dosages of four to ten vials per day.

Liver Extract No. 343 is supplied through the drug trade in boxes containing two dozen vials of powdered extract. The contents of each vial represent material derived from 100 grams, or about 3½ ounces, of fresh raw liver. See insert.—*Adv.*

POISON IVY

A new poison ivy treatment, in the form of a balm prepared according to a formula by Dr. Robert Morris of New York, is now being offered the drug trade by E. R. Squibb & Sons.

It is said that the new preparation contains, in addition to certain well-known remedies for ivy poisoning such as zinc oxide, methyl salicylate and phenol, a newly discovered vegetable solvent for rhus poison.

According to the manufacturers the new balm is effective in treating the poisoning in all its stages and that it is a remedy for infection from not only poison ivy but from poison oak and related plants also and for bites of insects, ticks and mites.

Packed in collapsible tubes, the new product is convenient to handle and to apply. The balm whose function is essentially to absorb the poison is applied to the affected areas of the skin allowed to remain there for fifteen minutes and is then washed off with common laundry soap. A second application, to remain longer, is advised.

The new remedy is in addition to already-established Poison Ivy Toxol Squibb and the Poison Oak Toxol Squibb which have been on the market for some time as an effective subcutaneous treatment. See page viii—*Adv.*

CREST VIEW SANATORIUM

Charmingly located, beautifully appointed; in the hilly country one and a half miles from Long Island Sound where the air is tonic. Quick drive from New York City. Truly homelike, no institutional appearance. See page xxv.—*Adv.*

NEW YORK STATE JOURNAL of MEDICINE

PUBLISHED BY THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

VOL 31, No. 19 NEW YORK, N. Y OCTOBER 1, 1931

THE MATERNAL MORTALITY RATE COMPUTED AND STANDARDIZED BY A NEW METHOD*

By ROBERT J LOWRIE, M D, NEW YORK, N. Y

THE high maternal mortality rate in the United States has now become one of the favorite topics of the lay press, and is one of the chief planks in the midwifery cause

Custom has decreed that the rate of death due to pregnancy and childbirth—the maternal mortality rate—be expressed as the number of maternal deaths per thousand babies born alive Thus 6 1, the rate quoted for the United States birth registration area in 1928, means that 61 mothers perished for every 10,000 babies born alive For the same year in some other countries, the figures are as follows Scotland, 7 0, England and Wales, 4 4, Netherlands, 3 4

How is the actual number of maternal deaths ascertained? Obviously every death certificate on which there is mention of pregnancy or childbirth cannot count as a maternal death, for pregnancy and childbirth are not infrequently complicated by cardiac disease, hyperthyroidism, tuberculosis, etc Physicians actually in attendance upon fatal cases often find it difficult to distinguish between the actual and the contributing causes of death This difficulty is magnified in emergency cases where there has not been adequate antepartum examination Surviving relatives often furnish meager assistance and autopsy is usually refused In short, the physician "does the best he can" with the certificate

In a straightforward case of death, for example in hemorrhage due to placenta previa, the cause is purely obstetrical However, where the patient dies for no apparent reason, to what degree is the death obstetrical and to what non-obstetrical? I recall a case of death three hours after delivery in an apparently healthy woman who ran an uneventful course and then just died What is the physician going to put on the certificate here?

Where there is a joint cause of death the question is again complicated For example, a woman dies on the 15th day postpartum, easy forceps delivery of normal child, fever 100 8 to 104 6 after third day, signs of congestion in the right lung, history of a questionable tuberculosis six years previously, no x-ray, no sputum nor blood examination, no autopsy Who can say whether the fever was due to puerperal sepsis, pneumonia or to lighting up of the alleged tubercular condition? If the Bureau of Vital Statistics interprets the exitus as being caused primarily by tuberculosis, then it is not classed as a maternal death If, however, the evidence favors sepsis or pneumonia then it is called a maternal or puerperal death

The physician's statement on the certificate as to primary and contributing causes of death, that is, whether or not the pregnancy and childbirth were the cause, is not necessarily final This decision rests with the Vital Statistician who is guided by the International List and Classification of Causes of Death These say, in part

"When one of these puerperal causes appears in conjunction with some non-puerperal cause on a death certificate, the death is classified according to definite rules irrespective of the order in which the causes are stated, or the apparent assignment as primary or contributory which the physician in attendance may have indicated"

That even these rules are at times inadequate may be surmised from the following excerpt regarding exceptions

"None of the rules are absolute, but all are subject to exceptions which may vary according to local usage"

We might well ask which determines whether the woman died of childbirth—the statement of the attending physician, the personal decision of the vital statistician, the international code of rules or the exceptions to these rules It is, therefore, difficult to see how any system of rules could effect a consistent classification of causes of death from information ultimately available

* Read by invitation at the April 1931, meeting of the New York Academy of Medicine Section of Obstetrics and Gynecology

to the vital statistician. And is it not logical to conclude that if two vital statisticians from two different states or countries were confronted with the same collection of death certificates, their death rates might well vary within wide limits? In fact, the League of Nations in their publications have shown a number of reasons why international statistics are not comparable. In spite of this highly probable disparity, the maternal death rate is computed to within one-tenth of one per cent, viz.: 2.6, 6.2, etc.

Is there not a better way of ascertaining the number of women who die of pregnancy and childbirth? If, in a given area there were 10,000 people alive at the beginning of an interval of time, say one year, and if during that interval 125 of these individuals died, then we say that the crude or general—and therefore real, death rate per 1,000 is

$$\frac{125}{10{,}000} \times 1{,}000 = 12.5$$

The real death rate is then the fractional ratio giving the relation between the number dying during an interval of time (the numerator) and the number alive at the beginning of that *same* interval (the denominator). The real death rate per thousand in a given interval may be stated in general as

$$\frac{\text{No. dying during an interval}}{\text{No. alive at beginning of same interval*}} \times 1{,}000 \quad \ldots\ldots\ldots (1)$$

The maternal mortality rate, however, as noted above, is the number of maternal deaths per 1,000 live births, and may be written

$$\frac{\text{No. of maternal deaths during interval}}{\text{No. of live births in same interval}} \times 1{,}000 \quad \ldots\ldots\ldots (2)$$

(The interval referred to is usually one year.) For example, if to 100,000 pregnant women during a year in some area, there were 96,000 babies born alive and if 518 mothers died of causes primarily due to pregnancy and childbirth, then we say that the maternal mortality rate for that year was 5.4 per 1,000 live births, viz:

$$\frac{518}{96{,}000} \times 1{,}000 = 5.4 \ldots\ldots\ldots (2a)$$

In (1), the real death rate, note that the numerator and denominator refer to the *same* period of time and furthermore that all elements of the numerator are also contained in the denominator. In the case of (2), the maternal death rate, this does not hold true, for the numerator (maternal deaths) takes into account the whole period of gestation while the denominator (live births) necessarily refers to practically only the last third of the gestation period.

Let us refer to the example leading up to (2a). It is quite possible, for several reasons, that the proportion of "live births" be less and yet no more mothers succumb. This circumstance raises the rate for: suppose that because of more stillbirths, miscarriages, ectopics, and a greater number of maternal deaths with fetus in utero, the number of live births was only 92,000 instead of 96,000, and also that only 90% of the births were registered, then the maternal death rate from the *same* number of maternal deaths in the *same* number of women is

$$\frac{518}{82{,}728} \times 1{,}000 = 6.3$$

Hence, quite independent of the number of deaths in mothers, the maternal death rate as calculated by this method:

1. Increases with deficiency of birth registration.
2. Very probably increases where there is a high proportion of cases which do not terminate in "live birth," viz: stillbirth, abortion, miscarriage, ectopic, mole and maternal death with child not born.

Can we not discover a more accurate method of arriving at the maternal death rate? If during a widespread influenza epidemic we isolated in one group all individuals who had this disease and in another all those who did not have it, and if it was found that the death rates per 1,000 in the influenza and non-influenza groups were 25 and 10 respectively, then we could rightly say that the mortality rate due to influenza was 15 per 1,000. Let us see if we can not utilize this simple principle in the computation of the rate of maternal mortality.

In order that the reader may not become too involved in the mathematical equations these are placed in the appendices and only the results with sufficient explanation to preserve the sequence of events will appear in the body of the article.

Registration of *non-viable pregnancies* (gestation under 28 weeks) abortions, miscarriages, etc.—is woefully incomplete and the number of women in whom these occur is not definitely known.

In our problem we shall consider women pregnant 28 or more weeks (*viable pregnancy*); these we shall arbitrarily call the *childbearing group*. Women having a non-viable pregnancy and those in the age group 15-44 not pregnant will be arbitrarily designated as the *non-childbearing* group.

Bureaus of vital statistics have record of births

* In population statistics the mid-year population is used as the denominator in this ratio.

but not of the number of women giving birth The number of women in the childbearing group may be found from the number of registered live births* (Appendix) This appears in column 3 of Table I As the number of women giving birth outside the age limits 15-44 is relatively small no appreciable error is incurred by assuming all pregnancy cases to be in the 15-44 group

We recall from (1) above that the general death rate was the relation between the number alive and the number dying within a given interval of time If we think of this definition in terms of women bearing children, and deaths in this group to the end of one month postpartum, from *any* cause, then the death rate in the childbearing group is

TABLE I

New York City 1930

(1) Live births registered	(2) Live births corrected for a deficient registration of 1 per 1000	(3) Childbearing group, i e , women with viable pregnancy	(4) Females ages 15-44 inclusive	(5) Non-childbearing group 1 Women with non-viable pregnancy 2 Women in age groups 15-44 not pregnant Column (4) less Col (3)
122,811	122 934	124 146	1,664,639**	1 540 493

The number of deaths in pregnant women is of course found in the corresponding number of death certificates By virtue of some extra work on the maternal death certificates for New York City, 1930, these have been classified into viable and non-viable deaths, and are entered in Table II as columns (1) and (5) respectively

Practically all maternal deaths which are primarily caused by pregnancy or childbirth have occurred by the end of one month after birth The proposed method of computing the death rate excludes, for purposes of standardization, those very few postpartum deaths taking place after one month

$$\frac{\text{No of women in childbearing group}}{\text{No of deaths in childbearing group}} \times 1{,}000$$

The numerator is column (1) of Table II and the denominator is column (3) of Table I Hence the death rate per 1000 in the childbearing group is

$$\frac{515}{124{,}146} \times 1{,}000 = 4\,15 \qquad (4)$$

TABLE II

New York City 1930

(1) Deaths in childbearing group to end of one month after birth	(2) Deaths from all causes in females ages 15-44 inclusive	(3) Deaths in non-childbearing group Column (2) less Col (1)	(4) Deaths in women with viable pregnancy who died with child not born	(5) Deaths in women with non-viable pregnancy
515***	7 299	6 784	68	152

* As the number of stillbirths is usually in excess of the total of multiple births there are always more mothers than there are live births

** Obtained from the relation of number of females 15 44 shown in the 1920 census to the total population as given by the 1930 census

*** This figure includes deaths beyond one month after birth as the records available did not always indicate the time elapsing between parturition and death The effect of this is therefore to overstate slightly the rate which would apply to a one month postpartum limit

This means that in this series of cases, of every 100,000 who had a viable pregnancy, 415 succumbed either during pregnancy or within one month postpartum. But in how many of these women was death caused or hastened by heart disease, tuberculosis, pneumonia, etc, etc.—diseases from which they might have died even if not pregnant?

The death rate in the non-childbearing group refers to the whole year while that of the childbearing group, by our definition, applies to only 16 weeks, namely the last 12 weeks of pregnancy and the first four weeks after birth. Therefore, if we are to compare these rates we must multiply the former by that fraction of the year through which the childbearing rate applies. The death rate in the non-childbearing group is the relation between the number of women not bearing children (Col. 5 of Table I) and the deaths in this group (Col. 3 of Table II) and is

$$\frac{16}{52} \times \frac{6{,}784}{1{,}540{,}493} \times 1{,}000 = 1.35 \quad \ldots\ldots\ldots (5)$$

We now have the death rates of two groups of women in age class 15-44 who, in general, differ only as to pregnancy or status in pregnancy. Is not the difference between their death rates the mortality due to pregnancy or childbirth per se? Combining (4) and (5) in the form of a difference, that is, indicating that (5) is to be taken from (4), and placing underneath the computed rates per 1,000 we have:

$$\frac{515}{124{,}146} \times 1{,}000 - \frac{16}{52} \times \frac{6{,}784}{1{,}540{,}493} \times 1{,}000 \quad \ldots\ldots\ldots (6)$$

$$\frac{4.15}{1{,}000} - \frac{1.35}{1{,}000} \quad \ldots\ldots\ldots\ldots (7)$$

$$\frac{415}{100{,}000} - \frac{135}{100{,}000} = \frac{280}{100{,}000} \quad \ldots\ldots\ldots\ldots (8)$$

The interpretation of (8) is: *"In this series,* of every 100,000 who entered the period of viable pregnancy, 415 died either during pregnancy or within one month after birth; and of these 415 there were 135 whose death could not be attributed to pregnancy or childbirth, but rather to some other condition or disease associated with it. The remainder, 280, are those women whose deaths were due primarily to pregnancy or childbirth, other conditions as heart disease, tuberculosis, etc., if present, merely playing a secondary rôle.

We now see that in our series of cases, out of 415 deaths in women with viable pregnancy only 280 or 68% of these deaths were due to pregnancy or childbirth per se. In the 152 deaths in women with non-viable pregnancy (Col. 5 of Table II) were only 68 per cent of these caused by pregnancy or childbirth? If so, then the number of maternal deaths for all periods of gestation was 68% of (515 + 152) or 451. Hence the maternal death rate, based on the number of maternal deaths per 1,000 live births, is 3.7. The maternal death rate for New York City, 1930, as reported by the Bureau of Records is 5.43.

Our series of cases is sufficiently large and heterogeneous to be representative, and 1930 is probably little different from any other year. Is the maternal mortality rate of New York City being nearly one-third overstated? Is the maternal death rate of the whole United States overstated?

The true mortality rate in women pregnant under 28 weeks cannot be computed because of the faulty registration of abortions, miscarriages, ectopics, etc. We do the next best by relating the number of deaths in this non-viable group to the number of women in the non-childbearing group. In our series of the total 667 deaths, 152 of these (Col. 5 of Table II) were in women pregnant under 28 weeks. The number of women in the non-childbearing group from Column 5 of Table I is 1,540,493. Hence

$$\frac{\text{Deaths in women with non-viable pregnancy}}{\text{Women in non-childbearing group}} \times 1{,}000 \quad \ldots\ldots\ldots (9)$$

$$= \frac{152}{1{,}540{,}493} \times 1{,}000 \quad \ldots\ldots\ldots (10)$$

$$= 1 \text{ per } 10{,}000 \text{ (approximately)}$$

This means that in New York City in 1930 for every 10,000 women in the non-childbearing group there was one who died while pregnant under 28 weeks. Note that the mortality in this group bears no particular relation to that in the childbearing group.

Maternal Death Rates Based Upon Small or Unrepresentative Samples.—Hospitals, maternal welfare or visiting nurse organizations, etc., sometimes quote their maternal death rates. The primary object in computing a death rate is to compare it with that of some other institution or area. If the series of cases are relatively small, or if there are gross differences as to the types of patient, circumstances under which medical and nursing care was rendered, etc., then comparison of death rates may lead to unwarranted conclusions.

In Table III is shown the maternal death rates (uncorrected) for certain periods of consecutive months or years in the ten years 1921-30 at the Manhattan Maternity and Dispensary, New York City. This Maternity institution in addition to having a private patient service (about

25%) serves a tenement house area. The majority of the mothers are clinic or dispensary patients and during the years 1921-30 approximately 30% of the confinements took place in the homes.

TABLE III

Maternal Death Rates Over Long and Short Periods

Period of consecutive months or years	No. of live births	For any period of gestation: No. of mothers who died	For any period of gestation: Maternal death rate per 1,000 live births	Line
Jan., 1927, to July, 1930	5,029	9	1.8	1
Year 1927	1,437	1	0.7	2
Sept., 1926, to Oct., 1928	2,955	2	0.7	3
May, 1926, to Feb., 1929	3,844	9	2.3	4
Jan., 1921, to July, 1922	2,200	11	5.0	5
Years 1921-30 inclusive	13,505	34	2.5	6

From Table III (line 2) it is observed that the maternal death rate in 1927 was 0.7. This is roughly one-ninth of the rate for the whole United States in the same year; but how erroneous it would be to assert that if the childbearing women of the United States could avail themselves of the services typical of this institution, then eight out of nine maternal deaths could be prevented. Note that in the series of 2,955 births (line 3) with two deaths, the death rate was 0.7, but if the period be enlarged by only 7 months, or from 2,955 to 3,844 cases (line 4) then there are 7 deaths added, bringing the rate from 0.7 to 2.3. Hence an increase of 30% in the number of cases raises the maternal death rate 334%. In 19 months there were 2,200 cases with 11 deaths, a rate of 5; though the personnel of the institution would be rather reluctant to admit that a rate of 5 was an index of their efficiency. The rate of 2.5 for the whole ten years is undoubtedly a just showing for this hospital. Rates based upon a short series may or may not represent the whole story. Hence the fallacy of generalization from a mere handful of deaths.

In regard to maternity organizations, a certain number of patients who register drop out of the antepartum clinic and are cared for elsewhere. Others are confined by the service on which they registered but remain under observation for only a brief period of time. Again, maternity services very often transfer to gynecological services cases such as ectopic, mole, abortion requiring operative interference, etc. Sometimes for economic reasons, or because of lack of facilities to handle pathological or septic cases, a patient may be transferred from either hospital or home to a large charity hospital. Physicians, visiting nurses and social workers interested in follow-up work are well aware of the fact that there is always a group of patients whose record as to their status—alive or dead—on the 30th day after birth does not appear on the records of the institution originally responsible. From what has been said above, a certain number of the group not followed up are known to have died; in others this may eventually be surmised. These deaths, however, appear on the roster of the Board of Health of the community, and of the state or country of which the series of cases under study comprise a mere sample. Patients with pathological conditions of early pregnancy such as abortion, ectopic, mole, and those requiring sterilization, may be cared for on gynecological or surgical services without first applying to any maternity organization. Here again a certain number of deaths are added to the record of the country or community, but do not appear of that of any maternity institution.

From what has been said, it can be seen that the country or community has an *unselective* death rate, while the relatively small sample presented by the maternity organization gives rise to a *selective and necessarily lower death rate.* The degree of selectivity depends upon many different factors and cannot be exactly measured. Because of the number and variability in the effect of these factors, comparison of the selective with the non-selective rate may lead to error. An instance of this is seen in the comparison of the low maternal mortality rate in New York City in a group of women who had highly specialized prenatal and visiting nurse care, with the corresponding rate for the whole United States. It is granted that if every childbearing woman in the country at large had good prenatal and visiting nurse care, the number of deaths would be definitely less; but, for the country in general, the majority of women in childbirth would still be short the advantages of the telephone, the ambulance, the elaborately equipped maternity hospital, the highly trained obstetrician, the blood transfusion, etc., etc., all of which operate to save life. Therefore the contention that, given a type of prenatal or visiting nurse care, two-thirds of the maternal deaths of the United States could be prevented, is based on theoretical considerations and still awaits proof.

Sphere of Application of Proposed Method.—Our study was limited to the period of viability and one month postpartum. Other limits of gestation, six months, eight months, etc., for which we can compute the number of women, and other limits postpartum—ten days, twenty-one days, etc., could have been chosen and a similar problem worked out.

The population census lists for the separate age groups 15-19, 20-44, etc., the number of persons, deaths, and births. Hence the maternal mortality rates in the various groups can be computed and if desired, compared with other countries.

Is it not possible that one could secure samples from different areas throughout the country and from these obtain an aggregate or average sample which would be fairly representative of the whole country? The proportion of fatal viable cases, as well as the time of death in relation to delivery or expected delivery could possibly be obtained by inference from the total certificates which recorded the period of gestation, or by communication with the physician. Hence, just as we have done in New York City, we could very probably compute for the whole country the mortality due to pregnancy and childbirth per se.

The proposed method of computing the mortality due to pregnancy and childbirth is impersonal and mechanical. The precise allocation of deaths as to whether or not they were caused primarily by pregnancy or childbirth is *inherent in the method.* The personal equation of the physician or the vital statistician, and the errors incident to the absence of uniform application of the International Code are almost entirely removed. Cold figures of population, births and deaths are the predominating elements. These are a matter of definite record in every country and the primary dependence of the new method upon standard data lends rigidity and uniformity to maternal mortality rates. The "measuring rod" for all is the same. It has just been stated that the personal equation is "almost" entirely removed. It is still possible, however, under the present regime of certification that the death certificate of a pregnant woman will not indicate the period of gestation, or whether death took place before or after delivery. The writer would like consideration by the Bureau of Vital Statistics of the following suggestions:

Birth Registration

1. The same certificate be used for live and stillbirths.
2. A direct question on the certificate as to whether the child was BORN DEAD or BORN ALIVE.
3. A direct question as to whether it was a *single, twin, or triplet birth.*
4. A statement on the certificate giving the period of gestation in weeks, or other standard units.
5. The completeness of registration of live births be checked up from infant deaths, at periodic intervals, as seems necessary.
6. In case of birth in an institution the name of this to be noted on the certificate.

Death Certification

1. In case of females in age group 12-50, a query on the certificate as to whether or not pregnancy was present, or whether deceased had "given birth" during the month immediately preceding death.
2. In case of death in an institution, the name of this to be on certificate.

By following the various steps shown in Tables I and II, equations (3) to (8), and the Appendix, the death rate in any area may be worked out. The general formula for the death rate due to pregnancy or childbirth per se is also developed.

Summary

The employment of the proportional algebraic equation to determine the number of childbearing women from a given number of live births, and the method of expressing the death rate in pregnancy and childbirth per se as the difference between the mortality rates in the child and non-childbearing groups, I believe to be new and original.

The present method of computing the maternal mortality rate—number of maternal deaths per 1,000 babies born alive—it is thought, is subject to two main sources of error, the first due to the inability of death certification to separate causes of death into primarily maternal and non-maternal, and the second due to the variation of the element of "live births." These two factors *always* come to mind in the comparison of maternal mortality rates of different countries, states, etc. I have utilized the proportional algebraic equation in conjunction with the principle of sampling to ascertain from a given number of live births the corresponding number of women *with viable pregnancy. This, divided into number* of deaths in women with viable pregnancy gives the death rate in the childbearing group of women. If from this rate the rate in the non-childbearing group be deducted, the difference, I believe, is the true mortality due to pregnancy and childbirth per se. The method, depending mainly on fixed quantities—population figures, births, deaths and time, can be used for *standardization* of the rate so that for all countries there is a common yardstick. The method may also be used to test the accuracy of the present method of calculating the rate—maternal deaths per 1,000 live births—in so far as this rate de-

pends upon the estimate of maternal deaths The translation into algebraic symbols gives the mathematical formula, though obviously this formula must be used only in fairly large communities, countries, states, etc It was further observed that there was no way of arriving at the true death rate in women pregnant in the period of non-viability, but that only a rate in terms of population could be given

Sweeping generalizations from the rates in small samples usually lead to misinterpretation It has been pointed out that the death rate of a country, state or large center is the true representative or non-selective rate while that of the maternity organization—hospital visiting nurse service, etc—is necessarily the selective rate, and one which does not represent conditions in general A low maternal death rate directly attributable to specialized prenatal and visiting nurse care given in a large metropolis does not imply that the maternal death rate in the whole United States could be reduced to the same level The point must be stressed again that many factors should be taken into account before comparisons are made between any two rates Prompt and accurate certification of not only the fact—but also the gestation period—of births and deaths is of paramount importance

Appendix

Bureaus of vital statistics of local boards of health have record of births but not of the number of women giving birth The latter figure we must know in order to obtain the real death rate in women bearing children If registration of stillbirths were sufficiently complete, then the number of women in the viable or childbearing group would be the number of viable live and viable stillbirths plus the number of women dying with viable child not born, *less* one and two respectively for each set of twins and triplets Unfortunately under our present system of registration these ideal figures are not available

An institution, such as a maternity hospital, can have complete record not only of the total of births but also of the period of gestation of each Furthermore, to a given number of live births of any period of gestation there corresponds a certain number of women in the childbearing (viable) group The ideal conditions possible in a maternity hospital tend to save life On the other hand, the difficult cases from which the bulk of mortality arises are liable to find their way into the institution Hence two factors exist, the one tending to raise and the other to lower the number of live births I think that we could say that the proportion of live births in the average maternity hospital is comparable, within reasonable limits, to that of the community which it serves Hence on the assumption that we can get from the records of the institution a sample representative of the community, we may say that the number of childbearing women per 1,000 live births in the community is approximately the same as the corresponding ratio for the sample

In Table IV are shown two series The large or New York City series is for the year 1930 The sample series refers to consecutive live births at the Manhattan Maternity and Dispensary, New York City

TABLE IV

Source	Women bearing viable children	No. of live births corrected for deficient birth registration*
New York City Series	W	122,934
Sample Series	5,640	5,588

From what has been said above about proportion we may apply the *proportional algebraic equation* to the data of Table IV and write

$$\frac{W}{5640} = \frac{122\,934}{5,588}$$

$$W = 5640 \times \frac{122\,934}{5,588}$$

$$= \frac{5,640}{5,588} \times 122,934$$

$$= \frac{1,009\,3}{1,000} \times 122,934$$

If now we add to this the number of women with viable pregnancy who died with child not born (68), we have

$$W_c = \frac{1,009\,3}{1,000} \times 122,934 + 68 \qquad (9)$$

$$= 124,146 \qquad (10)$$

= No of women with viable pregnancy *corresponding* to 122,934 live births in New York City in the year 1930

This result is Column 3 of Table I

In 1930 in New York City the ratio of childbearing women per 1,000 live births was 1009 3 for the 4 029 cases at the Manhattan Maternity, Nursery and Childs, and the City Hospital Doubtless other samples would yield a comparable ratio *Hence the maternal death rate of 2 80 per 1,000 women is representative*

* A correction of one per 1000 for deficient birth registration affects the end result very little The correction is made to demonstrate the routine of the proposed method of computing the number of women in the childbearing group The sample series from the institution of course needs no correction

FORMULAE

If in (9) we designate 1,009.3 = W_1 = the No. of childbearing (viable) women per 1,000 live births in a representative sample series; 122,934 = L = No. of live births (corrected if necessary for deficient birth registration) in the area from which the sample is taken; 68 = Df = No. of childbearing women who died with child not born, then

$$Wc = \frac{W_1}{1{,}000} \times L + Df \quad \ldots\ldots\ldots\ldots\ldots\ldots (11)$$

= No. of women with viable pregnancy in area corresponding to L live births.

Equation (6) may be written:

$$\left\{\frac{515}{124{,}146} - \frac{16}{52} \times \frac{6{,}784}{1{,}540{,}493}\right\} \times 1{,}000$$

Refer to (1) above also to Tables I and II and designate as follows:

Wc = 124,146
= No. of childbearing women in an area, as obtained by (II) above.

Dc = 515
= No. of deaths—from whatever cause—in Wc, obtained from death certification.

Wnc = 1,540,493
= No. of women in non-childbearing group, i.e., women in the age group 15-44 inclusive less those in the childbearing group.

Dnc = 6,784
= No. of deaths in women in the non-childbearing group, i.e., the total of deaths from *all* causes in women of ages 15 to 44 inclusive, less the number of deaths in the childbearing group.

$f = \frac{16}{52}$
= fraction of the year—last 12 weeks of pregnancy plus the first 4 weeks after birth—over which Dc applies.

Then

$$\left\{\frac{Dc}{Wc} - f\,\frac{Dnc}{Wnc}\right\} \times 1{,}000 \quad \ldots\ldots\ldots\ldots\ldots\ldots (12)$$

is the mortality due to pregnancy or childbirth per se. Obviously the method of computation might give erroneous results if applied to a small number of cases. It has its greatest use in the computation and standardization of rates in countries, states, and reasonably large communities.

IDIOPATHIC CHOLEDOCHUS CYST: REPORT OF A CASE*

By FRANCIS M. O'GORMAN, M.D., LOUIS CHELY, M.D., and CLARENCE F. HEYDEN, M.D., BUFFALO, N. Y.

NEARLY all textbooks and systems of surgery mention idiopathic cyst of the common bile duct, but it is very rarely encountered in the practice of even large clinics, as may be seen from the fact at the Mayo Clinic where there have been over 17,000 operations on the biliary tract in the last twenty years or so, a true cyst of the common duct was encountered but once and in the literature of the whole world from 1830 down to the present day there have been only 93 case reports.

We believe that we have here a case of true

* Read at the monthly meeting of the Staff of the Buffalo Hospital of the Sisters of Charity, in March, 1931.

idiopathic cyst of the common duct in a girl of 8 years She was admitted to the Sisters' Hospital on Sept 4, 1930, and for four days we studied the case

History

Until April of this year (1930) she was a perfectly normal girl except for mild attacks of measles and scarlet fever earlier in childhood Two things happened to her at this time, and so gradually that friends of her mother noticed that the girl was getting jaundiced, and that her abdomen was getting a bit distended As this grew more noticeable and the stools became clay-colored, a doctor was called and a diagnosis of acute catarrhal jaundice was made She improved a little and her parents sent her to the country to get more fresh air and sunshine Instead of improving, her jaundice became more marked, the abdominal distention increased and the stools which had regained their normal color during her early stay in the country again became clay-colored

Physical Examination

At no time during the entire period of observation at home had the child shown any evidence of constitutional disturbance Her nutrition was good and the girl was as active as any other normal youngster of 8 years So that during the four days that we observed her we see a little girl anxious to get out of the hospital in time for next Sunday's picnic She has a normal temperature, pulse and respiratory rate The mucous membranes and skin are only moderately jaundiced, the abdomen is enlarged quite unmistakably, and we could palpate what felt to us like the right lobe of the liver filling the right upper quadrant It seemed quite firm, moved with respiration, and was flat on percussion The spleen was also definitely palpable No free fluid was present There was an increased tracery of subcutaneous veins over the abdominal wall, but no evidence of purpuric spots or petechiae All other systems were normal

Laboratory

The Wassermann was negative A von Pirquet tuberculin test was negative With the dye given by mouth there was no visualization of the gall bladder whatever The test was repeated with negative results There was a shadow that extended below the right costal margin that the roentgenologist, interpreted as an enlarged liver There was nothing abnormal about the bleeding the clotting or the fragility of the blood There was no anemia and the stained smear showed no abnormal red or white cells She had nearly 15,000 white cells but the poly percentage was only 63% The Van den Bergh gave the usual biphasic reaction seen in an obstructive jaundice During her four days in the hospital her stools were at all times clay-colored, and pulse and temperature remained on the normal line

Pre-Operative Notes

She was allowed to go home with the impression that this was a low-grade cholangitis and she was put on KI A week later, however, the signs had changed, and the mass in the right side of the abdomen became so large that an exploratory laparotomy was decided upon at once Going over the child before operation we were impressed first by the total absence of all constitutional disturbance She was still moderately jaundiced perhaps a little lighter than a week before One thing stands out, however even on inspection and that is the marked protuberance in the right upper quadrant extending even into the lower When we come to feel of the child's belly we no longer wonder whether we are dealing with an enlargement of the liver, for this is a tumor the size and shape of an infant's head It is smooth, firm but not hard, and has the tense elastic feel of a cyst It is not very tender and can be displaced from side to side giving the impression that it is anchored by some sort of short mesentery to the posterior parietal wall It definitely did not move with respiration, and there was a definite limit of the tumor upwards so that we doubted that it was part of the liver The spleen was felt as before An enema just before operation returned a dark brown normally colored stool A physician that limits his practice to children, saw the girl just before the operation and upon the above findings made a diagnosis of hypernephroma of the kidney

Operation

A right rectus incision was made and the abdominal cavity opened in the usual way Immediately a large cystic mass the size of a grapefruit popped into the incision Omentum adherent to it was easily separated The duodenum was pushed to the left and adherent being separated with a little difficulty The liver was a little enlarged and definitely cirrhotic The gall bladder was so intimately surrounded by liver substance that only the fundus was visible, lying medial to the cyst The hepatic flexure of the colon was pushed downward so that the upper part of the cyst lay beneath the liver edge A trocar was now inserted into the cyst and a quart of dark green fluid bile was aspirated The sac was now opened a little wider and sponged out The lining was smooth and the walls very thin while bile was seen to flow from two openings in the upper pole With the finger, adhesions were broken up all around until finally there seemed to be two rather large ducts coming from the hilum of the liver and entering the upper pole

of the cyst. When the gall bladder was squeezed, the bile in it entered the cyst by way of one of the ducts. No common or cystic duct could be found and the gastro-hepatic ligament seemed to convey the hepatic trinity in a normal manner so that it was judged that the junction of the hepatic and cystic ducts was anomalously deep in behind the liver. The next procedure was to ligate these ducts, remove the cyst, and drain the gall bladder. A cigarette drain was placed against the ligated ducts and the belly closed in the usual way.

Post-Operative Notes

Immediately after operation the child began to get more and more deeply jaundiced, the stools became clay colored and remained so, the urine became darkly stained with bile pigment, and the dressings were saturated with blood and bile, until on the seventh day post-operatively, the biliary fistula was established, the dressings needed changing every four hours, her jaundice cleared, and the stools remained grey. At the end of two weeks she was out of bed, however, and was sent home with a biliary fistula. After another two weeks she was brought back to the hospital and a small catheter inserted into the fistula for about two inches. Pyelographic sodium iodide under pressure was injected and *x*-rays taken which clearly outlined a tract about four inches long leading into the fundus of the gall bladder. which drained a dilated cystic duct and many ramifications of the hepatic ducts in both lobes of the liver. As a result of these pictures we felt sure that the hepatic ducts drained into the cystic, and so into the gall bladder and fistula, and that when we removed the cyst we ligated the two ends of the common duct on either side of a congenital dilatation of the middle segment of the choledochus.

Her blood at this time contained 5,000,000 red blood cells, still showed 15,000 white cells with 80% polys. Platelets were normal. Only two and one-half minutes for coagulation. A Duke's bleeding time of 4 minutes was only slightly prolonged over the normal.

Second Operation

One month and a half after the first operation, the child returned to the hospital and was operated the next day. The fistulous tract was easily separated and dissected back to the normal upper part of the common duct although the junction of the hepatic, common and cystic ducts still could not be seen. Bile was flowing from the fistula constantly. The duodenum was easily mobilized in its first portion. The gall bladder fundus was opened and it was found that it extended well up behind the liver and was completely surrounded by liver. There was no bile in it, only a white mucoid material, and for this reason in making our anastomosis we included the fistula along with the gall bladder, sewing both into the duodenum. A Mikulicz drain was inserted and the belly closed. From the very first day, however, the wound drained bile and blood quite profusely. The child grew weaker and her stools became black and tarry, giving a 4 plus occult blood test. Peritonitis set in and the child died.

Necropsy

The operative incision was opened and enlarged, only a partial post mortem being permitted. Between the liver and the abdominal wall was a solid mass of fibrinous exudate containing both blood and bile, and ranging in thickness from ½ inch to 1½ inches, and extending upward as far as the coronary ligament of the liver. No bile was free in the peritoneal cavity, although the intestines were matted together with this plastic exudate. The capsule of Glisson was not thickened and a mild degree of the biliary type of cirrhosis was present. In size and weight the liver was slightly above normal. The spleen was a little enlarged and fibrous. The other organs were not remarkable and showed no other anomalies. The pancreas was normal and emptied into the duodenum through several small ducts but no prominent papilla of Vater. The anastomosis of the fundus of the gall bladder was in perfect shape, but the fistulous tract had slipped out of the duodenum, accounting for the immediate and profuse biliary drainage right after operation. On opening into the gall bladder it was found to be filled with solid blood clot, twice the normal size, with thick, indurated, chronically infected walls, draining through a short cystic duct into the hepatic duct, high up and behind the liver. The hepatic branches were traced into both lobes of the liver and were slightly dilated but not anomalous. The upper part of the common duct was found connecting with the fistulous tract. The lower portion of the common duct in the gastro-hepatic ligament could not be found, nor could we find the ampulla of Vater. The intestinal contents were black and tarry but no fresh blood was present. The entire intestinal mucosa was very hyperemic. Microscopically the gross findings were confirmed but nothing of interest added.

For the best discussion and the fullest report of cases that have occurred in the literature, one is referred to: Waller, Erik: Idiopathic Choledochus Cyst, *Ann. Surg.*, 66: 446-463 (Oct.), 1917. And more recently—Wilson, Henry V. P.: Choledochus Cyst, *J.A.M.A.*, 93: 399-400 (Aug.), 1930.

Next Annual Meeting, Buffalo, May 23, 24, 25, 1932

DISTRICT BRANCH MEETINGS

The Medical Society of the State of New York has always recognized the importance of the meetings of the District Branches throughout the twenty-five years of their existence. The parent society prints and mails the programs, provides a substantial sum of money for the expenses of each District, and assists in making and carrying out the programs. Also the officers of the State Society consider the assemblies to be opportunities for meeting the members socially and on intimate terms, thereby promoting an interest in Medical Society affairs both locally and state-wide. The example of the New York State Society in conducting the meetings of the District Branches is a model which other State societies are emulating and following.

INDEX TO REFERENCES TO THE GOVERNOR'S HEALTH COMMISSION

The NEW YORK STATE JOURNAL OF MEDICINE has carried all the news that was available regarding the Health Commission that was appointed by Governor Franklin D. Roosevelt on May 1, 1930. The Commission has held monthly meetings, and made extensive studies of public health matters in the State, with special reference to legislation for an increased participation of the State and local communities in assisting to provide medical service to all the people. The Commission decided to withhold publicity of its deliberations until it had reached some definite decisions. The Journal has therefore given the Commission but few notices, and these of only a general nature. For the sake of ready reference to the records of the Commission, the following index has been prepared, giving the notices which have appeared in this Journal:

1. Governor's conference on Public Health Education, Journal May 15, 1930, page 611.
2. Appointment of Health Commission by Governor Franklin D. Roosevelt, May 15, 1930, page 612.
3. Editorial note by President Ross, October 1, 1930, page 1167.
4. Appointment of Subcommittees of the Commission, January 1, 1931, page 39.
5. Preliminary statement of conclusions of the Commission, January 15, 1931, page 106.
6. Governor's Annual Message, January 15, 1931, page 109.
7. Abstract of Preliminary Report of Governor's Commission, February 15, page 230.
8. President Ross' Editorial comments on the Wicks-Hutchinson bill embodying recommendations of the Commission, March 15, page 355.
9. Legislative note on Wicks-Hutchinson bill, March 15, page 366.
10. President Ross' comments, April 1, page 415.
11. Another note, April 1, page 427.
12. Protest of Genesee and Rensselaer counties, April 1, page 428.
13. Governor's comments on the opposition, April 15, page 477.
14. Attitude of Speaker McGinnies and Senator Knight, April 15, page 499.
15. Opposition of Cattaraugus County, April 15, page 500.
16. Annual Report of President Ross, May 1, page 521.
17. Legislative Committee, note on Wicks-Hutchinson bill, May 1, page 584.
18. Discussion in the House of Delegates, July 1, page 826.
19. Meeting of Joint Committee on the Commission, October 1, page 1208.

AMERICAN COLLEGE OF SURGEONS

The Clinical Congress of the American College of Surgeons will hold its annual session October 12-16, 1931, in the City of New York. This is the fourth time the Congress will have come to New York, the others years being 1912, 1916, and 1924.

The story of the American College of Surgeons begins in the year 1910, when a number of prominent surgeons from all parts of the United States met in Chicago and held a Clinical Congress. A similar Congress was held in 1911 in Philadelphia. Those attending the 1912 Congress in New York discussed the problem of standards in two phases:

1. What constitutes a hospital?
2. What qualifications should a surgeon possess?

The Congress appointed a committee for the purpose of formulating standards of qualifications for both hospitals and surgeons. The need for the supervision and maintenance of the standards was so obvious, that the American College of Surgeons sprang into existence almost spontaneously, so that now even the smaller hospitals seek to conform to three standards:

1. All pathological material shall be examined by a competent pathologist.
2. A record of every case shall be kept in such a form that its full history is available.
3. Staff conferences shall be held at least monthly for the discussion of both morbidity and mortality.

The program of the annual Congress this year includes clinics in all the leading hospitals of Greater New York and Nassau County. The Congress will also hold evening meetings which will be addressed by leading surgeons from all over the United States. One feature will be exercises on the sixteenth when candidates for fellowship in the College will be received and initiated.

The headquarters of the Congress will be the new Waldorf-Astoria Hotel, on Park Avenue, between 49th and 50th Streets, New York, where also the evening lectures, demonstrations, exhib-

its, and dinners will be held. All the meetings are open to physicians, but admission to the clinics will necessarily be by card, for which a fee of five dollars will be charged. Dr. Charles Gordon Hoyt, President-elect of the Medical Society of the State of New York, is Chairman of the New York Sommittee, and Dr. John E. Jennings is Chairman of the Brooklyn Committee.

Any physician may obtain programs, admission cards, and other information by addressing the College at Room 501, in the Waldorf-Astoria Hotel.

GRADUATE FORTNIGHT OF THE NEW YORK ACADEMY OF MEDICINE

The Fourth Graduate Fortnight to be conducted by the New York Academy of Medicine during the two weeks beginning October 19, is an opportunity open to every physician in New York State. The subject this year is "Disorders of the Circulation." The program includes three features daily:

1. Afternoon clinics in thirteen hospitals of New York City, by ninety-three teachers
2. Exhibits and pathological demonstrations in the Academy building, with formal programs in the early evening.
3. Evening lectures by twenty speakers.

The features of the Fortnight are free, and every member of the Medical Society of the State of New York is welcome. A copy of the official program may be obtained by addressing the New York Academy of Medicine, 2 East 103rd Street, New York City.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

Dr. Didama: This Journal of October, 1906, contains an address by Dr. J. L. Heffron in memory of Dr. Henry Darwin Didama of Syracuse, who died October 4, 1905, aged 82 years. Dr. Didama was a recognized medical leader in Syracuse and throughout New York State. He served as President of the Medical Society of the State of New York, and was the first president of the New York Medical Association when it was founded in 1883.

Dr. Didama was a general practitioner—an internist he would be called today. He speaks of the alkaline treatment of rheumatism as follows:

"I read a paper on the use of acetate of potash in its treatment. It was entirely new to the Syracuse fellows. They had been using calomel and jalap and things of that kind and their patients never got well under six weeks, the time in which the disease would, in any event, have run its natural course. I told them of several patients who had gotten well under the acetate of potash treatment in a few days and they proceeded to bait me. 'What effect did it have on his pulse?' asked one; 'Did you look at his tongue?' asked another; 'How were his bowels affected?' asked a third. I saw that their purpose was to confuse me and I finally said, 'Gentlemen, there is no use asking me these questions for the only thing that I observed at all accurately was that the patient got well.'"

MEDICAL PROGRESS

Some Clinical Observations on Cancer.—W. B. Cosens, writing in the *Practitioner,* August, 1931, cxxvii, 2, states that in a practice of over forty years two special clinical facts have come under his observation: (1) That an increased pulse rate occurring with a cancerous growth, regardless of the locality or size of the growth, is a symptom denoting a bad prognosis; (2) He has noticed that in 85 per cent of cancer cases there is a slightly tender left pelvic colon. The colon is the neglected cesspool of most individuals. Its contents eventually find their way on to the land or into the sea. Is it not a possibility that this method forms the carrier by which our food, animal world, fish, and ourselves become infected? Some day the large intestine will receive as much attention as the mouth. In the hygiene of the colon aperients are useless. The author has found in many cases of obscure ill-health that if the colon is washed out on alternate days with two or three pints of iodine solution, 1 dram to the pint, much of it is readily absorbed and eventually finds its way into the urinary bladder, thus cleansing the lymphatics of the intestine. The improved condition of the patient becomes obvious within two or three weeks. The procedure can be carried out by the patient himself with no special armamentarium other than a douche can and a few feet of rubber tubing. The colon requires the same care as the teeth. The middle portion of the alimentary tract being selective takes care of itself. The small intestine sorts out what is necessary for life. The débris is collected in the large intestine, where if it is not soon evacuated, it undergoes rapid decomposition and lymphatic absorption. It is possible that in this way cancer virus is absorbed, and by a simple method of treatment the lymphatic absorption of the virus may be controlled. Cosens hopes that within another century all human and animal dead bodies will be cremated, and the application of manure to the land will be regulated, as a means of preventing contamination of water and food supplies.

Diathermy Treatment of Nephritis.—In the opinion of R. Gantenberg acute nephritis offers a peculiarly appropriate field for the threefold beneficial action of diathermy, which consists of (1) production of hyperemia and increased capillary circulation of the deep tissues, (2) stimulation of a specific glandular function, and (3) a relaxing effect upon spasms of a smooth muscle organ. In comparison with decapsulation, diathermy presents the advantages of simplicity and complete safety. It is easier to carry out than deep roentgen irradiation, which equally presupposes the use of apparatus and whose action is not without danger of possible sequels. At all events, diathermy as a treatment for acute nephritis deserves more attention and more general use than it apparently has had. The author cites a case of postscarlatinal nephritis with extreme edema in a girl of 15 in whom *x*-rays had produced no effect. Diathermy of both kidneys was prescribed for 15 minutes each day. At first there was no improvement, the intense edema in the surrounding tissues making it difficult to produce hyperemia in view of the weak heart action. After skin drainage of both legs was instituted, however, the effect of the diathermy was startling. Within a week the anasarca had been reduced by 15 liters. The kidney function was promptly reestablished, and albumin and sediment disappeared from the urine in an astonishingly short time. In order to gain increased experience with regard to the influence of diathermy upon kidney function, its effects were studied in a number of persons with healthy kidneys. No difference was found either in the amount or in the specific gravity of the urine after diathermy had been used 15 minutes before the obtaining of the first urine. If, however, in the course of such a test, diathermy was applied at just the time when the maximum excretion was over, it produced a renewed excretion. It is therefore evident that diathermy is capable of increasing urinary excretion also in healthy kidneys. The method has not been found applicable in chronic nephritis, where it has a distinctly inhibiting effect upon excretion. Possibly there is an optimal mean dosage, adherence to which will avoid injury. Further observation in this direction is desirable.—*Deutsche medizinische Wochenschrift,* July 3, 1931.

The Nature of Certain So-Called Essential Hydroceles.—Pierre Cartier, writing in the *Bulletin de l'Académie de Médecine* of June 30, 1931, says that he has carried out studies on 86 hydroceles in 81 patients. The cases were limited to those in which there was no accompanying lesion of epididymis or testicle, and in which it was impossible clinically to determine the pathogenesis of the condition. In every case the liquid was pale yellow, fluidic, and transparent. There was always a fibrinous coagulum, but as a rule this was less abundant than that of hydrarthrosis. There were leucocytes in all but one case, but in none were they very numerous. Erythrocytes were found in 29 per cent of cases,

in one case reaching 14,400 per cu. mm. The bacteriologic findings constitute the interesting part of the author's results. In every case he carefully examined the coagulum for microbes, and found these in 40 per cent. In two cases he identified the gonococcus; in six, the type of diplococcus of which he gave a description in an earlier paper on so-called tabetic arthritis. Twice the liquid contained bacilli which could not be identified. But the most significant point in his findings was the presence in 24 specimens of morphologically recognizable tubercle bacilli (27.9 per cent). Of 24 inoculations made into guinea-pigs only 8 were positive, but the time is past when tuberculization of the guinea-pig need be regarded as necessary in order to establish the tuberculous nature of an acid-resistant bacillus. The presence of tubercle bacilli of low virulence in the content of these hydroceles tends to show that there exist in man very benign forms of surgical tuberculosis which are easily cured. The author inclines to think that such forms are more frequent than statistics indicate. He bases his belief on the fact that in 10 specimens obtained from 5 patients suffering with double hydrocele, only 1 specimen contained bacilli capable of tuberculizing guinea-pigs, all the others remaining sterile. This showed that in one and the same patient the specimen from one hydrocele contained tubercle bacilli while the other contained none. It is impossible to suppose that in such a patient one hydrocele was tuberculous and the other not. Rather must it be assumed that in one of the hydroceles the bacilli were so few that they eluded examination, or else that the pathogenic agent was present in such a form that it was not recognizable morphologically. It seems probable that a considerable number of these hydroceles are due to non-microbic forms of tuberculosis, and that many other surgical serous effusions are due to the same cause.

The Treatment of Habitual Abortion with Wheat-Germ Oil (Vitamin E).—P. Vogt-Möller, writing in *The Lancet*, July 25, 1931, ccxxi, 5630, states that as yet the importance of vitamin E to the organism has been elucidated only in rats and mice. It has been shown that the sterility occurring when this vitamin is lacking is of different pathogenesis in the two sexes. In the male it seems to play a part in spermatogenesis, its lack resulting in more or less marked degeneration or even complete disappearance of the spermatogonia. In the female on food free from vitamin E, ovulation and implantation take place normally, but the implanted ova are reabsorbed at an early stage of the pregnancy. Having confirmed these findings of Evans and Burr, Vogt-Möller succeeded in obtaining favorable results in the treatment of sterility in cows with wheat-germ oil. He then applied the treatment to habitual abortion in women. The first patient, a woman 24 years of age, had aborted four times after absence of menstruation for seven or eight weeks. She came under treatment six weeks after the last menstruation, when a diagnosis of pregnancy was made and confirmed by the Zondek-Aschheim reaction. Treatment with wheat-germ by mouth was instituted, 5 c.c. being given once daily during the first fortnight, then the same dose every second day for a fortnight, and then 5 c.c. every sixth day. The patient went through pregnancy and was delivered of a healthy girl. The second patient, aged 25 years, had aborted five times in the third or fourth month. Under the same treatment she went to term and gave birth to a healthy infant. Both patients tolerated the treatment well. The diet of these women had not differed from the ordinary food taken in Denmark, so that it could scarcely have been poor in vitamin E, but possibly the need of this vitamin varies in different individuals, so that a hypovitaminosis E may have been present in these two patients. While the material is too scanty to allow of any decisive statement, it suggests that vitamin E may be of therapeutic value in the treatment of habitual abortion.

Diabetic Coma with Unusual Complications.—It is well known, says Giuseppe Pellegrini, in the *Riforma medica* of June 8, 1931, that diabetic coma may be a complication of a true renal insufficiency, which may give to the entire picture the appearance of a uremic coma; and also that at other times evident signs of hepatic insufficiency may be observed in diabetic coma, of which the characteristic feature is the absence of ketogenesis with a marked reduction of the alkaline reserve. In the author's case, diabetes mellitus was accompanied by severe changes in the liver, and at the time of death the coma supervening was of a complex nature. There existed an hepatic lesion of long duration, probably of alcoholic origin, and there could be no doubt that the gravity of the case was partly the expression of this; but it is probable that in addition an hepatic factor had combined with a pancreatic factor to produce glycemia and acidosis. Hence it was practically inevitable that there should be a coincidence of edema and of icterus, of aggravation of the latter, accentuation of the oliguria, and a simultaneous appearance of coma. In the final picture the hepatic factor seemed to predominate. The explanation of the case seems to be as follows: The complete absence of any clinical signs of degenerative or inflammatory lesions of the kidneys leaves a doubt as to the possibility of such lesions. One may therefore take the view, though with some reserve, that the diminished renal capacity for eliminating water is comparable to the similar behavior that often takes place in connection with diuresis in cirrhous and hepatic cases. Such changes of renal function are generally attrib-

uted to portal hypertension, of which the ascites would be the expression; but it has already been demonstrated that such retention is not a disturbance of the circulation but rather a functional insufficiency of the liver, which has an influence upon the functioning of the kidney. Thus it is clearly possible for hepatic factors to interfere in diabetic coma, and to impress upon the syndrome a particular clinical character and course which differentiate it evidently from a diabetic coma that is due purely to acidosis, and also from diabetic coma with a nephritic complication.

Present Status of the Classification, Pathology, and Etiology of Chronic Rheumatic Disease.—Joseph L. Miller finds that much of the literature on chronic arthritis is unintelligible on account of the failure to specify the particular type of disease under discussion. Very frequently no attempt is made to differentiate the two types. At the recent congress at Liége it was decided that at least for statistical purposes a uniform nomenclature should be adopted for English, German, and French writers. In English the two terms recommended were rheumatoid arthritis (infective periarthritis) and osteoarthritis. Some of the terms which have been used synonymously with rheumatoid arthritis are atrophic arthritis, chronic infective arthritis, and arthritis deformans. Hypertrophic arthritis is synonymous with osteoarthritis. Pathologically, the joint changes in rheumatoid arthritis are inflammatory; in osteoarthritis degenerative. Etiologically, rheumatoid arthritis is usually and probably always due to infection. Etiologically trauma, in the broad sense of the word, is the chief, if not the sole, factor in osteoarthritis of the extremities. It is probably the most frequent factor in osteoarthritis of the spine. Here, however, the pathologic changes are quite different from those observed in the extremities, and the possible rôle of infection in certain types cannot be ruled out. There appear to be several types of lesions in osteoarthritis of the spine. By far the most frequent form is the so-called senile type, which shows an increasing incidence with years, though it may develop at any age following acute trauma. A second type of change may be seen in osteomyelitis of the vertebra. The cartilage here is usually destroyed. It is yet to be determined whether infection is responsible for the growth of osteophytes, or whether they arise as a direct response to infection. The "poker spine" has a different pathology. Here the cartilage is destroyed and replaced by bone, giving rise to a perfectly rigid spine. It is thought that these changes are directly due to infection. The presence of both rheumatoid and osteoarthritis in the same individual has been a stumbling block to everyone who has attempted to classify chronic arthritis. Many of these mixed forms may be explained if we accept acute trauma, long-continued mild trauma, age, and strain as etiological factors in osteoarthritis. The presence of osteoarthritis in combination with the rheumatoid types does not necessarily mean that the osteophytes are directly due to infection. Rheumatoid arthritis at any age may have been preceded by a localized osteoarthritis from acute trauma. For the non-infective type "osteoarthrosis" is a more fitting term that "osteoarthritis." *American Journal of the Medical Sciences,* August, 1931, clxxxii, 2.

Two Cases of Prolonged Regular Tachycardia.—From a clinical point of view, says L. Langeron in the *Archives des maladies du coeur, des vaisseaux et du sang* of May, 1931, tachycardia may be classified as regular or irregular, according as the intervals between cardiac contractions with accelerated rhythm are the one or the other. Either type may be permanent or paroxysmal, according as the acceleration of rhythm apears as a persistent phenomenon or merely as an episode. The two bases of classification are relatively independent. From a physiopathologic point of view, regular tachycardias are characterized by the appearance of a normal sinus rhythm or of another rhythm of an auricular, auriculoventricular, or ventricular nature. Irregular tachycardia is due to auricular fibrillation or to fibrillo-flutter; extrasystoles may occur, according as there is an association of a tachycardia that is now regular, now irregular. Not all types of tachycardia, however, lend themselves to schematization of this kind. There are abnormal and exceptional cases, and it is for this reason that these two personal observations are published with their electrocardiograms. In the first, a youth of 17 with various malformations, including scoliosis and spina bifida occulta, had a prolonged regular tachycardia of 200 per minute, which had resulted in an enormous cardiac hypertrophy and in slight signs of insufficiency. The tachycardia, which was presumably of an auriculoventricular nature, was reduced gradually by means of digitalin and pilocarpine. The second case, in a young man of 20, was one of regular tachycardia accompanied by palpitation, with cardiac hypertrophy but without insufficiency. The condition was of recent appearance at a definite time, and the pathologic rhythm was now habitual, with the normal rhythm the exception. This condition too yielded to digitalin and pilocarpine treatment. There were alternations of pseudobradycardia with polymorphism of complexes and of normal rhythm. The pulse exhibited a very unstable character of reduction of rhythm. The initial pathologic rhythm was of an auriculoventricular nature. These cases show a certain similarity, but in the first the rhythm remained identical during the phase of restoration, while in the second there appeared instead contractions of a polymorphous nature. The cure was more stable

in the first than in the second Both serve as examples of a transition between permanent regular tachycardia and paroxysmal tachycardia In both the value of digitalin-pilocarpine treatment was alike demonstrated

Heart Disease and Pregnancy—Following the plan of Standen, Duncan and Sisson, Cecil Young classifies pregnant cardiac patients into four groups: (1) Cardiac neuroses, (2) doubtful heart disease, (3) rheumatic valvular disease, (4) serious heart disease Patients of the first two groups can be depended upon to go through pregnancy with no ill effect on the heart They need reassuring more than anything else, if they can be convinced that their symptoms are purely functional they do very well Rheumatic valvular disease of the heart without enlargement of the organ or any history or sign of heart failure, need not be greatly feared Aortic regurgitation, even without enlargement of the heart, is a trifle more serious In the fourth group are placed all cases of serious heart disease, such as frank mitral stenosis or aortic regurgitation with definite gross enlargement of the heart, myocardial degenerations congestive failure, and auricular fibrillation In the management of these conditions every case should be assessed on its own merits In mitral stenosis, if the response to effort is good, the patient may be allowed to proceed to term, but with poor response to effort and in the other types of cases of this group, except in the actual presence of heart failure, therapeutic abortion is the safest procedure Other types of cardiac disease in which pregnancy is obviously contraindicated are acute myocardial disease, thyroid hearts, specific heart disease, paroxysmal tachycardia and coronary disease In acute hyperthyroidism it is extremely dangerous to interfere with pregnancy The hyperthyroidism should be treated first, taking a chance on dealing with the pregnancy later In cases belonging to the first three groups the only precautions necessary are careful supervision in order to avoid undue strain and the institution of hygienic measures In cases of serious heart disease, interruption of the pregnancy should be advised prior to the fourth month After the fourth month it is safer to wait for a few months, provided the patient's condition will permit Induction of labor mechanically or by other means at the thirty-sixth week is usually a rational and comparatively safe procedure In the fifth and sixth months cesarean section may be done as an emergency measure During the waiting period the cardiac reserve should be built up In the actual management of labor, ether is the most satisfactory anesthetic during the second stage Preparation should be made for all emergencies The patient should be digitalized before labor, oxygen, intravenous saline, a venesection outfit and loaded syringes should be available As soon as the head is on the perineum, an episiotomy should be done and forceps applied The actual delivery of the child should not be too hurried Morphine and atropine are useful after the placenta has been expelled The patient should be kept in bed under careful observation for a month after labor Many women with apparently severely diseased hearts come through repeated pregnancies with very little additional damage.—*Canadian Medical Association Journal*, August, 1931, xxv, 2

Circumscribed Scleroderma—Writing in the *Riforma medica* of June 15 1931, Gino Murero discusses the pathogenesis and etiology of circumscribed scleroderma There has been a tendency of late to regard the origin of this disease as an exclusively endocrine problem Its greater frequency in women than in men may be attributed to the instability and the greater importance of the sexual function in the former In women scleroderma develops nearly always at an advanced age with reference to ovarian function (menopause, hysterectomy, or ovarian tumors) or else in the years of early youth preceding menstruation There are not yet sufficient data to confirm the genital element as a fundamental etiological factor, but the earlier interpretation based exclusively on thyroid dysfunction cannot be supported It is worth while to investigate the theory that a dysfunction affecting all the principal endocrine glands in their complex synergetic activity leads to a functional dystonia of the scleroderma victim, of a constant, uniform and accentuated character In the author's case the affection appeared on the neck, abdomen, and both arms of a girl of 16 who had never menstruated, and who had been suffering for 4 years with articular rheumatism, from which she had been free only 2 months when the scleroderma began Thyroid preparations were unavailing, but after about 1 month of ovarian treatment menstruation made its appearance—at first scanty and irregular, but well established after 8 months of treatment During this period no new spots appeared The large spot on the abdomen showed a tendency to heal, while those on the neck and arms became stationary with no tendency to spread The author concludes that the articular rheumatism might well be an etiological element in this case, and that it found a subject well adapted for its development by reason of her condition of hypo-ovarism The correlation of the endocrine glands is so intricate that endocrine treatment must not be understood as a true causal therapy for scleroderma but solely as a corrective treatment for that trophoneurotic state which lies at the bottom of the process In view of the relations existing between sympathetic and glandular function we must not forget that in many cases the endocrine factor plays a secondary role

LEGAL

A DANGEROUS PRECEDENT

By LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

It has long been one of the fundamentals of our system of law and government that an attorney is an officer of the Court. Logically it would seem to follow that the Court should have the inherent power to deal with the admission and disbarment of lawyers. In this State there is no question that the Courts have such power. They not only possess the power, but time and again they have exercised it to disbar, suspend or reprimand attorneys for acts clearly demonstrating the unfitness of a particular individual to remain in a learned and honorable profession. This power is, of course, wholly apart from the statutory provision automatically disbarring an attorney convicted of a felony.

In the City of New York a few years ago the Bar Association conducted an inquiry, colloquially known as "the ambulance-chasing investigation." The result of such investigation was that the Appellate Division disbarred, suspended or reprimanded a large number of attorneys. The investigation was welcomed by all honorable members of the Bar and resulted not only in expelling a large number of unfit from the profession, but served as well as an effective deterrent to those who might be inclined to transgress against the rules of ethics. Both logic and common hense dictate that the Bench should have inherent power over the conduct of the Bar. The right to practice law in this State is a license extended to those who have met the necessary qualifications for admission to the Bar, and subject at all times to be revoked when the holder thereof has demonstrated his unfitness to remain in the profession.

These observations are preliminary to a discussion of a very curious and extraordinary situation that has arisen in one of our Western States. A so-called ambulance-chasing investigation was recently conducted there and proceedings were taken to disbar a certain lawyer. The order of the Court, after his case had been thoroughly investigated, was that he should be suspended from the practice of law for a certain period of time "and for such period thereafter as shall expire before his license to practice law is restored and he is reinstated a member of the Bar by this Court, upon the presentation of proof that the expenses of this proceeding have been paid, and upon the further condition that he shall before being reinstated, satisfy the Court both by his conduct from this time forward and by assurances then given the Court that he will not, if reinstated, be guilty of such conduct as that involved in the charges made in the complaint in this action."

In the opinion rendered by the Court in this case the Court commented on its own power to discipline attorneys, stating in part as follows:

"The power to protect Courts and the public from the official ministration of persons unfit for practice in them, was fully established in the former decision of the Court in this case, where it was held that when the people by means of the constitution established Courts, they became endowed with all judicial powers essential to carry out the judicial functions delegated to them. The Courts established by the constitution have the powers which are incidental to or which inhere in judicial bodies, unless those powers are expressly limited by the constitution. But the constitution makes no attempt to catalogue the powers granted. It is the groundwork upon which the superstructure of government is raised by the exercise of those powers which are essential to carry out the functions imposed upon each department of government. These powers are known as incidental, implied, or inherent powers, all of which terms are used to describe those powers which must necessarily be used by the various departments of government in order that they may efficiently perform the functions imposed upon them by the people."

The Court continued:

" . . . the courts are not powerless in the absence of legislative tests of eligibility, to protect themselves, and the people whom they serve, from those members of the Bar whose conduct has been such as to forfeit their right to longer act as ministers of justice in the Courts. 'It is well settled that a Court authorized to admit an attorney has inherent jurisdiction to suspend or disbar him for sufficient cause, and that such jurisdiction does not necessarily depend on any express constitutional provision or statutory enactment.' "

Subsequent to this lawyer's suspension and prior to the time within which he could petition the Court for reinstatement pursuant to the provisions of the order suspending him, a bill was introduced in the State Legislature for the sole purpose of readmitting him to practice and restoring to him all the rights to practice as a member of the Bar. The bill was passed. It came be-

fore the Governor for veto or approval. The Governor refused to veto the bill. In approving the bill, the Governor wrote a long memorandum in which he argued that neither the constitution of the State in question nor of the United States limited the power of the Legislature to regulate admission to the legal profession. He also held that the Legislature possessed the power to reinstate this lawyer despite the fact that he had been disbarred by the order of the Court.

The anomalous situation created by the approval of this bill admitting the man to practice who had been previously disbarred by the Court and never reinstated by it, is clearly shown in the events transpiring subsequent to the approval of the bill. What happened thereafter, as reported by the *American Bar Association Journal* was as follows:

"Passage of the legislative act was soon followed by efforts on the part of Mr. A. to secure recognition of his status as an attorney by the Courts. According to one newspaper, 'two circuit judges, B and C, have acknowledged his status by signing legal papers in which he appeared as attorney. Circuit Judge D has refused to sign any of A's papers and Circuit Judge E has refused to recognize him in open court.'

"On the refusal of Judge E to recognize Mr. A, the latter asserted the Court was prejudiced, and was instructed to file affidavits to that effect if held that opinion. The case was thereafter scheduled for a hearing before Judge F. The first matter taken up in the proceeding was the motion of opposing counsel to quash the summons, on the ground that Mr. A is not entitled to practice. Mr. G, who made the motion, pointed out that it was for the purpose of testing the constitutionality of the claim of the legislative act that the Legislature rather than the Supreme Court has the power to control admission to the practice of the law. The Court stated that the motion required much research and that he preferred that some one else hear it as he was already behind in his calendar due to the illness and death of his mother. Judge H. was thereupon requested to act and consented to do so. He held a hearing later, at which counsel presented arguments, and took the matter under advisement. When this was written his decision had not been announced."

Happily, such a situation could not arise in our State. Many years ago one of our Courts said:

"The general power over attorneys is . . . confined to or exclusive in the Supreme Court. It is through that Court that they obtain admission and it is by that Court they can be disbarred, or reached for any general misconduct, not immediately connected with actions or proceedings pending in other Courts."

Wholly apart from the question as to whether or not, under the constitution of the particular State in which this question arose, the Governor was correct in approving the bill, it seems to us most unfortunate that such a bill was introduced. A lawyer is an officer of the Court. In this case the Court in question had suspended the lawyer after a full hearing on the merits, but if by legislative enactment an attorney may nullify the action of the Court, it means, of course, that the Courts have no control over their own officers.

The precedent is an extremely dangerous one. For example, a physician whose license was revoked for fraudulent practices after a full hearing might, under the ruling in question, secure the passage of a bill reinstating him to practice although he has clearly demonstrated his unfitness to remain a member of the great healing art. Special legislation providing privileges and immunities to individuals who have proven themselves unable or unwilling to comply with established professional standards tis vicious in principle, is contrary to public policy and works a hardship not only upon the honorable members of the profession but upon the public as well.

ALLEGED NEGLIGENT REMOVAL OF UVULA DURING TONSILLECTOMY

In this case a young colored man consulted the defendant, a physician specializing in general surgery, with respect to the condition of his tonsils. On examination they were found to be diseased and hypertrophied. The doctor suggested their removal and the patient returned a few days later and in the doctor's office, under a local anesthesia of novocaine the tonsils were removed by the snare method. There was very little hemorrhage and the operation was uneventful. The patient was able to leave the office about three hours subsequent to the operation.

The patient saw the doctor on several occasions thereafter and at the time of his last visit to the defendant complained that the doctor had cut something out of his throat which he would not have removed. The doctor on examination found that the novocaine had caused the end of the uvula to slough, but that no harm had been done to the organ.

The next that the doctor heard of the matter was when a summons was served on behalf of the patient, commencing an action for damages based on alleged negligence which caused injury to the uvula. When the case came up for trial, the defendant was ready with his witnesses to defend the action. The plaintiff's attorney submitted to the court an affidavit to the effect that he was unable to locate his client. A motion was made to dismiss the case for the plaintiff's failure to appear which was granted, finally closing the matter in favor of the doctor.

NEWS NOTES

JOINT COMMITTEE ON THE GOVERNOR'S HEALTH COMMISSION

Two standing committees of the Medical Society of the State of New York, the Committee on Public Relations and that on Public Health and Medical Education, were instructed by the House of Delegates, on June 1, 1931, "to study the report of the Governor's (Health) Commission, and to make recommendations upon all or any of the subjects presented; and that the said Committee report its recommendations to the House of Delegates, not later than January 1, 1932; and that the Council, in its wisdom, refer this (report) to the House of Delegates, either by a special meeting or by referendum of the House." (See this Journal, July 1, 1931, page 828.)

This Joint Committee on the Governor's Health Commission met in the rooms of the State Medical Society, 100 State Street, Albany, New York, on Friday, September 11, 1931, there being present: Dr. T. P. Farmer, Syracuse, Dr. M. B. Tinker, Ithaca; Dr. E. G. Whipple, Rochester; Dr. M. H. Atkinson, Catskill; Dr. W. A. Groat, Syracuse; Dr. J. E. Sadlier, Poughkeepsie; Dr. A. J. Hambrook, Troy. Dr. O. W. H. Mitchell, Syracuse.

There were also present: Dr. W. D. Johnson, Batavia, President of the Medical Society of the State of New York; Dr. J. S. Lawrence, Executive Officer, and Dr. Frank Overton, Executive Editor.

The Joint Committee formally organized by electing Dr. T. P. Farmer, Chairman, and Dr. J. S. Lawrence, Secretary.

The Committee discussed the scope of its work, and decided that it would first consider the Preliminary report of the Governor's Health Commission, which was issued on February 16, 1931. The recommendations contained in this report were printed in the NEW YORK STATE JOURNAL OF MEDICINE of February 15, 1931, page 230.

It was reported that the following provisions were enacted into law during the Spring:

1. The construction of three tuberculosis hospitals by the State.
2. Provision for the treatment of venereal diseases at public expense.
3. Divisions of cancer control and orthopedics be established in the State Department of Health.

The recommendation for the compulsory establishment of a department of health in every county failed to be adopted by the Legislature, but a similar bill will probably be introduced in the next Legislature.

The Joint Committee expressed its desire that every county society should express the opinion of its members in regard to each of the recommendations of the Governor's Health Commission. The full report is printed in this Journal in order that every member may have the opportunity to act intelligently upon its recommendations.

PRELIMINARY REPORT OF THE GOVERNOR'S SPECIAL HEALTH COMMISSION

1. LETTER OF TRANSMISSION

February 16, 1931.

His Excellency
THE HONORABLE FRANKLIN D. ROOSEVELT
Governor of the State of New York

SIR.—The Special Health Commission, appointed by you on May 1, 1930, has the honor to submit herewith a preliminary report in which is contained a summary of what the Commission believes to be important health problems requiring legislative action before any real progress can be made toward their solution.

Your favorable consideration is urged for the recommendations presented herein, and their submission to the legislature for action during the present session.

In addition to the topics requiring legislative action which are presented in this preliminary report, the Commission has embraced within its deliberations studies of a number of equally important subjects, and will present a final report later in the year covering the whole field of its study.

Respectfully submitted,

Livingston Farrand, *Chairman.*
George W. Cottis
Simon Flexner
Homer Folks
Edward L. Keyes
John A. Kingsbury
Agnes Leach
Henry Morgenthau
Matthias Nicoll, Jr.
John M. O'Hanlon
Thomas Parran, Jr.
William H. Ross
Katharine Tucker
Linsly R. Williams.

2. SUMMARY OF HEALTH PROBLEMS, 1931

The Commission finds that the pressing immediate needs are:

(1) Effective local health departments with qualified personnel;

(2) More effective service in the control of tuberculosis, cancer and the venereal diseases;

(3) More comprehensive measures to reduce infant deaths and deaths among mothers from causes incident to childbirth;

(4) Further coordination of school hygiene with other health services,

(5) Better organization for the discovery and cure, rehabilitation and care of crippled children;

(6) The extension of public health nursing throughout the state to reach the standards now in effect in a few areas;

(7) Protection of the public health through additional safeguards in the purification of water supplies and the prevention of stream pollution;

(8) More attention to the growing problem of industrial hygiene.

The most outstanding of these needs without which results in these and in all aspects of public health cannot be secured, is a reorganization of the whole system of local health service on a county rather than the town and village basis, with provision for qualified personnel, both in counties and cities.

3. MAJOR RECOMMENDATIONS

1. *County Board of Health.* That county boards of health be organized in all counties to provide for the rural areas and villages more effective control of tuberculosis, the venereal diseases, and other communicable diseases; protection of maternity and infancy; safeguarding of public milk and water supplies; more effective public health nursing service, and other elements of a modern public health program.

2. *Local Health Administration.* That in cities of more than 50,000 population and in the large counties, health commissioners hereafter appointed be required to devote their entire time to the duties of their office.

3. *Tuberculosis.* That the state establish three additional state tuberculosis sanatoria, primarily to receive patients from counties which are too small in population and wealth to maintain suitable sanatoria, the counties reimbursing the state for maintenance of their patients; that the administration of the State Sanatorium at Ray Brook be placed under the Department of Health, and that provision be made for early diagnosis and more effective home supervision and assistance of tuberculous patients through county health departments.

4. *Venereal Diseases.* That provision be made for the diagnosis and treatment of the venereal diseases as a public health problem.

5. *Cancer.* That a division of cancer control be established in the Department of Health.

6. *Maternity, Infancy and Child Hygiene.* That adequate measures for protecting the health of mothers and children be included in the program of every city and county health department.

7. *Public Health Nursing.* That public health nursing service be extended, particularly in the rural areas, as an integral part of the program of county health departments.

8. *Crippled Children.* That the administration of the State Reconstruction Home at West Haverstraw be placed under the Department of Health, and that state and local services be extended for the discovery and care of crippled children.

9. *Industrial Hygiene.* That the inspection of certain industrial establishments in villages and towns be performed by the Department of Labor instead of by local health officers.

10. *Public Water Supplies.* That the approval of plans for proposed new and extensions of existing public water supplies, in so far as the sanitary quality is concerned, be vested in the Department of Health.

11. *Stream Pollution.* That the pollution of streams by industrial wastes dangerous to the public health be regulated in the same manner as pollution of streams by sewage.

12. *Public Health Personnel.* That the present authority of the Public Health Council to establish qualifications for certain public health personnel be extended to include other positions in the public health field.

4. INTRODUCTION

The Commission was asked to study and report to the Governor upon the administrative and legislative aspects of public health in New York State. It was requested to take into consideration the activities of state and local health authorities and their relations one to another; the recent progress in public health in other states and abroad; and to examine the extent to which the needs of the people of the state were being met in the vital field of public health, in order that scientific knowledge may be utilized more fully for the prevention of disease.

The Commission has carried on its investigations in accordance with this request. Information on many special features of health service has been gathered from abroad and from other states by personal visits of Commission members and by examination of official records and reports. In particular, the division of responsibility between state and local health authorities, and their relation to the medical profession and to the volunteer health associations throughout the state has been given careful study.

The Commission has been fortunate in having available for its consideration also the recent reports from the White House Conference on Child Health and Protection, which represent a complete statement of the status and needs in child health throughout the country. In the Commission report covering this field, the conclusions and recommendations are in harmony with the national findings, adapting them to fit the specific needs of New York State. An example is the fundamental recommendation that the whole system of rural health service in the state be reorganized on a county basis to replace the present inadequate town and village system.

After outlining the scope of its work, subjects were assigned on a topical basis to the fourteen members of the Commission, each of whom served as chairman of one or more committees for the study of a specific public health problem. With each such committee was associated a group of persons having special knowledge of the particular subject. In all, a total of eighty-six persons thus participated directly in the work of the Commission, and an even larger number contributed indirectly by furnishing valuable information and assistance. The facilities of the Department of Health have been utilized by the Commission, and a number of other state departments together with a large group of cooperating organizations have contributed to the value of the studies.

Inasmuch as the administration of public health in New York City is entirely separate from that of the rest of the state and as many of the health problems of that city are peculiar to it, the Commission after consideration determined to exclude from its deliberations and recommendations matters concerned with health administration in New York City, as did the Commission of 1913.

That New York State is in an enviable position among the forty-eight states in the standing of its health work is due in large measure to the revision of the Public Health Law made by legislative enactments in 1913. This vital legal revision was grounded upon the recommendations of a State Health Commission of which the late Dr. Hermann M. Biggs was chairman.

The major recommendations of the Commission of 1913 were the following:

> The creation of a Public Health Council with authority to enact sanitary regulations; security of tenure of office and satisfactory compensation for the State Health Commissioner to secure the most efficient man for that position; state supervision over local health officers and the enforcement of the public health law; division of the state into sanitary districts; increased salaries and added duties for local health officers; more efficient birth and death registration; authority for employment of local public health nurses; more complete reporting and supervision of tuberculosis; provision of county tuberculosis sanatoria and additional state provision for incipient cases; creation of bureaus of child hygiene and public health nursing in the Department of Health; adequate laboratory facilities readily available for all local health authorities; regulation of midwifery; extension of health education work; and encouragement of courses in sanitary science in educational institutions.

Almost all of these recommendations have been translated into law and practice, and have resulted in many improvements in the extent and quality of health service to the people of the state. This is particularly true of the organization of the Department of Health on an efficient basis.

Eighteen years' additional experience, however, has shown that to carry into effect a modern health program dealing with such vital problems as tuberculosis, the venereal diseases, public health nursing, and maternity and infant hygiene, further steps are necessary, and that for this purpose the town and village is too small an administrative unit in point of view of population and wealth.

In addition to the topics which are presented in this preliminary report, the Commission has embraced within its deliberations studies of the important subjects of: Mental Hygiene, Medical Care, Control of Communicable Diseases, Laboratory Service, Dental Hygiene and Public Health Education. The Commission is formulating a series of administrative recommendations in regard to many of these problems. There is no pressing need at this time, however, for legislative action on these subjects, and they are, therefore, excluded from this preliminary report.

5. PRESENT STATUS OF THE PUBLIC HEALTH

Public Health in New York State compares very favorably with that of other states in the marked improvement which has occurred in recent years.

In 1900 the expected span of human life was forty-seven years. By 1930 the span of life was increased to fifty-seven years. In 1913 the death rate in the state for all communicable diseases was 419.3 per 100,000 population; in 1930 it was 196.4. Tuberculosis mortality has declined more than one-half since 1913; and the general death rate has declined 14 per cent during the same period. Typhoid fever, once very prevalent, is now a rare disease. Diphtheria has declined about two-thirds since 1913. Infant mortality likewise has been reduced 50 per cent.

If the death rates of 1913 from these several causes had continued to prevail, there would have been in 1930, 43,478 more deaths from all causes; of children under one year of age now living 10,961 would have died; 12,304 additional deaths from tuberculosis, 1,184 from typhoid fever, and 2,091 from diphtheria would have occurred in New York State.

In addition to the measurable direct benefits from these lower death rates there has been an even larger reduction in sickness from preventable causes and from their many complications and end results. These indirect benefits in improved health, while not accurately measurable, have none the less added to individual efficiency and prevented the economic waste of sickness among the citizens of the state.

This notable progress in the prevention of sickness and of death has been due to a variety of factors. A greater knowledge of the causes, and consequently the cure or prevention of disease, a better quality of medical service, the general education of the public in matters of health, the improvement in standards of living, as well as more efficient health administration, all have contributed.

What has been done in the improvement of public health is only a small part of what can be done if available knowledge were translated into concerted action for the prevention of sickness and death throughout the state.

Through improved individual and community care it is possible again to cut in half the death rate among babies. Through further improvement in water and milk supplies, and the control of typhoid carriers, typhoid fever should disappear entirely. Diphtheria can be marked off the list as a cause of death if all babies are protected by toxin-antitoxin. Tuberculosis is still the most frequent cause of death between the ages of twenty and forty. Here the death rate can be cut in half once more by the earlier diagnosis and better care of patients, and by general measures to improve the individual health. There are far too many deaths of mothers during childbirth, when better medical and nursing care would reduce materially this needless loss of life.

Among the diseases in which less progress has been made, syphilis, with its many and serious end results, continues almost unabated as a major health problem, yet syphilis is one of the few diseases which can be wiped out completely if well known methods for the discovery and treatment of cases were used everywhere. Cancer now ranks second only to heart disease as the most frequent cause of death. It can be cured in many cases if recognized earlier and properly treated.

Even in the fields where the gains have been greatest, accomplishment has been uneven in the different localities of the state. Any further progress will depend upon strengthening the weak links in the chain by the establishment of a satisfactory system of local health administration.

6. THE STATE HEALTH ORGANIZATION

The Commission believes that in the organization and functioning of its Department of Health, New York stands second to no other state in the Union. In face, the state itself has been obliged to assume a larger measure of responsibility and to develop a more extensive organization than would have been necessary except for the inadequacy of local health machinery.

Public Health Council. One of the most far-reaching results of the work of the Commission of 1913 was the creation of the Public Health Council, having no executive or administrative function but authorized to enact a sanitary code dealing with the security of life and health in the state and having the force and effect of law. The value of this flexible health code has been amply demonstrated. Through its authority to prescribe qualifications for certain personnel the Council has had great influence in promoting uniformity and in improving the standards of health service.

The support of successive state administrations and legislatures has made possible the development of many highly efficient health department services. The salaries

of the major professional and technical personnel in the Department of Health, however have not kept pace with positions of comparable responsibility in other state departments and with salaries for similar positions in other states Deplorable also is the lack of a compensation policy for this personnel

The Commission makes no specific recommendation at this time regarding salaries but desires to call attention to this situation which menaces the standards of the department

State Health Activities The activities of the Department of Health have been the subject of critical scrutiny and detailed analysis and will be discussed in the final report

The Commission has no recommendation for any major change in the essential structure or policies of the State Department of Health itself

State and Local Responsibility Consideration has been given by the Commission to the future logical division of responsibility between the state and local authorities Certain health problems particularly those of a statewide character, and those which require highly technical training must be handled by the state In the rural districts experience has shown also that it is necessary for the state to stimulate the development of modern health service through professional advice and financial aid Throughout the report it is recommended that the local authorities assume all responsibility for public health which they can handle for the major part of the direct health service to the people is primarily a local responsibility and should be rendered by the communities themselves

Careful consideration has been given by the Commission to the policy of state aid in public health which has been in operation for ten years The conclusion has been reached that state aid is a necessary policy particularly in the rural areas and in the development of new health activities Sound precedent for it is to be found in other phases of community welfare. In fact the Commission is of the opinion that the only alternative of state aid for rural health service is operation by the state itself of direct health services to the people Those who believe that state aid is undesirable must concede that its inevitable alternative is even less desirable

Under the present conservative policies of granting state aid for local laboratories for the rehabilitation of handicapped children, for county nursing services county health departments, county general hospitals in rural areas and similar health services much has been accomplished in promoting the public health which would not otherwise have been done.

The Commission recommends therefore, that state aid be continued for the development and operation of local health activities

7 LOCAL HEALTH ORGANIZATION

The primary responsibility for health protection always has been vested in cities villages and towns In recent years, however, permissive laws have been passed which enable counties to create boards of health and to conduct health services which obviously were possible only on a county basis

Present Local Organization There are now in the state 1 099 local health jurisdictions consisting of four county 59 city 293 village, 597 town and 146 consolidated (village and town), boards or departments of health Excluding county and city health units there is a total of 1 036 local health units, with a population ranging from a few hundred to a few thousand persons In towns the town boards and in villages the trustees constitute the boards of health These boards appoint a physician as local health officer at an annual salary of not less than 15 cents per capita amounting usually to from $150 to $200 per year

Present System Inadequate Designed to meet conditions of 1850, the present system of town, village and small city boards of health fails utterly to meet needs of 1931 because these units of population are too small to provide the services which modern public health demands Public health as a science had its origin, and has had its remarkable development since these local boards of health were established Advances which have been made in laboratories and research centers throughout the world in knowledge of the methods for the prevention of disease necessitate the employment for this purpose of trained personnel who will devote their entire time to protecting community health In the modern health program, qualified health officers nurses, engineers laboratory directors, and other professional personnel are essential if satisfactory service is to be expected Moreover, better methods of communication by reason of the telephone improved highways, and the automobile make it easier to serve the larger territory of a county than it was to serve a single town a half century ago

Present County wide Health Services The recognition of the fact that the individual town and village is too small a government unit to support economically many health services has led in recent years to the general development on a county basis of several highly important services, such as tuberculosis prevention public health nursing and laboratory activities In four counties county boards of health have been organized which are providing for the people a much more effective service than is secured in the other counties In each of these four counties the work of the county health departments has been very satisfactory

Need for County Health Unit The present system of town and village boards of health, upon which there are usually superimposed a number of county services for public health results in a confusion of responsibility lack of coordination, waste of effort and excessive costs for the services rendered The imperative need therefore is to seek out the most effective governmental units and impose upon them the needed powers and full responsibilities The county is the only available unit for this purpose. In New York State county boards of health have been endorsed by the State Medical Society the State Sanitary Officers' Association and many other organizations interested in public health That the county with full time personnel is recognized as the best possible unit for satisfactory local health administration is evidenced also by the active sponsorship of the United States Public Health Service, and by the fact that there are now in 35 states more than 500 county health departments some of which have been in successful operation nearly 20 years *The Commission feels that this is the most vital matter it has had to consider and urges that legislation be enacted substituting the county as the unit of local health administration in place of the town and village*

8 ADVANTAGES OF COUNTY HEALTH UNIT

1 The unit of population is sufficiently large to permit the employment of trained personnel

2 One responsible board will be substituted for the many town and village boards of health, the county nursing committee county milk inspection committee county clinic committees and boards of managers of county laboratories

3 A plan of continuing health service can be developed for the whole county and all the health personnel can be mobilized to meet emergency conditions in any part of the county

4 Duplication and overlapping of effort which now exist will be prevented and better health protection can be furnished for present expenditures

5. The relative needs for various types of health service in the county can be determined and available public funds allotted in proportion to these needs.

6. School nursing activities now lacking in many rural schools can be furnished by nurses employed by the county board of health.

7. If school medical inspection is made a function of county boards of health, this important activity can be conducted more efficiently on a county-wide basis with trained personnel than under the present system.

8. Through the permissive provision under which tuberculosis control activities may be administered by the county board of health, this activity can be directly coordinated with other health services. This is particularly desirable in the smaller counties.

9. Under the permission granted to cities to join the rest of the county for purposes of health administration, further coordination of health work on a county-wide basis is made possible. Such a union is desirable for cities of less than 50,000 population.

10. New and much needed health activities can be undertaken which are not now carried out and not possible under the present system.

11. Vitally important maternity and infant hygiene measures can be organized and efficiently conducted.

12. Treatment facilities for the control of the venereal diseases can be provided.

13. The sanitary quality of milk can be assured through a county-wide inspection service.

14. The sanitary quality of water supplies can be supervised through a county sanitary engineer.

15. Modern epidemiological methods can be applied for control of the communicable diseases in place of the present ineffective system. Toxin-antitoxin, smallpox vaccination and other activities can be conducted by personnel provided for these and other services.

16. Less intimate state supervision and fewer direct services from the Health Department will be required because of the better local organization.

9. RECOMMENDATIONS

1. That county boards of health be appointed in all membership of the county board of health.

2. That the county health commissioner devote his entire time to the duties of his office in counties having a population under the jurisdiction of the board of health of more than 30,000; and that for smaller counties there be available without cost the services of a district health officer or other member of the state staff who, with the approval of the State Commissioner of Health, will act as county health commissioner for one or more of these counties.

3. That local health officers now in office be continued as assistants to the county health commissioner for the term for which they previously have been appointed, and thereafter at the discretion of the county board of health.

4. That at least three physicians be placed on the membership of the county board of health.

5. That cities be excluded from the county health districts except by vote of the city authorities, and that villages of more than 5,000 population be permitted to retain their boards of health as now provided by the county health district law.

6. That the effective date for the appointment of county boards of health be not later than September 1, 1931, and the appointment of county health commissioners be not later than December 1, 1931.

7. That the county board of health be authorized to delegate to the county health commissioner its present authority to abate nuisances affecting the public health.

10. HEALTH ADMINISTRATION IN CITIES

Although emphasis has been placed on the urgent needs in the rural areas and smaller municipalities for better health services, the Commission has been impressed also by the failure of many cities in the state to provide adequately for the health of their citizens.

Ideally, cities of less than 50,000 population should combine with the surrounding county for purposes of health administration. There are also instances where a city of larger size, particularly if the city contains the greater part of the county population, could join the county advantageously in a combined health administration unit.

The basic reason for shortcomings in city health service is the lack of an adequate salary and security in tenure of office for the city health officer with the frequent result that a part-time, poorly-trained official is appointed. There is needed for the position of health officer in all cities of over 50,000 population full-time service by qualified personnel not engaged in the practice of medicine. Similar qualified service for the smaller cities should be provided on the county basis with a deputy county health officer assigned to the city areas.

Because of inadequate budgets, such vital health activities as maternal and infant hygiene, venereal disease control and tuberculosis service are not receiving sufficient attention in many city health departments.

11. RECOMMENDATIONS

1. That in cities of more than 50,000 population health officers hereafter appointed be required to devote their entire time to the duties of their office.

2. That cities of less than 50,000 be encouraged either to employ qualified health officers at adequate salaries or to include themselves in a county department of health for purposes of health administration.

3. That more adequate budgets be provided in cities in order that basic health activities may be effectively conducted.

12. TUBERCULOSIS

Since 1907 the tuberculosis death rate has been reduced by 53 per cent in upstate New York, and by 50 per cent in New York City. This represents an annual saving of nearly 9,000 lives from this cause alone, and tuberculosis has dropped from first to sixth place as a cause of death.

The success so far gained should give an incentive for more direct application of successful experience; an increased effort will be peculiarly opportune in the next few years.

The fact must be faced squarely that the tuberculosis situation in the state is still far from satisfactory.

1. In 1930 there were approximately 9,000 deaths from tuberculosis in New York State, of which nearly 4,000 occurred upstate; by a conservative estimate there are 45,000 active cases of the disease, of which 20,000 are upstate. If modern facilities for the prevention of tuberculosis could have been provided in all parts of the state for all classes of people, a large proportion of these cases and deaths could have been prevented.

2. The tuberculosis death rate in the rural areas is not declining satisfactorily. This apparently is due to the inadequate facilities for prevention and care of this disease in rural districts, ordinarily considered more favorable to a low prevalence of the disease.

3. *There is a need for more sanatoria.* This is regarded by the Commission as of extreme practical importance at the present time. Since 1909, when the County Tuberculosis Hospital Law was passed, nearly all of the larger counties have created sanatoria. Many

of the smaller counties, however, most of which have populations of less than 35 000 have not found it possible to create such institutions It is not economical for such counties to maintain sanatoria As a result there are twenty five counties in upstate New York having a total population of nearly one million, without public sanatorium facilities Moreover the state and counties together have only about 60 per cent of the hospital beds necessary for the adequate treatment of tuberculous patients Further, a number of the smaller counties which have constructed sanatoria find it increasingly difficult to maintain proper standards because of cost In these counties without sanatoria and in small counties with sanatoria that cannot meet the accepted standards of medical and other care, there seems to be no alternative except the provisions of modern sanatorium facilities by the state

4 In many counties field services for the discovery nursing care, sanitary supervision and social welfare and relief, are not provided for tuberculous patients Although early diagnosis treatment and care are essential in the success of the control of this disease, 53 per cent of all the patients admitted to public tuberculosis sanatoria of the state are in the advanced or moderately advanced stages of the disease

5 Tuberculosis still takes largest toll among children and among men and women of twenty to thirty five years of age the period of their greatest economic and social value and the period when their responsibility to their families is greatest

The Commission has considered practical ways in which this situation can be met

(1) *The possibility of wider and more efficient application of existing knowledge* Actual experiments and demonstrations have shown that *further reduction can be effected* by the use of available methods of combating the disease These methods include (a) more adequate facilities for the early discovery of active cases as sources of infection, (b) protection of persons particularly infants and children against infection from active cases in the family (c) the hospitalization of cases in the early stages which serves the double purpose of protecting others from infection and providing the best opportunity for cure of the individual patient

(2) *The development of efficient city and local health departments is essential to effective tuberculosis activities* The experience of twenty five years has clearly shown that tuberculosis prevention and cure can be brought about most effectually only when integrated with well organized local health programs, when there is active cooperation with the medical profession and when proper facilities are available for hospital and social service relief But it is almost useless to attempt to coordinate state and other antituberculosis activities with *ineffective* local health administrations which are unable to discharge the responsibility for the discovery diagnosis reporting, and sanitary supervision of cases of the disease in the areas where they occur For this reason, the Commission regards the more rapid development of well rounded city and county health departments throughout the state as basic to the further development of the anti tuberculosis work of all agencies during the coming decade

(3) *The quality of services now rendered in the prevention and care of the disease and in the care of tuberculous patients should be improved* This involves better equipment for diagnosis qualified sanatorium superintendents assured by standards to be prescribed by the Public Health Council, more effective methods in tuberculosis clinics and sanatoria, better supervision of private nurses' homes for the care of tuberculous patients special instruction in tuberculosis for nurses and social relief personnel a further coordination of activities relating to tuberculosis as carried on by the Departments of Health Education and Social Welfare better facilities for the wider information of the public as regards the disease, more effective health teaching in the schools, uniform records of cases and of tuberculous families, and a marked improvement in the vocational training and rehabilitation of cases

These improvements are necessary if the facilities and services which the state has already undertaken to provide are to keep abreast of modern methods of preventing and treating the disease There is no new policy involved here rather it is the application of the sound principle that the state should do efficiently what is has set out to do

(4) *Social welfare and relief are an essential part of an effective anti tuberculosis program* The serious social consequences of tuberculosis to the affected individual and his family make it necessary that adequate provision should be made for the efficient administration of social welfare and relief Provision is already made for some welfare and relief activities but at present they are in adequate, poorly coordinated, and not well supervised The Commission is of the opinion that adequate provision should be made by new legislation to supplement the existing laws, that state, county and city tuberculosis hospitals and sanatoria should be authorized to employ hospital social workers, and that administrative improvements should be effected better to utilize the provisions in the Public Welfare Law and the Child Welfare Act for charitable relief in tuberculous families

At the present time a portion of the state is excellently served by a group of county tuberculosis sanatoria On the other hand there are twenty five counties with a total population of nearly one million in which there are no public tuberculosis hospitals and six counties in which existing institutions are not suitable for continued use The areas of the state not adequately served by public tuberculosis hospitals at present are in general the following (1) The Central Western area (2) The Central area (3) the Catskill area, and (4) the Adirondack area The twenty five counties without public sanatoria are each too small to build and furnish such services for themselves and in practice it has been impossible to secure combinations of counties for joint sanatorium service

It is clear therefore that a need exists for additional state sanatorium facilities to supplement the State Tuberculosis Hospital at Ray Brook This institution in the Adirondack area should be considered as a unit in a system of state sanatorium service with three new state district sanatoria in the other areas designated above The entire administration of the Ray Brook institution should be centralized in the Department of Health in place of the present divided responsibility in several state departments, except for this there should be no change in its present status until the three other district sanatoria are in operation When these become available incipient cases now sent to Ray Brook should be hospitalized nearer home in the nearest available sanatorium

A study of the annual average number of resident deaths from the tuberculosis in the three districts would warrant in each an adult bed capacity of 175 and in addition 75 beds for children The present bed capacity reserved for New York City cases at Ray Brook should continue to be utilized for such cases After needed alterations are provided the remaining beds would be available for patients in all stages of the disease from the nearby counties Except for the costs of construction for the state sanatoria the costs of maintenance, care and treatment of patients should be borne by the county from which the patient comes

The scientific facilities and technical services of the Department of Health and district state sanatoria should be made available for full cooperation with local authorities in providing field facilities for diagnosis, nursing and social welfare services Provision should be made also for epidemological clinical and other needed studies in tuberculosis

13. RECOMMENDATIONS

1. That the state provide three additional state district tuberculosis sanatoria of not less than 200 beds each for all types of tuberculosis cases to be located geographically with reference to the unmet needs of sections of the state; and that the cost of maintenance of patients in these sanatoria be borne in large part by counties served.

2. That legislation authorize the establishment of these sanatoria, and funds be appropriated as soon as possible for the purchase of sites and the preparation of plans.

3. That the administration of the state sanatorium at Ray Brook be centralized in the Department of Health and that when the other district sanatoria are constructed the facilities at Ray Brook be available as at present for incipient cases from New York City, and also for all types of cases from surrounding counties.

4. That the state provide through the Department of Health and the district state sanatoria facilities for: (a) cooperation with local health departments in the diagnosis, instruction and followup of patients; (b) scientific studies of tuberculosis; (c) instruction of physicians and nurses in tuberculosis diagnosis treatment and care; (d) a uniform system of records for use by local health authorities.

5. That field activities for the control of tuberculosis be co-ordinated with other local health activities under county departments of health with the consultative assistance of the state; and with an adequate social service and relief program of local public welfare authorities.

6. That the Public Health Council be authorized to prescribe the qualifications for the position of chief medical officer of all public tuberculosis sanatoria in the same manner as qualifications now are prescribed for other public health positions.

14. THE VENEREAL DISEASES

The venereal diseases constitute a great menace to public health by reason of their wide prevalence and the frequency with which they are followed by serious complications and disastrous end results. In its final report the Commission will deal with the whole subject of Social Hygiene, but will limit this report to the medical aspects of venereal disease control.

Prevalence. The Commission has reviewed critically information submitted by the Department of Health as to the number of cases of syphilis and gonorrhea constantly under treatment and the annual number of new infections. In addition to current reports and checks of laboratory examinations a special census was made of cases under treatment in 1927 and again in 1930. From these data the Commission finds that in upstate New York more than 15,000 cases of syphilis and nearly 11,000 cases of gonorrhea are constantly under treatment; that approximately 25,000 new cases of syphilis and 40,000 new cases of gonorrhea are diagnosed each year; and that between 1927 and 1930 the number of gonorrhea cases under treatment did not decline, while the number of syphilis cases under treatment increased by nearly 3,000. Present public health methods do not seem to be reducing the prevalence of these diseases.

Economic Importance. Syphilis ranks with cancer and tuberculosis as a chief cause of illness, death and economic loss. More than 2,000 patients in state mental hospitals are suffering from general paralysis of the insane, a syphilitic disease. This represents 10 per cent of the total admissions to these institutions, and it costs $8,000,000 to provide beds now occupied by these patients. In other words, if syphilis were eliminated as a public health problem, and the Commission believes this to be possible, $8,000,000 of the recent $50,000,000 bond issue for state institutions could have been saved. The cases of general paresis constitute only a small part of the total economic loss from syphilis, practically all of which can be saved for the state by well organized control methods.

For the control of syphilis accurate methods are available for prompt diagnosis and remedies are at hand which will speedily sterilize the infectious case. In these two facts lie the possibility of a marked reduction in prevalence and even the virtual elimination of syphilis as a public health problem. The Commission has reviewed data from European countries, particularly Great Britain and Denmark, which show that a marked reduction has occurred in the prevalence of this disease, due apparently to the utilization of diagnostic and treatment centers where modern facilities are freely available for the control of this disease.

Success may be expected in smaller measure in the control of gonorrhea by better facilities for diagnosis and treatment, and while gonorrhea is less serious in the individual case, in the aggregate it is almost as much a source of disability and economic loss as is syphilis.

There are fifty-four local clinics in thirty upstate counties which treat more than 6,000 new patients annually. There are twenty-seven counties, however, in which there are no organized public treatment facilities whatever. In many of the thirty counties with clinics the services are provided by cities and are not available to patients from the surrounding villages and rural areas. In standards of service these clinics vary widely Some are now functioning satisfactorily, while others are not meeting the minimum needs.

Another important service being rendered by the state and approved local laboratories is in the diagnosis of the venereal diseases. Nearly half a million Wassermann tests are made annually to diagnose or to control the treatment of syphilis.

The treatment of the venereal diseases at present is seriously handicapped by provisions of law which require that the patient be in an infectious stage and that he be indigent before being entitled to public treatment. In the many borderline cases, it is difficult to decide whether a given case is in fact infectious or is indigent. In consequence many cases in need of treatment do not secure such treatment from clinics or private physicians, and continue to be a source of infection or later become a charge upon the state by reason of general paresis, heart disease or other disabling end results. These restrictions of the law, therefore, should be removed.

15. RECOMMENDATIONS

1. That present laws be amended to provide for treatment of the venereal diseases as a public health problem, irrespective of whether or not the individual case be indigent or infectious.

2. That the county and city boards of health be required to provide facilities for the diagnosis and treatment of the venereal diseases which meet the standards prescribed by the State Commissioner of Health.

3. That provision be made in the programs of county boards of health for the diagnosis, treatment and follow-up of cases of the venereal diseases. If county boards of health are not generally established with state aid, then it is recommended that state financial aid be given to encourage local boards of health to establish satisfactory facilities for the diagnosis and treatment of these diseases.

16. CANCER

With more than 15,000 deaths from cancer in New York State in 1930, this disease ranks second among the causes of death. It is a public health problem, since by early diagnosis and proper treatment this mortality can be reduced.

For many years New York State has interested itself

in this problem through the State Institute for the Study of Malignant Diseases at Buffalo at which intensive research is being conducted and diagnostic service and treatment rendered to many people Last year approximately $300 000 worth of radium was purchased for this Institute, giving it the largest single supply of any institution in the world

During 1930 a total number of 1 697 new patients presented themselves for examination This was an increase of 247 over the figure for 1929 and is the largest number on record at the institution Of this total 1 392 were accepted for treatment Although many patients with cancer apply for treatment only when the disease is in the more advanced stages the record of cases which have been cured demonstrates the possibility of doing much to prevent deaths from this disease One such cancer center fails to meet the needs of the state

Local Diagnostic and Treatment Facilities Complete facts as to the number, location and efficiency of tumor diagnostic clinics, and the number of hospital beds for cancer patients are not available to the Commission at this time although sufficient information has been collected to show that many parts of the state are not provided with this needed service The Commission has been impressed by numerous reports of the lack of qualifications on the part of pathologists who make tissue diagnoses of cancer This is a serious matter, since an error on the part of the pathologist will result either in a needless operation or in the failure to operate when the patient is in need of it The Department of Health and the Public Health Council have done much to improve the quality of bacteriological service in public health laboratories throughout the state through a system of approval issued to such institutions The same principle should be extended to include pathological laboratories and pathologists

Services Needed The Commission has considered the suggestion that the state establish additional treatment centers for malignant disease but has refrained from making such a recommendation at this time in the hope that individual communities can be induced to provide themselves with the needed services in the diagnosis and treatment of cancer These services should include

(a) Special hospitals for the treatment of advanced cases of cancer

(b) Special departments of general hospitals where surgical and radiation therapy can be given by qualified experts

(c) Out patient services at these hospitals for the early diagnosis of cases

(d) Intermittent clinics in the smaller centers of population where expert diagnostic skill can be made available

County and city health departments can do much to follow up patients who have been treated to see that they return for the necessary continued treatment Local health departments also should organize diagnostic clinics and carry out a campaign of popular education Another important part of the program is to keep the medical profession fully informed as to what progress is made in the diagnosis and treatment of cancer

Division of Cancer Control The Commission is convinced that the organization of the Department of Health should embrace a division of cancer control, of which the State Institute for the Study of Malignant Diseases would be a part Through this division the present studies of malignant disease should be extended to include inquiries as to the nature and extent of the facilities available in the state for the diagnosis and treatment of cancer, and co operation should be given to county and city health departments, hospitals, medical societies and volunteer agencies in the development of such facilities The information which would be collected by such a division of cancer control during the next few years and the status of scientific knowledge concerning cancer at that time would enable a decision to be made as to what, if any, further activities should be undertaken by the state in regard to this important cause of death

17 RECOMMENDATIONS

1 That a division of cancer control be established in the Department of Health of which the State Institute for the Study of Malignant Diseases will be a part

2 That existing studies now being conducted at the State Institute in Buffalo be extended to include field studies of the nature and extent of facilities available in the state for the diagnosis and treatment of malignant disease

3 That the Department of Health conduct general public and professional education concerning the diagnosis and treatment of cancer and that it cooperate with local authorities and agencies in the development of needed services for diagnosis and treatment of this disease

4 That the present system of approval by the Public Health Council of the laboratories and of bacteriologists be extended by the Department of Health to include pathological laboratories and pathologists

18 MATERNAL AND INFANT HYGIENE

Among the most vital public health problems of the present day is that of adequate protection for the health of mothers and infants

During the past fifteen years the infant mortality in New York State has been cut in half, although among infants under one year of age there are still 60 deaths per 1 000 births There has been no corresponding reduction among mothers from causes incident to child birth and from these causes there are about 600 deaths annually upstate Added to this loss of life also, are about 3 400 stillbirths

Adequate care during pregnancy and childbirth will save the lives of many mothers as well as reduce materially the deaths among infants in the first months of life

A large proportion of pre school children are suffering from physical defects and disabilities which later lead to more serious conditions impairing normal growth and development An analysis of examinations made by the Department of Health of 5 000 rural children in its pre school clinics shows the following

Defects of ears nose and nasopharynx	44 per cent
Defects of mouth and teeth	35 per cent
Rickets	32 per cent
Definitely underweight	27 per cent
Orthopedic defects	23 per cent
Behavior difficulties	15 per cent
Visual defects	7 per cent
Defects of heart and lungs	4 per cent
No smallpox vaccination or toxin antitoxin immunization against diphtheria	90 per cent

These facts indicate roughly the great need of health protection for the pre school child

Health Department Activities Since its organization in 1914 of the first state unit for child hygiene in the United States the Department of Health has been deeply concerned with this problem In order to stimulate local child health activities, the Department has conducted nursing demonstrations, educational clinics and family health conferences particularly in the rural areas In addition, a field laboratory and teaching center for physicians and nurses has been operated for several years At present the Department of Health, at the request of the New York State Conference of Mayors, is engaged in a survey of existing facilities available for the protection of maternal and child health in the cities

Preventive work for saving the lives of mothers and children has been built up slowly by local health authorities. The need is being met in part by volunteer health effort in urban communities, but the activities of various groups are poorly coordinated. In the rural areas very little is being done.

Data from child hygiene stations and other public health studies indicate that less than 50,000 infants and children and less than 10,000 expectant mothers enjoy the benefits of health supervision. Comparing these figures with the child population and the number of births, it is apparent that a wide zone exists between the number of mothers and children needing care and those actually receiving it.

In addition to its own studies of this problem, the Commission has reviewed the findings of the White House Conference on Child Health and Protection and will incorporate in its final report many of the Conference recommendations which are particularly applicable to child health problems in New York.

The White House Conference stated: "Prenatal care is poorly organized and inadequately done and in the country as a whole only a small proportion of women receive adequate prenatal care." Throughout the entire report attention is called to the need for applying more widely the well established principles of health protection for mothers and babies. The findings of New York State support these views.

Special activities for conserving the health of mothers and children are inseparable from the health activities for the whole population and for best results must be integrated with other essential elements of a community health program. In the urban and rural areas alike, health authorities should assume leadership in and responsibility for health-conserving activities for mothers and children, under the general guidance of and with technical advice and assistance from the State.

The special services and facilities needed for maternity care include: Hospital services during confinement for all women in need of them; qualified medical care throughout pregnancy and during and after confinement; prenatal educational clinics; home nursing care; laboratory service and dental care. Medical care should be available similarly for infants and pre-school children not only during illness but for the prevention of illness. For those unable to pay private physicians, clinic services should be provided, and educational and diagnostic clinics (well baby clinics), should be available for all children.

Public health nursing is perhaps the most essential element of any program of maternity and infant hygiene. In rural areas the home nursing care is particularly inadequate and should be furnished by county health departments.

Real progress in providing the needed services for reduction in maternal and infant deaths can best be made through the organization of adequate county-wide health services, through county health departments in which maternity and infant hygiene is an integral and important part.

19. RECOMMENDATIONS

1. That activities for saving the lives of mothers and children need to be made a vital part of a general health program for the community. For rural and village areas this can be done best through the organization of county health departments.

2. That more extensive health measures for mothers and children should be organized and carried out in all local health departments.

20. SCHOOL HYGIENE

The Commission has given careful study to the complicated health problems presented by children of school age. It seems certain that under the present organization of health and educational services, both in the state and locally, adequate provision for the health of the school child must receive consideration both by health and by educational authorities.

This requires a close cooperation and a sharing of responsibility by these two agencies rather than a disassociation of the problem of services, or the administration of these services in their entirety by one agency alone.

It is generally recognized that health authorities cannot relinquish the responsibility for the protection of the health of school children, since they have a responsibility for the health of all citizens regardless of age, and for the best results there must be a continuity of program planning and of service through the different age groups.

It is likewise recognized that certain aspects of health promotion can be achieved only through education of the individual, and that for the school child the school system is the best agency to plan and carry out this service.

The responsibility of the two departments as indicated above can be met by activities organized under three main divisions:

(1) *Medical service* should provide for control of communicable diseases for periodic physical and mental examinations and correction of handicapping conditions; and for guidance of the educational program for health teaching.

Many communicable diseases are very prevalent among school children and the school offers an opportunity to detect cases in the early stages and to control such diseases.

The discovery of physical defects is of value only when steps are taken for their correction. Whenever inadequate treatment facilities exist in a community it should be the responsibility of the local health department either to provide such facilities or to see that they are made available through other local agencies.

The present provisions of law which require that each public school child receive a medical examination annually should be changed so as to provide for possibly less frequent and for more thorough examination. The importance of dental hygiene in the school health program warrants special attention.

Medical examinations should be the starting point of school health service both for correction of defects and for health instruction, and should be conducted so as to develop in pupils sound hygienic practices. A consulting medical service should be available to principals and teachers in the development of the general program of health education, and in dealing with specific problems as they arise in training the individual child.

(2) *School nursing* should assist in the correlation of health services of the school with the home and family in the interest of the school child. School nurses can translate the health teaching of the school into practice in the home, and are invaluable instruments in carrying to the home the needed encouragement for parents to have the physical defects of their children corrected.

(3) *Health instruction and training* should aim to equip each child to carry the full load of responsibility for his personal health by the development of sound health habits and practices as well as by the imparting of actual health information. The most important, but until recently the most neglected side of school health service, deals with the appreciation of personal and community health on the part of the pupil. This needs the services of the teaching staff and of physicians, nurses, dentists and physical education directors, all properly trained and working toward a common goal.

In three cities of the state, school medical and nursing services are administered by the city health departments. In other cities, villages and rural areas this is a function of the local boards of education. Examples can be cited of satisfactory administration under each

of these plans In the smaller villages and rural areas however, the present school units are too small to provide for these needed services by the employment of trained full time personnel Without discussing in detail the present inadequacies in the rural areas it can be stated that the problems are essentially the same as those discussed at more length under the general subject of local health administration

In rural areas it is obviously wasteful to maintain specialized nursing services and there is universal recognition of the desirability of a generalized nursing service which should include all of the special phases of public health nursing In a number of counties public health nurses now employed by county boards of supervisors or county boards of health are rendering a satisfactory generalized service which includes the school nursing

In the larger cities the Commission will make further studies as to the general efficiency of the two methods of school health administration now being followed

In the rural areas and small villages the Commission is convinced that school health services should be administered on a county or other comparable basis in order that the unit of population will be sufficiently large to permit the employment of full time personnel

In its final report the Commission will present a more detailed review of this problem At the present time it wishes to call attention to the desirable principle involved in school health administration but believes that the passage of legislation to change the administration of school medical and nursing service in the rural districts and smaller centers of population could well wait until county boards of health have been organized and are functioning

21 ORTHOPEDICS

The rehabilitation of the crippled child is far from being adequately secured throughout the state in spite of the participation of many authorities and agencies in this problem Both urban and rural surveys show that a considerable proportion of crippled children have not been discovered and that many others are not receiving proper treatment

Following the epidemic of infantile paralysis in 1916 the Department of Health organized traveling orthopedic clinics for after care in order to minimize the development of deformities in those who had been stricken with the disease

In 1924 a temporary State Commission was appointed to inquire into and report upon the number distribution and condition of the crippled children throughout the state, the existing facilities and legal provision for promoting care treatment education and general welfare of such children and to recommend methods to meet the needs

The Commission approved the orthopedic work of the Department of Health but stressed the necessity of extending widely the state's service for the treatment, education and rehabilitation of the handicapped Following its recommendation laws were enacted providing the present state program for the medical care and education of the physically handicapped

The law defines physically handicapped as any person who by reason of physical defect or infirmity whether congenital or acquired by accident injury or disease is or may be expected to be totally or partially incapacitated for education or remunerative occupation The state departments have limited their services to children with orthopedic and special malformations, severe defects of eye, ear nose, throat and speech, heart lung and nervous conditions Furthermore it is provided that the state may reimburse a county for one half the cost of treating and educating the handicapped upon the order of a children's court judge, with the approval of the Commissioner of Health for medical care and of the Commissioner of Education for education Substantial appropriations are made each year to meet these costs

Through the annual school census the Department of Education is expected to record all handicapped children between birth and 18 years of age and is also required to meet the educational needs of crippled children by providing special education and a placement service for the handicapped over the age of 14

Present Status of Orthopedic Services The orthopedic services of the Department of Health are now organized under the direction of one full time orthopedist, with four *part time* assistants and thirteen field nurses The nurses made a total of 11 833 home visits to orthopedic cases in 1930, and more than 400 clinics in about 170 centers were held, where approximately 10 000 examinations were made.

Number of Cripples The State Departments of Health and Education have records of approximately 18 000 active cases The White House Conference on Child Health and Protection concluded that there are in the country 2 5 cripples to each 1 000 of the population This estimate is too low for New York State Several intensive surveys in various areas warrant the conclusion that there are at least 40 000 cripples in the state one half of that number being outside of New York City The present problem is to make available adequate service for the cases now requiring care and steadily to extend that service until all children who need advice or help are found

Finding of Cripples Through the annual school census of crippled children through medical inspection in the schools through the records of clinics for infants and preschool children held by the state and local departments of health, and through reports from private physicians methods are available for the early discovery of orthopedic defects Instruction as to crippling conditions and the possibilities of correcting them should be given in training schools for physical instructors teachers and public health nurses The discovery of adult cripples is largely dependent upon the extent to which the physicians and the general public become conversant with the corrective methods available

Public Education The success of any continued effort for the early discovery of conditions which may lead to deformities depends upon the knowledge of the general public concerning these conditions and what can be done for them There should be developed a public education service to secure the help of all the various groups which can contribute to the early discovery of orthopedic conditions While local hospitals generally can be used only for the correction of the less serious forms of orthopedic conditions it is desirable for the state clinics to be held in local hospitals schools and health centers wherever accommodations make it possible, so that they may become educational centers

The experience of the Department of Health indicates that while county and local hospitals are useful for the treatment of some types of cases better results in major orthopedic adjustments and operations can be secured by using orthopedic hospitals or hospitals having a distinct orthopedic service The Department of Health has found no difficulty in securing beds for all patients in hospitals so equipped

Except for the additions planned and recommended at the New York State Reconstruction Home at West Haverstraw there is no immediate need for additional orthopedic beds in the state

There are several small privately organized reconstruction or convalescent homes in the state all receiving public funds for the care of cripples Such institutions should be organized only when they meet a proven local need

Private Agencies Many private agencies are interested in one way or another in the welfare of cripples

Some of these have been leaders in directing the attention of the public to the needs of cripples, and their initiative has been invaluable. The Commission believes, however, that the state has been wise in developing a program for the discovery, treatment and education of cripples under governmental leadership. It believes that private agencies will be useful only to the extent to which they direct their energies toward the common objective. It is suggested that no private agency should undertake work for cripples without definitely considering the relation of its proposed program to that of the state.

The administration of the rehabilitation home at West Haverstraw is now divided between the Health, Social Welfare, and Executive Departments. The Department of Health should be made entirely responsible for the administration of this institution.

Its work may be definitely integrated with the field services for crippled children, and should be affiliated with several of the medical schools as a training center both for physicians and nurses in the orthopedic field. The additions to this institution already authorized should be constructed as soon as possible.

Unimprovable Cripples. There is no provision in the state for cripples who cannot be further benefited by medical, surgical or nursing care and who have no means of self-support. A separate building should be provided at the State Reconstruction Home, with suitable facilities to care for such cripples.

County Health Units. As county health units are organized, it will be desirable for the larger counties to set up local services for the handicapped. Similar services should be available in the larger cities. The Department of Health should approve the plans for local orthopedic units and supervise this work.

Legal Recognition of Orthopedic Division. In the early days the orthopedic work of the Department of Health was technically assigned to the Division of Maternity, Infancy and Child Hygiene. Later the Commissioner of Health created a Division of Orthopedics. This division should be perpetuated by recognition in the Public Health Law.

22. RECOMMENDATIONS

1. *New York State Reconstruction Home.* It is recommended that the State Department of Health be made entirely responsible for the administration of the Reconstruction Home at West Haverstraw, in order that its work may be integrated with other health services for crippled children.

2. *Unimprovable Cripples.* It is recommended that a separate building be provided at the Reconstruction Home with suitable facilities to care for such cripples.

3. *Legal Recognition of Orthopedic Division.* It is recommended that the designation "Orthopedic Division" be legally authorized in the Public Health Law.

23. PUBLIC HEALTH NURSING

Public health nursing is generally recognized as one of the most essential factors in any health program and the people have come to regard the public health nurse as an indispensable aid. She is expected to give health guidance and assist in carrying out the instructions of the family physician and health officer.

There are approximately 1,400 public health nurses employed in the state, exclusive of New York City, by various agencies as follows:

County Boards of Supervisors	128
County Tuberculosis and Public Health Committees	15
Local Boards of Health	334
Local Boards of Education	353
American Red Cross	34
Industrial Corporations	146
Visiting Nurses' Associations	227
Other Private Organizations	53
Insurance Companies	72

Exclusive of school nurses, there are 640 nurses paid entirely from public funds, 555 from private funds, and 94 paid jointly from public and private funds.

Public health nurses are most unevenly distributed, large sections being poorly provided with this service. This is particularly true of the smaller communities and rural districts in which few private organizations are functioning and in which local authorities are not meeting their responsibility for a nursing service.

Many public health nurses have been appointed without special training or experience and the qualifications of the Public Health Council often are disregarded.

Nurses frequently are appointed for specialized fields such as tuberculosis, infant welfare, communicable disease nursing, tuberculosis control and school nursing, all working in the same territory. Sometimes three or four nurses meet in the same home for different branches of work. One instance is recorded where six nurses met in a home to the obvious disgust of the members of the family. A generalized plan of public health nursing is needed to replace present extravagant and uncoordinated efforts.

There is a lack of adequate nursing supervision of local nurses by a qualified local supervisor or by the nursing staff of the Department of Health. The efficiency of the service being rendered by the local nurse frequently cannot be determined because inadequate records are kept and no reports of work required.

There is urgent need for more and better qualified nurses engaged for a general nursing program with competent supervision, so that public health nursing may be developed to reach the standards now in effect in more favored areas. For all of the state outside of the larger cities this can best be accomplished through a county health department functioning under a full-time health commissioner with a qualified supervising nurse.

24. RECOMMENDATIONS

1. That county departments of health be developed throughout the state with a qualified supervising nurse under the direction of the health officer, who will supervise and coordinate the work of all public health nurses employed in the county.

2. That the Department of Health be given facilities to continue and extend its efforts to promote the qualifications of public health nurses in the state.

25. INDUSTRIAL HYGIENE

An important phase of the health-conserving activities of the state is assurance of safe and sanitary workshop conditions for industrial workers. If the growth of industry in the future continues as in the past this problem will assume even greater importance as a larger proportion of the population finds employment in industry.

The State Labor Law clothes the Industrial Board with broad powers of investigation and rule-making to safeguard employees in "any trade, industry, occupation or process" involving danger to their lives, health or safety. The board may make special rules to guard employees against elements of danger by "establishing requirements as to temperature, humidity, the removal of dusts, gases or fumes; by requiring licenses to be issued upon application to the Department of Labor as a condition of carrying on any such industry, trade, occupation or process; by requiring medical inspection and supervision of persons employed or applying for employment; and by other appropriate means." The rules made under the authority thus given the Industrial Board have the force and effect of law. The customary

method of preparing and adopting such rules is by appointment of advisory committees, composed of representatives of employers and employees and qualified experts, to advise the Industrial Board, which holds public hearings on the draft of the proposed rules before proceeding to their formal adoption. To conduct the scientific research necessary to enable the preparation of these protective and remedial rules, a bureau of industrial hygiene has been organized in the Department of Labor, and this bureau in the performance of its functions frequently seeks and secures the cooperation of the Department of Health and other agencies.

By these means several health-conserving codes already have been promulgated which are supplementary to the general and specific provisions of the State Labor Law *designed to "protect the health and safety of employees."* These codes require the removal of dusts, gases and fumes from contact with workers; regulate operations under compressed air and in tunnels; and regulate lighting in factories and mercantile establishments. The Industrial Board is now formulating a code to remove the hazards to employees engaged in the spray painting of automobiles.

The operation of the Workmen's Compensation Law since its enactment in 1913 has also contributed greatly to safeguarding the life and health of employees. It has stimulated active and successful cooperation between employer, employee and the state to reduce the sources of disabling accidents. Although insufficient occupational diseases are named in the law as compensable, yet the effect is substantial in minimizing the causes of the scheduled occupational diseases. It is evident that if the restricted schedule of acknowledged disabling diseases were replaced by a more general provision bringing under the terms of the law any disabling disease which in fact arises out of employment, the field of source-prevention cooperation would be extended, and a further reduction accomplished in the sum of personal disability and loss of productive service.

The Commission has not yet had an opportunity to study in detail the operation of the Workmen's Compensation Law in all of its aspects, since its presents complicated medical and legal problems.

Health Officers Enforce Labor Law. The Labor Law now provides for the inspection of certain manufacturing establishments and business offices located in cities, by the Department of Labor, but inspections of similar establishments located in villages and towns are made the duty of local health officers. This is not a duty which the local health officer is equipped to perform, and the inspection of these establishments wherever located should be done by the Labor Department.

Industrial Accident Prevention. Factory management and employees' safety shop committees have demonstrated a mutuality of interest in the application of preventive and first aid measures for the reduction of accident and disease causes which greatly aid the state in promoting the health of industrial workers. In this work local public health authorities should join by providing the scientific workshop surveys needed and by helping to draft safeguarding regulations.

Many new chemical compounds are constantly being developed and are finding industrial use. Frequently little or nothing is known of their toxic effects on the workers engaged in their manufacture or handling. The state has an important responsibility in investigating the effects of these substances and processes. This requires research facilities and a collaboration of chemists, pharmacologists, physicians and other scientists to ascertain the facts and to devise practical methods for protecting health.

The facilities of the Departments of Health and Labor should be available for such joint studies. In this way the duplication of laboratory and other facilities can be avoided.

Further Problems for Study. The health and medical services now provided by industries in the state, the relation of the general problem of medical care to wage earners, and the broader health influences of factory employment, including hours of labor, special industrial processes, wages and other factors—are subjects which the Commission will discuss in its final report.

26. RECOMMENDATIONS

1. That the present requirement of the labor law which makes it the duty of local health officers in villages and towns to inspect certain business offices and factories be changed so that this duty is performed by the Department of Labor as now provided by law *for business offices and factories located in cities.*

2. That the present limited schedule of occupational diseases be extended to include all diseases arising out of employment; and that the Industrial Board be given authority to make awards in cases of such occupational disease when it is established that the particular disability in fact arose out of the employment.

3. That the Department of Labor be given additional facilities to conduct investigations of health hazards in industry with a view to their prevention and that facilities be made available in the Department of Health for participating in joint investigations.

27. SANITATION

Greater progress than among any other group of diseases has been made in reducing typhoid fever and other infections caused by contaminated water and food. Most of the municipalities of the state have improved the quality of water supplies in recent years. The safeguarding of these supplies, however, requires the skillful operation and laboratory control of complicated purification proceses, and close state supervision of these methods.

Water Supplies. The Department of Health now supervises 620 public water supplies through periodic visits of engineers and constant checking of results by regular laboratory examinations. Although this supervision is exercised with good results over the operation of these plants, existing laws do not give the Health Department definite authority to approve plans for construction of new plants. The authority to pass upon the sanitary quality of proposed new water supplies is now lodged in the state water control board under the Conservation Law. This is an undesirable division of responsibility and should be remedied by giving to the Department of Health authority to approve the plans and proposed methods for purification of public water supplies as related to sanitary quality.

Sewage Disposal. The growth in population results in an increased pollution of the streams of the state and vigorous steps are necessary to insure better purification of sewage. Existing laws give the Department of Health authority to require that municipalities install and operate sewage treatment plants in accordance with approved plans. In practice the limitation on the allowable debt of the city and the difficulty in securing the affirmative action by municipalities, sometimes results in continued pollution of the streams. The Commission has considered a recommendation that authority be given to the state to abate the nuisance created by a municipality through the pollution of a stream in the same manner that nuisances on private property now are abated by public health authorities. This, however, is not now recommended since the Commission believes continued attempts during the next several years should be made to secure adequate purification of sewage under existing laws. If these attempts are unsuccessful, the Commission would recommend future strengthening of these laws by the legislature.

Industrial Wastes. The rapid growth of industry also adds sources of pollution to streams. At present the Department of Health has authority to require purification of industrial wastes when such wastes are combined with sewage but not when the industrial waste alone is discharged into the stream. This situation should be corrected by a change in the law to bring the control of stream pollution by industrial wastes not containing sewage under the same provisions of law which govern industrial wastes which do contain sewage.

Qualifications of Operators of Water Purification and Sewage Treatment Plants. A modern water purification plant or sewage treatment works requires competent local supervision. Without it, such an installation becomes worse than useless because a false sense of security is engendered. Conditions may be cited where the inefficient operation of water treatment plants has resulted in epidemics. Many properly designed sewage treatment works have been constructed but as a result of absolute neglect or improper operation, have failed entirely to carry out their function. In order that the money expended for such works may not be wasted and that the public health may be conserved, all operators of water purification plants or sewage treatment works should be required to meet qualifications prescribed by the Public Health Council.

State Parks. The state parks are being increasingly utilized for recreational purposes by citizens of this and other states. The presence of large numbers of people in these areas makes it important that all necessary sanitary safeguards be provided. Local health authorities are not in a position to exercise control and it therefore becomes the duty of the Department of Health to supervise the sanitary conditions of these areas and of the Department of Conservation to see that these requirements are met.

Milk Control. State-wide survey of the milk supply made by the Department of Health during the past year shows that although milk control in larger cities and a few county health districts with qualified milk inspectors was relatively satisfactory in the smaller communities milk control was very unsatisfactory and most of the milk below accepted public health standards. Improvement in local milk supplies cannot be expected so long as supervision is in the hands of poorly paid part-time local health officers with no special training, with no assistants, and with inadequate funds. The Commission is convinced that the safeguarding of milk supplies outside of cities, should be placed on a county basis with trained and experienced milk inspectors as a part of the county health department.

28. RECOMMENDATIONS

1. That the laws be amended so as to give the Department of Health specific authority to approve of plans for proposed new and extensions to existing public water supplies, in so far as the sanitary quality of the water supply is concerned.
2. That the pollution of streams by industrial wastes not containing sewage be regulated in the same manner as such wastes which do contain sewage.
3. That the Public Health Council be given power by law to prescribe the qualifications of and grades for operators of water purification plants and sewage treatment works.
4. That specific authority be given and sufficient facilities provided for supervision of the sanitary conditions of state parks.
5. That milk inspection services, outside of cities, be organized on a county basis as a part of county health departments.

29. PUBLIC HEALTH PERSONNEL

The efficiency of any effort depends upon the competence of the persons administering it. This is particularly true in public health, where a high degree of technical knowledge is essential, and the principle should be recognized by appointing officials and the public generally that physicians without additional special training are not qualified as health officers. The public health officer is a specialist comparable to other specialists in medicine, and needs as thorough postgraduate training and as sound a background of experience as does a competent surgeon.

During recent years the Department of Health has conducted short courses of instruction for local health officers and nurses. The courses for health officers embraced the problems of the average small village and town. Residence study has been limited to short periods and has been supplemented by correspondence courses for the benefit of the practicing physicians, who are the present part-time town and village health officers.

The courses of instruction and practical training for public health nurses have been particularly profitable, since the earlier public health nurses had been appointed with little or no special training. Others had received their training in large cities where very different problems exist. Utilization of nurses on the staff of the Department of Health as instructors has stimulated advanced study by these nurses and has made possible better state guidance of local nursing programs.

Health officers to be properly qualified for major administrative positions in public health need in addition to a good basic medical training, postgraduate training and experience in the theory and practice of public health.

Throughout the deliberations of the Commission and of its several committees, the necessity of securing qualified personnel for the conduct of modern health activities has been the subject of frequent discussion. The Commission has considered the measures which will be necessary to provide the considerable number of full-time county and city health commissioners who will be needed in this state during the next few years. The most likely applicants for these positions will be the present able local health officers. Their background of good medical education and their experience as local health officers, with an intensive course of instruction over a period of a few months, should give the minimum qualifications necessary. This should be followed by subsequent courses in succeeding years in special subjects. Later, at least one full resident year of study plus several years of public health experience on a whole-time basis, should be required for the position of county and city health officer.

In addition to instruction in the sciences underlying public health, field training stations should be established so that actual experience and supervised instruction can be acquired under model conditions.

The Department of Health should assume responsibility for leadership and should utilize its excellent facilities to conduct intensive training courses in public health which will enable otherwise qualified local men to do effective work in public health positions. The Department should cooperate also with one or more medical schools in the state in the development of courses in public health.

Courses comparable to those for general administrative health officers should be organized for other professional and technical personnel in the public health field.

The practical training of public health personnel is one of the most important functions which the Department of Health can exercise.

For a number of years the law has authorized the Public Health Council to establish qualifications for directors of divisions in the Department of Health, district state health officers, county health commissioners, local health officers, directors of approved laboratories, and public health nurses.

In a number of sections of this report attention is called to the necessity of extending the list of positions for which qualifications and grades are prescribed to include such personnel as pathologists in charge of approved laboratories, medical superintendents of public tuberculosis sanatoria and operators of water purification plants and of sewage treatment works

Career Service Regardless of the efforts to provide training and standards for qualified personnel it will not be possible to obtain for such training or to retain in public health positions persons of the needed professional and executive ability, unless appointment to and retention in office is placed solely upon the basis of efficient service. There also must be provided for the qualified health officer satisfactory compensation for the various positions, and an opportunity for advancement

30. RECOMMENDATIONS

1 That the present authority of the Public Health Council to establish the qualifications of public health officers, nurses and other personnel named in the law be extended to include operators of water purification plants and of sewage treatment works, pathologists in charge of approved laboratories, superintendents of public tuberculosis sanatoria and other professional and technical personnel as the needs arise.

2 That the existing activities of the Department of Health in providing special training for public health personnel be extended and that the Department cooperate with educational institutions in the development of courses in public health for health officers and other public health personnel

---

CONFERENCE OF SECRETARIES OF COUNTY SOCIETIES

The Annual Conference of the Secretaries of the County Medical Societies of New York State was held on Tuesday, September 15, 1931 in the Hotel Ten Eyck, Albany, N Y Dr I J Landsman, Secretary of the Bronx County Medical Society, was chosen to preside The representatives of twenty-five societies were present, as follows

Albany, Dr H L Nelms, Bronx, Dr I J Landsman, Broome, Dr G S Lape, Chautauqua, Dr E Bieber, Delaware, Dr W M Thomson, Dutchess-Putnam, Dr H P Carpenter, Erie, Dr L W Beamis, Essex, Dr L H Gans, Genesee, Dr F R Hall, Greene, Dr W M Rapp; Jefferson Dr P E Thornhill, Kings, Dr A N Thomson, Montgomery, Dr W R Pierce, Nassau, Mr Louis Neff, New York, Dr D S Dougherty, Onondago, Dr E E Mack, Orleans, Dr R P Munson, Otsego, Dr A H Brownell, Rockland, Dr W J Ryan, Saratoga Dr H L Loop, Schenectady, Dr S F MacMillan, Schoharie, Dr H L Odell, Suffolk, Dr E P Kolb, Ulster, Dr F H Voss Washington, Dr S J Banker

Seventeen of these counties were represented at the Secretaries' Conference last year Reports on twenty counties represented this year had been printed in the Journal during the year 1930 It seems to be a fact that those counties whose secretaries attend the annual conference rank above the average in the amount and scope of their activities

There were also present at the Secretaries' Conference the following official representatives of the Medical Society of the State of New York

Dr W D Johnson, President, Dr Charles Gordon Heyd, President Elect, Dr D S Dougherty, Secretary, Dr John A Card, Speaker of the House of Delegates, Dr James F Rooney, Chairman of the Trustees, Dr Aranow, Chairman Committee on Legislation, Dr Richard Kovacs, Chairman of the Committee on Physical Therapy, Dr H L K Shaw, Chairman of the Advisory Committee on Poliomyelitis, Dr J S Lawrence, Executive Officer, Dr Frank Overton, Executive Editor

The Chairman announced that during the past year, two secretaries had died in office—Dr E E Smith of Queens, and Dr Frederick Terwilliger, of Tioga County

Thirteen county societies had chosen new secretaries during the year

The papers and discussions were unusually practical and interesting Probably the most valuable feature of the proceedings was that the expression of opinions was both open and fearless Those present came to know one another intimately as they shared the confidences regarding the difficulties of their work. One of the greatest incentives to action is a knowledge of the motives and outlooks of other workers Physicians work best under the stimulus of comradeship rather than authority

The program that was announced was carried out as follows "Erie County and Public Relations" by Dr L W Beamis Buffalo "The Health Examiner," by Dr Alec N Thomson, Brooklyn "A County Society Publication," by Mr J Louis Neff, Mineola, Executive Secretary, Nassau County

Dr Beamis dwelt particularly on three features of the work of the Erie County Society

1 The radio talks

2 The legal incorporation of the society

3 The relation to endowed health organizations (The paper of Dr Beamis will be published in an early number of this Journal)

Many practical points were developed in the discussion of Dr Beamis' paper Dr D S Dougherty spoke of the necessity of incorporating the county medical society as a defense of the officers, especially in libel He said that New York County was incorporated at the same time with the Medical Society of the State of New York

Dr. Landsman described the relation of the Bronx Medical Society to lay health organizations, saying that members were on the executive board of the Tuberculosis Association, which is the leading lay health organization of the county, and has a large budget. The doctors also had a large degree of control of the health centers, directly through the County Society, and indirectly through the Tuberculosis Association. The centers are conducted for diagnosis only, and the patients are sent to their family doctors for treatment.

Dr. Alec N. Thomson described the relation of the Kings County Medical Society to the Visiting Nursing Association. The doctors committee had cooperated with the nurses in developing a set of standing orders. While the doctors and nurses had found it difficult to agree on the duties of each in fields that overlapped, yet the rules were satisfactory for months until the poliomyelitis situation produced some disagreements which, however, were quickly adjusted.

Dr. Dougherty described the Coordinating Committee of the County Medical Societies of Greater New York, consisting originally of Doctors Dougherty, of New York, Thomson of Kings, Podvin of Bronx, and Boettiger of Queens. To these were added the presidents of the county societies. The Committee meets monthly and discusses such common problems as health centers, school medical inspections and visiting nursing, and similar activities in which lay organizations were active. The work of the Committee was satisfactory and effective.

Doctor Dougherty also spoke of the necessity of providing the secretary with funds for clerical assistance and supplies. Even the smaller societies can hire a clerk for the few hours required for writing letters and reports, and filing the records.

Dr. Alec N. Thomson said that so many state and county medical societies had engaged full-time lay secretaries that the American Medical Association held a conference for them at the annual meeting last June.

Doctor Thomson said that the title of his paper, "The Health Examiner," referred to a monthly publication, and not to a doctor. The Journal is issued by the Five-County Health Examination Committee of Greater New York. The Committee first issued weekly bulletins to all the doctors in New York City, and now gets out the monthly journal in their place and sends them to the same mailing list of doctors. In addition, the Monroe County Tuberculosis Association buys a large number of copies for its members, and includes a page applying especially to Monroe County. The welfare organizations of Nassau County also buy copies.

The Examiner contains scientific articles on periodic health examinations, and is intended principally for physicians. Its cost is borne by several lay health organizations, including the Tuberculosis Association. Advertisements also help to defray the expenses.

Mr. Louis J. Neff, lay secretary of the Nassau County Medical Society, discussed the monthly bulletins of county medical societies, and said that they were issued in seven counties—Bronx, Erie, Kings, Nassau, Ontario, Queens, and Suffolk. Nassau had started its Bulletin as the organ for a campaign to establish a county hospital, and had carried the referendum of voters at general election by a vote of eight to one. The Bulletin had proved so successful that every doctor is in favor of it, and a copy is sent to every lay health worker in the County. The mailing list contains 1,800 names. The cost is borne largely by the lay health organizations.

Dr. W. D. Johnson, President of the Medical Society of the State of New York, emphasized the fact that the community is the patient of the Medical Society; and that an important reason for the existence of county medical societies is that of giving advice how the community may do its part in making a medical service available to every person. The new Welfare Law is a great step in that direction. In contrast with the external outlook of the county society is the individuality of the family physician. Doctor Johnson quoted Kipling to the effect that the only individual from whom one cannot escape is oneself, and each of us should be good to it, and thereby be best able to give medical service to the public.

Dr. Charles Gordon Heyd, President-Elect of the State Society, gave an intimate talk on the necessity of considering well the actual need of a new activity before starting it.

Dr. John A. Card, speaker of the House of Delegates, asked the members of county societies to choose men of broad views and extensive experience, and to return such men year after year in order that the legislative body of the State Society may have a large number of members who are well versed in medical society activities.

Doctor Card also explained the new rates of indemnity insurance, and said that this year the rates were substantially lower than in the past. The Aetna Life Insurance bases its rates on the actual cost of defense and of payments for indemnity; and after a fixed charge is made for a minimum amount of insurance, all additional insurance is issued at a reduced rate.

The Aetna Insurance Company has also offered to accept a premium in installments if the doctor wishes to pay it in that way.

Dr. Henry Aranow, Chairman of the Committee on Legislations, outlined the course of action which the county societies should take in assisting the State Committee.

Dr. James F. Rooney gave the secretaries some interesting advice based on his extensive experience with legislators.

Dr. Richard Kovacs, Chairman of the Special Committee on Physical Therapy, gave the following report:

"The Committee on Physical Therapy urges a definite activity in physical therapy in every County Society for two reasons: (1) To furnish patients with full medical care by the medical profession itself. (2) To counteract abuses and ridiculous claims by technicians and drugless practitioners. Every County Society should have a paper on some phase of physical therapy at least once a year; and physical therapy cases should be presented at staff meetings of hospitals as often as possible in order to encourage intelligent discussion of the possibilities and limitations of physical measures.

"A committee on physical therapy, even it be only one man, should be appointed in each County Society. Members of such committees will be regularly invited to the meetings of the State Committee for effective cooperation. The Chairman and members of the State Committee on Physical Therapy will be pleased to address any County Society or District Branch. The Committee on Medical Education, on proper request, provides a lecture course in physical therapy to any County Society. Since there might not be enough men interested in physical therapy in one county, an attempt to combine the interested membership in several counties may be worthwhile."

In order to get more definite information from the counties which so far have not had any activity in physical therapy, a short questionnaire was handed out to the Secretaries present. The Secretaries of Broome, Delaware, Fulton, Saratoga, Schenectady and Ulster Counties signified their willingness to plan definite activities as suggested by the Committee.

Dr. Thomas P. Farmer, Chairman of the Committee on Public Health and Medical Education urged the county secretaries to send him information regarding the graduate courses that they wish. He expected that each lecturer would prepare an outline of his talk, to be mimeographed and sent to each member in advance of the meeting. He also said that his committee and the committee on Scientific work would be on call to assist secretaries in making up programs of county society meetings.

There was considerable discussion regarding the operation of the Welfare Law, it being developed that many county societies had not yet taken steps to enter into agreements with their County Welfare Commissioners regarding cases to be treated and the payment of doctors for giving medical service. Suffolk County was quoted as a county in which satisfactory agreements had been formed. (See this Journal, February 15, 1931, page 225; and April 15, page 476.)

The members and guests dined together at noon, and then continued in session until three o'clock, without a moment of dullness in the entire day.

THIRD DISTRICT BRANCH

The round of annual meetings of the eight District Branches of the Medical Society of the State of New York was begun by the Third, which held its meeting on Wednesday, September 16, 1931, in Sharon Springs, Schoharie County, with the President, Dr. H. L. Odell, of Sharon Springs, in the chair, and the Secretary, Dr. W. M. Rapp, of Catskill, recording. Fifty members were present.

The morning session was opened with a moving picture on "Infections of the Hand," produced by the Eastman Company of Rochester. The picture had a great value in that it visualized the spaces in which infectious matter collects, and the usual routes by which it travels. The picture also visualized the incisions to be made in order to open the spaces the most effectively, and with the least after-harm. One seeing the picture for the first time, realizes the complexity of the problem both anatomically and surgically.

The second number was an address on "Congenital Syphilis," by Dr. Thurman B. Givan, of Brooklyn. Dr. Givan has conducted a clinic on congenital syphilis in the Long Island College Hospital for twelve years, and has followed many cases through childhood and youth, and even to the prospective marriage of some of the patients. He lectured for half an hour on the pathology, signs, and symptoms of the disease, and then showed lantern slides illustrating its more common phases. He left an impression of hopefulness, for the patients respond well to treatment, even those threatened with blindness from interstitial keratitis. Dr. Givan said that congenital syphilis is more common than is usually supposed, and he closed with a plea for the early recognition and treatment of the cases.

A noon luncheon at the Mansion House was followed with brief words of greeting from some of the officers of the Society. Dr. W. D. Johnson, President, wished for the return of the old system of preceptorships, and quoted the poet, Robert Burns, on the influence of a leader on his fellowmen; and also Charles Darwin, who gave credit to Professor Henslow for his friendly inspiration while he walked the fields with his students.

Dr. John A. Card explained the newer developments in the indemnity insurance policy issued by the Aetna Life Insurance Company to the members of the State Society, including reduced rates, and provision for the installment payment of premiums.

Dr. D. S. Dougherty, Secretary, recalled the hospitality of one of the local doctors at the last meeting of the Third District Branch in Sharon Springs, when the day was exceedingly cold and the ride to the village had been long.

The afternoon program included two papers. Dr. Russell L. Cecil spoke on "Arthritis," drawing upon his extensive experience in both the research and clinical phases of the disease.

Dr. Smith Ely Jelliffe, of New York, gave a paper on "The Mental Apparatus and Internal Medicine."

THE DAILY PRESS

Reg'lar Fellers — Cured for Life — By Gene Byrnes

From the New York Herald Tribune, September 4, 1931.

NATURAL ALCOHOL IN THE BODY

The New York Times of September 3 comments on the announcement of Dr. Gittler to the American Chemical Society, that alcohol is present in the brain and liver of every human being. The *Times* says:

"In an autopsy he has taken a half-drop of pure ethyl alcohol from the brain of a teetotaler. This leads him to the conclusion that the presence of the fluid in the human body does not necessarily preclude clear thinking.

"One of the arguments for prohibition is that it keeps alcohol out of the human system. But if nature, which in plant life and bacterial action has been indifferent to the Eighteenth Amendment, has decreed that even the human body cannot be surrounded by the law, the issue comes back to temperance, not prohibition. Dr. Gittler would admit that too much alcohol is bad for human creatures. That is what temperance advocates used to contend. The path leads from that to sensible regulation."

ADDISON'S DISEASE

Scientific societies other than medical frequently discuss diseases. *The New York Times* of September 4 has an editorial which says:

"Before the American Chemical Society session at Buffalo, Professor Frank A. Hartman read the last instalment of an exciting scientific serial that recounts the chemists' victory over Addison's disease.

"Here, for example, is a man so far ravaged by Addison's disease that he cannot retain food. Cortical extract is administered. Two days later he is eating a double portion of beefsteak. A woman debilitated to the point of death runs about in the hospital corridor five days after treatment.

"There are ninety such cases with many astonishing 'cures.' Physicians and chemists will not be misled by them. Thyroxin, pituitary products, insulin, cortin—none of the extracts of the ductless glands cures anything. We deal with hormones, a Greek name for minute quantities of chemicals carried by the blood stream to regulate organic processes in all parts of the body. One part of adrenalin in twenty million parts of blood is enough to keep the heart beating normally. But let one of the ductless glands fail in its duty and the body, even the personality, changes. The hypodermic needle must come to the aid of defective glands not once but always. So it is with insulin, which has shorn diabetes of its terrors; so it is with the new cortin; and so will it probably be with hormones which are still to be discovered, and which may make it possible to retain the vitality and the imagination of youth long after the biblical span of life."

MATERNAL INTEREST IN CHILD HEALTH

The New York Times of September 18 carries a news item on a survey of maternal interest in child health conducted by Dr W M Bomar of Teachers' College, Columbia University The findings of Dr Bomar confirm what every doctor already knows—that mothers in New York City have such great confidence in the supervision of public health matters by the Department of Health, that their interest in the sources of supplies of water, milk, and other foods is lax But Dr Bomar also reports a lack of interest in other civic affairs, and says

"Mothers rarely participate in community activities, Dr Bomar's survey shows There is much church work, she reports and next in importance is the care for dependent children and membership in parent-teacher organizations The activity in which there is the least participation is that of the Boy Scouts—only 1 2 per cent of the mothers are actively engaged in helping the movement

"Explaining that this is significant, Dr Bomar notes that in the collective reports from the 483 mothers interviewed many of them expressed interest in the Boy Scout work She concludes that

"The lack of participation in this activity, as contrasted with the relatively high rating in importance which it received, clearly indicates that the homemakers are content to wait for others to initiate and keep alive the activities which may vitally affect the health and happiness of members of their families

"There is no correlation between the activities receiving the highest rating in importance in any given city and those in which participation was greatest This clearly indicates that there exists on the part of homemakers in all parts of the country an attitude of complacency so far as participation is concerned, in regard to certain community activities, especially those more closely connected with civic and municipal government"

A rural community is criticized for its lack of civic interest, chiefly on the ground that it is rural The largest city is similarly criticized because it is too big to give heed to the protests of an individual Public health work in a great city is necessarily paternalistic

---

REVENGE

One of the items of policy of the NEW YORK STATE JOURNAL OF MEDICINE is that it shall not indulge in personalities, for explanations and apologies are seldom understood Moreover most writers of the criticisms sent to the JOURNAL are inspired by a sincere desire to be helpful Even if the criticisms should be spiteful, we subscribe to the closing lines of the following poem by James J Montague printed in the *New York Herald Tribune* of August 26

"When Franklin walked munching a loaf down
the street
He wasn't annoyed or embittered
When a pretty young damsel he happened to meet
Cast her bright eyes upon him and tittered
The future philosopher finished his bread
With never a pause nor a falter
And giving her ogle for ogle, he said,
'I shall lead you some day to the altar
You can't smile at me with impunity, kid,
As you later will learn,' and the young lady
did

"When Byron was turning out pages of rhyme—
Some of which will be never forgotten—
The critics who harried the bards of his time
Said all of his poems were rotten
But Byron filed points on the quills he employed
To give them the keenness of skewers
And then in a couple of lines he destroyed
The once over caustic reviewers,
Till the toplofty brethren agreed to a man
That George was one bird it was unsafe to
pan

'Revenge, gentle reader, is sweet to the taste,
But we seek for it swiftly and blindly,
At every affront we endeavor to paste
The person who's used us unkindly
Though a crushing retort fills the bosom with
joy
And acts as a balm to one's ire,
Too often the weapons we try to employ
When the trigger is tickled misfire,
It is fine to reply with attack to attack,
But only a genius knows how to come back

(*Continued from page* 1228)

Grievance Committee: The Committee on Public Policy, which has charge of legislation, asked for instructions as to whether or not it should introduce the Grievance Committee bill which was defeated in the Senate last year. The bill was as follows:

"The State health officer, the Secretary of the State board of medical examiners, and the attorney general or deputy attorney general are hereby constituted ex-officio a state medical grievance committee to investigate, hear, and act upon practices by persons licensed to practice medicine and surgery under section 147.17, that are inimical to the public health. The State health officer shall be chairman of the committee. Meetings of the committee shall be held at the call of the chairman. Any member thereof shall have power to subpoena and swear witnesses, and take evidence. The committee shall have power to warn and to reprimand, when they find such practice, and to institute criminal action or action to revoke license when they find also probable cause therefor under criminal or revocation statute, and the attorney general may aid the district attorney in the prosecution thereof."

Medical Defense: The Chairman of the Committee on Medical Defense, Dr. A. J. Patek, reported as follows:

"I am pleased to report that during the past year your Society has been unusually favored: The smallest number of cases in its history has been referred to it for defense. A total of seven cases compares very favorably with the large number which has, in the past, come to our notice. Of these seven, four are in the hands of other protective organizations, and will in all likelihood be conducted with our attorney as counsel only; one was settled at a very nominal figure through an insurance carrier; two have not been reported upon since first notice of suit was posted. In addition to the above seven, there were two who were threatened, but no further action taken.

"It has not yet been possible to publish letters of advice from our Counsel, or analyses of cases that should act as object lessons, as was promised our subscribers last year. We are, however, continuing our efforts to this end, and trust these proposed 'lessons' may be forthcoming during the coming winter." (This recommendation is in line with the policy of the New York State Journal of Medicine in which every issue includes reports of actual cases handled by the Legal Counsel.)

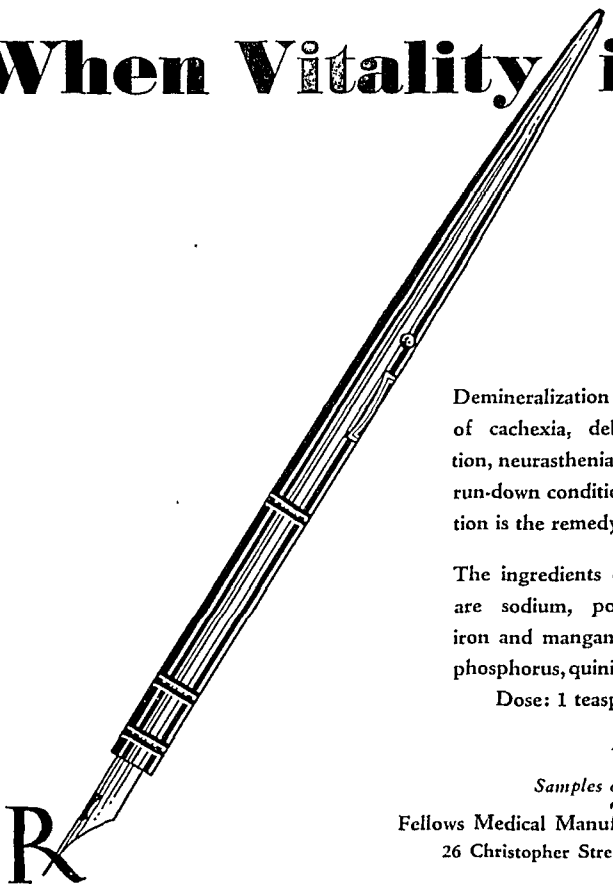
Undergraduate Medical Education: The Committee on Medical Education and Hospitals re-

(*Continued on page* 1232—*Adv. xxii*)

Definite dosage
Ease of administration
Sensible economy

Each pill contains 0.1 gram (1½ grains) of physiologically tested digitalis leaves. The finished pills, too, are biologically assayed, thus giving re-assurance of their activity.

Each pill represents 15 minims of the U.S.P. tincture and permits of more accurate dosage than do liquids, as drops may vary in size.



These pills contain digitalis in its completeness and not any separated or extracted part of it, therefore present the entire therapy of this valuable drug.

Physician's trial size package and literature sent free upon request.

ported the two important items of progres undergraduate medical education as follows:

"During the year 1930-31 orientation con ences for first and second year medical stud were inaugurated. These conferences are ur the direction of members of the clinical fac and are attended also by members of the fac of the basic sciences. The aim is to stress correlation between the basic sciences and c cal and preventive medicine.

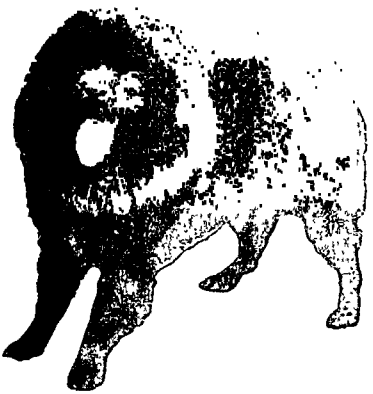
"The State University is continuing its pre tor system for the instruction of fourth medical students. One-quarter of the fo year is now spent by each student in Milwau and this Milwaukee quarter under the prece plan has proved of great value in giving the dent insight into the medical problems prese by a larger city."

Graduate Education: The Committee on M cal Extension reported as follows:

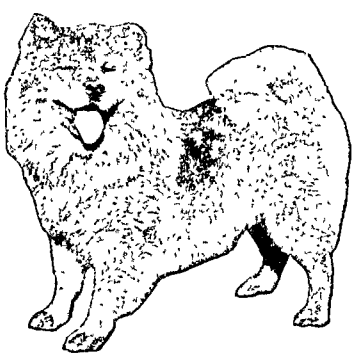
"The Society's program of postgraduate m cal instruction, given annually in Wisconsin s 1928, reached in the year closing on June 30 point of its highest success. In number of ture courses given and in total enrollments a mark was set. Three courses were given in t entirety and a fourth started. The latter, co ing Obstetrics and Gynecology, will conti through the summer as a part of the con year's program."

The following courses were reported: Inte medicine, two series, June to September, 1 enrollment, 292. Insulin, May 18-23, 1931, rollment, 309. Popular lectures on diabetes v also given in connection with the professional struction, and were attended by 915 persons. Clinical Larynx, enrollment 18. Obstetrics Gynecology, enrollment, 113.

The Committee also conducts a medical libr service, in which medical periodicals and bo are loaned to physicians:



"Those who probably appreciate best the m cal library facilities are physicians listed as 'r ulars.' Physicians thus classified obtain each sue of a selected journal as soon as the libr receives it from the publishers; the only obli tion is five cents plus postage. For book pa ages the charge is postage both ways and wrapping cost.



"Having a record of the periodical desired r ularly by the physician, the library sends it e week, month, or quarter, as the case may thus freeing the physician and the librarian the trouble of handling a special request for e number. In the case of periodicals in much mand by many physicians, the library subscri for enough copies to serve the group, thus red ing the waiting list to a minimum.

MEDICAL EXAMINERS OF ARKANSAS

The July number of the *Journal of the Arkansas Medical Society* contains the following report of Dr. S. J. Allbright, Secretary of the State Board of Medical Examiners:

"Since the last report forty-four certificates of license to practice have been issued by this board. Twenty-five were issued by examination, one graduate of the University of Tennessee School of Medicine and twenty-four graduates of the University of Arkansas School of Medicine.

"Nineteen certificates were issued by reciprocity from other States coming from Missouri, Virginia, Tennessee, Louisiana, Illinois, Iowa, Kansas, Mississippi, New York, North Carolina, Oklahoma and Texas.

"Each applicant for license must have the approval of the Basic Science Board, whether he makes application for license by examination or by reciprocity; this has not disturbed our reciprocal relations with other States.

"Three licenses were revoked during the year. In one case the licentiate had been convicted and served a term in prison for forgery.

"Another had been convicted and served a prison sentence for violating the Narcotic Law. And the other was revoked because the license upon which his certificate was issued by reciprocity was revoked for cause in the original State.

"One license which had been revoked, 1926 was reinstated upon petition of a majority of the members of the County Society in which the applicant was a member.

"Thirty-seven licentiates have been certified to other States for license by endorsement. These have been accepted by Texas, Wisconsin, Kansas, New Mexico, Louisiana, Ohio, Missouri, Oklahoma, Michigan, New Jersey, California and Alabama.

"The board has been instrumental in securing the conviction of one man who has been practicing medicine in Arkansas for twenty years without license.

"There are more illegal practitioners in various parts of the State. In some places it seems difficult to get the district attorney to take action, in other instances the illegal practitioner moves when he receives a letter from the board and is not heard of again until he has been practicing in some other community six months or more.

"The only solution to this is annual registration of all physicians, as Colorado and several other States are now doing."

LIQUID PEPTONOIDS WITH CREOSOTE

COMBINES the active and known therapeutic qualities of creosote and guaiacol with the nutritive properties of Liquid Peptonoids and is accordingly a thoroughly dependable product of definite quantities and recognized qualities as shown by the formula:

Each tablespoonful represents

ALCOHOL (By Volume)	12%
PURE BEECHWOOD CREOSOTE	2 min.
GUAIACOL	1 min.
PROTEINS (Peptones and Propeptones)	5.25%
LACTOSE AND DEXTROSE	11.3%
CANE SUGAR	2.5%
MINERAL CONSTITUENTS (Ash)	0.95%

It acts as a bronchial sedative and expectorant, exhibiting a peculiar ability to relieve *Bronchitis—acute or chronic.* It checks as well a persistent winter cough and without harsh or untoward effect. It is agreeable to the palate and acceptable to the stomach—with merit as an intestinal antiseptic. Supplied in 12 oz. bottles.

PUBLIC RELATIONS IN MAINE

The public relations of the medical profession were discussed in the July number of the *Maine Medical Journal* by the President of the Maine Medical Association, who said:

" 'Our Committee on Public Relations, with the assistance of our State Secretary, has made a medical survey of Maine, in order that we may intelligently state how well Maine is served by doctors.

" 'We find that our public has not been neglected. Many statements have been made loosely in regard to lack of medical care. For instance, as the committee chairman has stated to you, and contrary to newspaper reports, in Aroostook County only two and one-half per cent of the population are ten miles or more from a doctor. In eight other counties from four per cent to zero are ten miles from a doctor. We have now a basis for tabulation and comparison.

" 'Your Secretary has promoted cooperation between local, county, state and national associations and other health agencies. When he has been able by continued service to establish contacts with public lay audiences, he can accomplish more in extending the intelligent appreciation of health problems and thereby the influence of the State Association.

" 'It has been claimed publicly in this State that we need more doctors graduated, and that we suffer from the closure of our medical school. However much we lament the closure of our State Medical School and feel it a blow to our prestige, we resent any implication that we should be turning out a cheaper grade of doctors who would be satisfied with the rewards of a past generation. It is enough to say that it will never be. The United States is now absorbing 5,000 new medical graduates a year, which is faster than population growth. A partial payment subsidy by rural towns in order to have a twelve-months-in-the-year doctor is a generous gesture with apparent need, but is not a solution of the economic question. It is a temporary expedient and it is claimed that it increases the number of non-paying patients in such towns.' "

FOR THE WANT OF

A BETTER NAME

...it is called a tonic—Guiatonic. And it lives up to its name.

Coughs due to colds give way to its unyielding influence because Guiatonic contains creosote and guaiacol.

Convalescence hastens to yield its place to Recovery, because Guiatonic stimulates lagging appetite, and supplies iron, manganese, calcium, potassium, phosphorus to replenish the depleted mineral supply of the body; while quinine and strychnine add their urge to the depleted cells to help themselves toward regeneration.

EDUCATING THE HOUSE OF DELEGATES IN FLORIDA

The leaders of the medical profession in Florida feel the need to supplying the members of the House of Delegates with information regarding the questions before them. New York meets the problem by publishing the annual reports and the personnel of the reference committees in the Journal a month before the meeting; and by urging all those who wish to present resolutions to send them to the Journal for advance publication. The June Journal of the Florida Medical Association presents a plan of educating the delegates in the following editorial:

"At every annual session many questions are brought before it for consideration and action. It frequently happens that the individual members of this body are called upon to vote on matters which have only been brought to their attention a few moments before. Under such circumstances, careful consideration and thoughtful study of the problem are to say the least, extremely difficult. Decisions may be made which a calm second judgment, later on, would not support.

"The Journal feels that it would be of advantage if some of the questions which might be brought before the House of Delegates at the Sarasota meeting could be presented from time to time in its pages for consideration. In this way the subjects would be brought to the attention of all members of the Association, and not limited simply to that minority of our membership which attends the State meeting. Discussions between individual members and on the floors of the various county societies would go far toward crystallizing the sentiment of the membership on the questions involved and would also enable the individual delegates to vote more intelligently when these questions were considered at the annual session.

"With this thought in mind, this issue carries an editorial entitled 'Shall we have a President-Elect?' It is hoped that all members will read this article carefully. The Journal invites comments upon this plan from its readers. Letters received are to be published, in full if space permits."

HEALTH MAGAZINE OF KANSAS

We have just received the first number of *Folks,* a popular health magazine published by the Kansas Medical Society, as announced in our Journal of August 1, 1931, page 998, and of April 15, 1931, page 504. The new magazine consists of sixteen pages, of the size of an ordinary medical journal. It is divided into four departments: 1. Scientific; 2. Home Folks; 3. Editorial; and 4. Little Folks.

Six scientific articles are published. The first is an introduction of *Folks* to the people of Kansas, and says:

"It is the intention to present in this magazine problems in health, of particular interest to Kansas people, as this varies in different states; for instance, the problems in Arkansas or Mississippi are quite different in many respects from ours. We want this magazine to have a distinctive 'Kansas flavor.' "

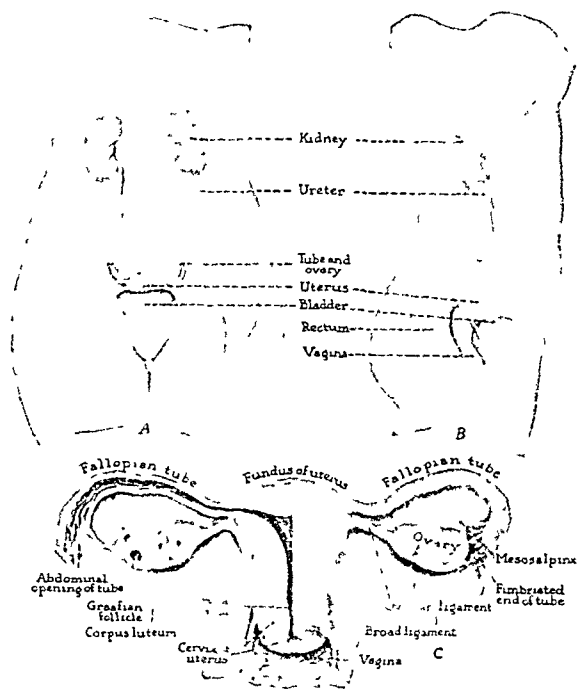
"The Romance of Typhoid Fever," describes the discovery of the cause of a water borne epidemic in Pennsylvania.

"Get Well in Kansas," describes a county tuberculosis sanatorium.

"How a Doctor Lost His Practice," is the most interesting and well written. It tells how Dr. Brown cut his income in half by suppressing epidemics of typhoid, smallpox, and diphtheria.

"A Column on Things that You Should Know About Your Family Doctor," is a plea to find out whether or not he keeps himself up to date by promoting his county medical society, and says:

"In this day and age when matters pertaining to the welfare and treatment of the sick are changing, advancing almost as constantly and rapidly as are the styles of milady's bonnet, the layman who does not know about the way his doctor keeps up to date or, as is frequently the case, fails to keep up, is paying for service that he does not receive.



"You have every right to know these things. Learn if your doctor discusses medical matters with his colleagues at medical meetings as freely as he does with you, or perchance with the reporter for the local paper."

There are also articles on automobile accidents and cancer.

The department of "Home Folks" contains an article on ventilating the sick room and the use of cereals, and recipes from pre-Volstead days.

(*Continued from page* 1238—*Adv. xxiii*)

There are also "Questions and Answers" on spinach, how much water to drink and heights and weights.

There are four editorials on the subject 1. No Secrets in Scientific Medicine; 2 Liver, A Remedy but not a Cure for Anemia; 3. Vitamins; 4 Mosquitoes—Some Prevalent Notions

The department "Little Folks" contains a few stories, with the usual "Lessons" appended.

Altogether *Folks* does credit to the Kansas Medical Society.

JUDGES AND COUNTY MEDICAL SOCIETIES IN MINNESOTA

The August issue of *Minnesota Medicine* records the reaction of county judges to the presentation to them of the roster of the State Medical Association, and says —

"Twenty-one out of forty-two reports from probate judges in Minnesota counties indicate that officials are wholly in favor of organized medicine and eager to cooperate with its membership

"This desirable state of things is revealed in the interesting reports that are coming in to the state office these days following the bestowal through members in the county seats, of the 1931 rosters of the association upon all county judges of probate in the state.

"Of the other twenty-one reported, only four seemed to the members concerned to be definitely indifferent or uninterested in the state association and organized medicine in general

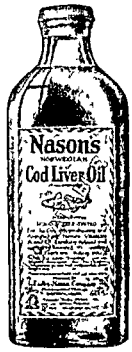
"Many enthusiastic statements were quoted from the twenty-one friendly judges by reporting members.

"'Thank you. That is fine! said the Judge,' reports the Stillwater member. 'He thinks an M D. not belonging to a county society is like a lawyer not belonging to the bar association and NO GOOD.'

"Other emphatically friendly officials were discovered in Detroit Lakes, St James, Windom, Owatonna, Crookston, Little Falls, St. Cloud, Chaska, Wheaton, Ortonville, Glencoe, Cambridge, New Ulm, Marshall, Two Harbors and Worthington.

"Several judges in the various counties were not approached at all, mainly for the reason that, all of the physicians in the county being members of the association, the members felt sufficiently assured of official cooperation anyway.

"Two judges were reported in their dotage as a sufficient reason for lack of active interest in the matter. Another was rather astonishingly quoted as surprised to know that there was such a thing as a medical organization. Such a thing as expressing himself adverse to organized medicine was beyond the scope of his comprehension."



Don't Let Your Patient Grope in the Dark!

Your patient who goes to buy Cod Liver Oil may be offered inferior and untested commercial oils Unadvised he may purchase them

But if you will recommend or prescribe Nason's Palatable Cod Liver Oil **by name,** he is sure to get a Cod Liver Oil—pleasant to take and of highest recognized vitamin potency.

PUBLIC RELATIONS COMMITTEE IN FLORIDA

The August issue of the Journal of the Florida Medical Association has an editorial comment on the newly formed Public Relations Committee:

"This committee has for its aim the educating of the general public regarding scientific medicine and the part the medical profession has played in advancing it, thus making this old world of ours a safer place in which to live. It will also instruct our public regarding facts in medicine in a positive and convincing manner, as contrasted with the fads and fallacies which arise from day to day flourish for an hour, but to fade and disappear.

"We believe its effect will be successful in curbing the rapid advance of state medicine and communistic ideas regarding medicine and will also lessen the influence of various cults on our gullible easily influenced public."

The editors comment on the difficulty of getting men to serve on the committee, but the committee itself meets it by providing for a rotation of appointments, each member to serve during five years. This plan is of doubtful value, for it may retain the indifferent and incompetent, and may exclude the qualified. It would probably be better to appoint all the members for one year, and reappoint those who show deep interest in the work.

The Journal reports the first meeting of the committee, at which four bureaus were authorized:

"The Speakers' Bureau would furnish to the medical societies topics to bring before the public; would furnish an already made talk which could be altered by each speaker according to his own ideas and general usage of the subject; would also furnish speakers to local societies when requested and also speakers and topics when requested to the Women's Clubs, Parent Teacher's Association, etc."

One section of the Radio Bureau planned twelve talks, as follows:

"(1) Some Interesting Medical History in Florida.—Edw. Jelks.

"(2) The Florida Medical Association; What It Is and the Value of Its Influence to the State.—Gerry R. Holden.

"(3) The Medical Profession.—G. H. Edwards.

"(4) The Medical Profession—Its Contributions to Charity in the State of Florida.—Ralph N. Greene.

"(5) The Medical Profession—Its Economic Contributions to the State of Florida.—H. C. Dozier.

"(6) The Medical Profession—Its Value to Society.—M. A. Lischkoff.

(*Continued on page 1242—Adv. xxxii*)

If the Patient Were Asked

Atophan

IN RHEUMATOID AFFECTIONS

Atophan is the original Phenylcinchoninic Acid... Trial supply gladly sent on request.

IN rheumatic affections the two most urgent symptoms that impress the patient are pain and ankylosis or inability to use the parts involved. From these he seeks relief.

That is why these manifestations demand first attention. When congestive swelling has disappeared, pain will be relieved and use of the organ will become possible.

ATOPHAN relieves pain, reduces congestion and fever, eliminates uric acid and inhibits its formation — consequently it accomplishes in rheumatic fever, arthritis and gout what constitutes the primary measure of relief.

"It was decided to use as a basis for the program of talks, in so far as they would go, the subject matter as used by the Illinois State Medical Association."

CRIME DETECTION IN WEST VIRGINIA

An editorial in the September number of the *West Virginia Medical Journal* has the following reference to a report of Dr. W. C. Woodward Director of the Bureau of Legal Medicine and Legislation of the American Medical Association

"The committee has recommended, through the A.M.A. board of trustees, that each of the several states provide and maintain the equipment and staff necessary in this work for the service of all communities within its borders.

"Here seems to be another opportunity for the state university at Morgantown. During the past two years West Virginia University has established and maintained, through its various colleges and departments, a number of valuable services to promote the welfare of the state. The college of law, for instance, will draft municipal ordinances and codes for any city or town in West Virginia. The department of journalism has a routine system of news releases sent out regularly to every newspaper in the state. The college of agriculture fathers the extension de-

MEDICAL DEFENSE IN MISSOURI

The following annual report of the Committee on Medical Defense is contained in the July Journal of the Missouri State Medical Association:

"Disposition of Cases

"Cases pending May 1, 1930	14
"Threats pending May 1, 1930	4
"New cases during the year	11
"New threats during the year	6
"Cases settled during the year	5
"Threats which have not developed into suits during the year	1
"Cases pending May 1, 1931	20
"Threats pending May 1, 1931	9
"Financial assistance rendered during the year	$750

"As chairman of this committee I would like to make some remarks about this work which you as delegates should be familiar with and pass on to your colleagues. It would be impossible to go over all the cases, but some I will report.

"We lost two suits, both of them against one doctor, a case of injury to a leg in which it was claimed that he overlooked a fracture. The first suit was decided against the doctor and a verdict for $4,000. Both of these judgments have been appealed. A suit for $20,000 was defeated—a verdict for $1,000 for the defendant. One verdict of $2,500 against the defendant is still in the Court of Appeals. One suit was tried, and on demurrer was dropped. One suit was settled by the insurance company paying $150, and one suit for $100,000 was defeated and the verdict rendered for the defendant. Another suit was settled by the insurance company paying $100.

"Things are changing in this particular department, and instead of getting better they are getting worse. This little report I submit to you is merely a drop in the bucket compared with the number of malpractice suits filed and the number of threats in this State. We only have a very few of them, but when you figure that one company alone has had over 180 cases during this year, and taking into consideration the number of insurance companies in the State, you can imagine what it must amount to. Of course that includes dentists as well."

MEDICAL PRACTICE ACTS IN TENNESSEE

The object of medical practice acts is well discussed in the following editorial from the September number of the Journal of the Tennessee State Medical Association:

"A large number of doctors misunderstand the purpose of the Medical Practice Acts. This is made evident to us by the communications which come to this office concerning violations, quacks, etc.

"The Medical Practice Acts were written for the purpose of protecting the public. They were written for the purpose of giving the public reasonable protection against crooks and quackery in medicine. They were never written for the purpose of protecting doctors against the inroads of quacks.

"When a lay person elects to take some patent medicine in the treatment of an ailment, he is exercising the privileges of his freedom. Such a practice in no way injures the medical profession. If penalty is to be paid, the person who takes the nostrum pays the penalty.

"So long as there are suckers there will be crooks. The burden that rests on the medical profession is that of making our professional services of the highest type possible.

"We injure ourselves and the cause of the profession when we attempt to use the Medical Practice Act to protect the profession of medicine against the influence of some quack. He does not injure us.

"If the science of medicine will not stand up before the public against all sorts of quackery it does not deserve to stand. The facts are it does stand—it will continue to stand."

(*Continued from page 1242—Adv. xxxii*)

partment to aid the farmers of West Virginia. Could not the school of medicine, under Dean John N. Simpson, interest itself in the establishment of a criminologic institute? We feel that it is an idea well worth thinking about, and we serve only as the middle-man to pass the idea from the American Medical Association to West Virginia University."

REPRINTS FROM THE KENTUCKY JOURNAL

Practically every author of an article in a medical journal orders reprints of his paper. The policy of the *Kentucky Medical Journal* is outlined in its August issue, as follows:—

"Immediately upon the appearance of an author's article in the Journal there is mailed a yellow reprint order by the Times-Journal Publishing Company, which contains the prices of from 100 to 1,000 reprints, with the notation that the type of this article will be kept until a certain date, usually about two weeks after the article has appeared in the Journal. The type is then 'pied' and melted, and is ready to use again for the next issue of the Journal. Many of our contributors have disregarded this reprint order entirely, until they have received requests for reprints, not only from the physicians in Kentucky but from many states in the Union. As this Journal has courtesy exchange with all of the State Journals, as well as many of the special Journals, it is not unusual in an especially interesting article, for the author to receive requests from ten different states,—then suddenly he realizes that he has not ordered reprints and must go to the expense of purchasing the Journal at 50c per copy, and is frequently not able to get all the Journals he requests, when for $2.00 he could have received 100 reprints.

"These reprint orders should be filled out immediately, and as is stated in the circular, mailed direct to the Times-Journal Publishing Company, Bowling Green."

SANITARIUM OR PRIVATE HOSPITAL

There is a wonderful chance to establish a *Sanitarium* or *Private Hospital* in the suburbs of a town of North New Jersey, 25 miles from N. Y. City. Has 9 acres of landscaped grounds with three buildings having rooms for staff nurses, and fifty or more patients in single rooms—all buildings *completely furnished* in bedrooms, dining rooms, parlors, kitchen, etc (almost new). Full particulars as to why this place is to be sold. Address *Swift Realty Co.*, 196 Market St., Newark, N. J.

Vermont Healthatorium

Beautiful residence ideally situated in the most picturesque village of Vermont. Special care of the Convalescents and Invalids. Physician in attendance at all times. Opening July 1. Write or 'phone, Dr. W. J. McNamara, North Park Place, Fair Haven, Vt. Tel. Fair Haven —I.

SANITARIUMS—FOR SALE

We have a number fully equipped, some partially so, and properties that can be made suitable; New York, New Jersey, Connecticut. Send for list and give number of rooms wanted for patients (approximately), also location desired. Address Swift Realty Co., 196 Market Street, Newark, N. J.

FOR SALE—Large selection desks, chairs, tables, files, upholstered leather sets, bookcases, storage cabinets, card indices, lamps, suitable professional offices; new and used. Driver Desk Company, 6 East 33d, BOgardus 4-1952 or 5054.

EAR, NOSE AND THROAT MAN: (Gentile) of high standing, having 20 years experience, would like to work one day a week in some town within 100 miles of Manhattan. The courtesy of a good local hospital is essential. Address Box 159, c/o N. Y. STATE JOURNAL OF MEDICINE.

IDEAL MODERN BRICK HOUSE: 9 rooms; 2 sun parlors; large reception foyer; 2 baths; lavatory; 2 staircases; oil burner; open fireplace; garage; large landscaped grounds; centrally located; exclusive apartment houses; fast growing community. Reasonable. Meyer, 144-32 Northern Boulevard, Flushing, N. Y.

NOTICE TO PHYSICIANS—SANITARIUMS: Trained nurse, broad experience, returning to California, will assist lady, convalescent or elderly, for expenses; or accompany male patient and family as secretary; experienced shorthand, own typewriter. Moderate fee if needed after arrival. Credentials New York, California. Address Box 160, c/o N. Y. STATE JOURNAL OF MEDICINE.

ARTIFICIALLY FED INFANTS

"The nearer the milk administered to the artificially fed infant approaches *human breast milk in composition* and sterility, the nearer the artificially fed infant approaches in its general resistance and condition that of normal nurslings."

This statement written by a member of the White House Conference presents accurately the idea back of S.M.A., an infant food developed at the Babies and Children's Hospital of Cleveland, Ohio. S.M.A. is regarded by many physicians to be the closest approximation to mothers' milk in existence.

It resembles breast milk, having the same percentage composition and in addition, the same buffer value, depression of freezing point, specific gravity, hydrogen ion concentration and caloric value. It is also interesting to note that the fat in S.M.A. has the same character numbers as breast milk fat, such as Polenske, Iodine, Reichert Meissel, Saponification, Melting Point and Refractive Index. Sufficient cod liver oil is incorporated in this fat to make it anti-rachitic.

Like breast milk, S.M.A. is used without modification for the normal full term infant with excellent result in most cases.

The tuberculin tested cow's milk used as a basis for the production of S.M.A. is under the strict supervision of both Cleveland and Chicago Boards of Health.

Special Food for Premature Infants

For premature infants, and to correct diarrhea and malnutrition, Protein S.M.A. (Acidulated) is recommended. This is a special form of S.M.A. high in protein and low in fat and carbohydrate, with a relatively high acidity. The same anti-rachitic fat is present supplying vitamin "D" and it contains enough lemon juice to make it anti-scorbutic as well.

Develops Non-Allergic Milk

For infants, children and adults sensitive to milk protein, the S.M.A. Corporation has produced a non-allergic cow's milk (SMACO 300). Excellent results have been reported.—See page xxv.—*Adv.*

A STUDY IN PEDIATRIC RHEUMATIC PROPHYLAXIS

Podolsky and Goldstein—Medical Journal and Record, Vol. CXXXI, No. 3, August 5th, 1931, page 139.

Along the lines suggested by Lee in his study of the prophylactic effect of acetylsalicylic acid in the prevention of the rheumatic syndrome in pediatric practice, the authors administered a combination of acetylsalicylic acid and magnesium to their series. In the group of nine potentially rheumatic children controlled by seven similar cases they found that acetylsalicyl acid probably exerts a prophylactic influence upon the rheumatic syndrome in children. They further found that acetylsalicylic acid with magnesium appears to be equivalent in such use grain for grain to acetylsalicylic acid alone. Calco Chemical Co., Inc., Bound Brook, N. J. VOL. 31, NO. 20 NEW YORK, N. Y. OCTOBER 15, 1931

THE PRESENT STATUS OF POST-OPERATIVE TREATMENT

By C. V. BURT, M.D., NEW YORK, N. Y.

From the New York Post Graduate Medical School and Hospital, New York City.

IN this paper I have made an effort to briefly summarize the immediate post-operative treatment, and to present practical procedures for the effective management of the complications that most commonly arise following operative interference.

Post-operative procedures for uncomplicated cases: It is no longer considered necessary to maintain the patient in a recumbent position or to withhold food for several days. As soon as the patient has reacted from his general anesthetic, he is placed in a sitting or semi-sitting position, and allowed to move about freely. In fact, we make it a practice to turn our patients from side to side every one to two hours. He is further permitted to take water in half ounce quantities in increasing amounts as soon as he has reacted from the anesthetic. The next morning he is given weak tea. Provided there have been no contraindicating sequellæ up to the morning or noon of the first day after the operation, we add full fluids, gruels, cereals, milk toast or other light foods. On the second day, potatoes, pureed vegetables, and, in short, everything except meat, are permitted. On the third day we allow a full diet. We feel that most patients may have practically anything they want to eat when they want it, except in gastro-intestinal anastomoses.

A water balance is maintained by the administration of 6 oz. of saline or tap water as retention enemas every four hours, or proctoclyses of 500 cc. of 10% dextrose in saline or tap water for the first 24 to 48 hours. If the patient is particularly dehydrated, hypodermoclyses of 1500 cc. of 5% dextrose in normal saline once or twice a day are given. These are discontinued as soon as the patient is retaining fluids by mouth.

Comfort is maintained by the hypodermic administration of morphine sulphate gr. 1/6 to 1/4 or pantopon gr. 1/4 every four hours as long as necessary. Morphine sulphate gr. 1/6 together with 2 cc. of 50% magnesium sulphate sometimes is very effective when the opiates alone fail. A combination of codeine sulphate gr. i with pyramidon gr. x makes a very effective preparation for less severe discomfort. After the second or third night, it is usually possible to obtain comfort with allonal, luminal, chloral hydrate or bromides.

In the uncomplicated cases, on the night of the second or third post-operative day, the patient is given a cathartic and on the morning of the third or fourth day, an enema. Where the site of the operation is above the colon, an enema may be given immediately after the operation, if desired. When the colon has been the site of an operation, as in resections of the cecum or sigmoid, one or two glycerine suppositories may be used very effectively.

Abdominal distention and gas pains are usually effectively relieved by the administration of soap suds, milk and molasses or alum (1 oz. to the pint of water) enemas. The injection of 1 cc. of pituitrin every 2 or 3 hours, with a rectal tube in position, very frequently provides relief from distention and gas pains. This is particularly effective where enemas have failed to produce desirable results. Where the distention is largely epigastric, the introduction of the small tube into the stomach, with evacuation of the fluid and gaseous contents very often provides great relief. Turning the patient on his abdomen helps considerably in the expulsion of gas. Fruit juices should be withheld for 3 or 4 days.

Not infrequently we are confronted with what we might call "nervous vomiting." In spite of the fact that these patients look well, present no distention and experience no undue amount of pain, they continue to vomit small quantities of clear or light green fluid. The insistence upon their eating solid foods and the administration of chloral hydrate gr. xx and sodium bromide gr. 50 by rectum every four hours will usually clear them up in the course of 24 hours. Often the ingestion of solid foods will serve the purpose.

Following spinal anesthesia, we place the patients on the transfer stretcher with the foot of the stretcher elevated 10 inches. We place them in bed with the foot of the bed elevated on 10

inch shock blocks, and keep them so for 12 hours. We give them water and other fluids immediately, even during the operation in some instances.

In cases of gastric resection, gastro-enterostomy and pyloroplasty, it is of considerable value to lavage the stomach every eight hours for the first 24 hours after the operation, in order to maintain alimentary tranquillity. These cases are given one to three ounces of water every hour, beginning two hours after they react from the anesthetic. Additional fluids are supplied by hypodermoclyses, proctoclyses and infusions where necessary. The water alone is continued orally until the second day, when fruit juices and sugar are added. On the third day, milk, gruels, thin cereals and pureed vegetables are given, and on the fourth day, solid foods are permitted.

It is very important to allow the family to see the patient immediately following the operation, in order that they may be reassured that the patient withstood the operative procedure. Visitors may be allowed up to the point of fatigue. They need not be restricted except in such conditions as hyperthyroidism.

Following abdominal operations, the dressings are not disturbed until the eighth day, unless the patient complains of pain in the wound or there is a temperature rise, thus indicating a wound infection. Ordinarily we remove skin and retention sutures on the eighth day, except in cases of carcinoma or debilitated or very obese patients, when the sutures are left in place until the 10th or 12th day. Cigarette drains are shortened on the 3rd day and entirely removed on the 4th or 5th day. Our patients are allowed out of bed on the 8th or 9th day and home on the 10th to the 12th day.

Post-Operative Complications and Treatment

Among the more important post-operative complications, and those which cause the surgeon the greatest concern and the patient the most discomfort are: shock, acute gastric dilatation, severe post-operative hemorrhage, leakage from imperfect intestinal anastomoses, sepsis, phlebitis, embolus, massive collapse of the lung, hiccough, starvation, dehydration, urinary suppression, acidosis and alkalosis. These require prompt and persistent treatment.

Shock

With the onset of shock, there is a collapse to a varying degree of the circulatory mechanism, the pulse rate rises, the blood pressure and temperature fall, cerebral anemia develops, and, as Heyd points out, hepatic detoxification is diminished. Of the measures most often employed to combat shock, Clark position or elevation of the feet, and the application of external heat rank uppermost. Practically, the most effective means of combating the lowered arterial tension and increased pulse rate is by the intravenous introduction of fluid. The fluid of choice is blood, though 800 to 1,000 cc. of normal saline or 10% dextrose in saline may be used with dramatic effect. Hot rectal instillations, such as black coffee, may be of value. Hypodermic stimulation, as caffein sodium benzoate (grs. viiss) or adrenalin may be used with some benefit.

Acute Gastric Dilatation and Dehydration

Within the first 24 hours after the operation, many patients become fatigued and nervous, and begin to hiccough, regurgitate or "spitup" small quantities of fluid. For several hours they have been unable to take or retain sufficient fluids orally, and are, as a rule, suffering from dehydration and acute toxemia. Frequently they present an acute onset of projectile vomiting of large quantities of fluid varying in color through white, green, yellow, brown and black, more commonly black. These are the most reliable indicators we have of an approaching acute gastric dilatation.

As soon as the patient presents any evidence of an impending acute gastric dilatation, we make it a rule to (1) deflate and empty the stomach and maintain it in a state of "rest," and (2) supply the system with adequate fluids.

1. *Gastric rest:* In order to place the stomach at rest and prevent the deleterious effect of the jejunal reflux, the stomach may be maintained in an empty state by the intra-gastric retention of a Levine tube, which is a soft rubber tube the size of a No. 16 French catheter. It is introduced through one of the nasal passages, after lubricating the tip of it, to the posterior pharyngeal wall. The patient is then permitted to drink water slowly. As he swallows, the tube is gently fed into the stomach, with practically no discomfort. The gaseous and fluid contents of the stomach are easily and quickly withdrawn through a syringe attached to the tube. If the quantity of fluid obtained is 15 ounces or more, or is very dark or foul, the tube is left in the stomach, and it is attached to the cheek by means of adhesive plaster. The free end of the tube is connected with a bottle attached to the side of the bed. The patient is then permitted to drink fluids as he desires them, or they may be introduced through the tube by means of a syringe.

Through syphonage, the stomach may be kept entirely empty or the tube may be clamped off any desired number of hours. Ordinarily, at first we allow the contents to run off for a few hours, in order to thoroughly empty the stomach and relieve it of the jejunal reflux. When the condition of the patient permits, we allow the contents to flow only during alternate hours. Gradually, we reduce the time during which the contents may escape until the patient retains all fluids, at which time the tube is clamped off constantly or is removed. The retention of the tube permits the

patient to satisfy his sensory and subjective sensations of thirst without endangering gastric tranquillity. This tube frequently is retained in the stomach for days. After the first 24 hours, there is practically no discomfort to the patient. Frequently he is fed through this tube. So great is the relief it provides that the patients not infrequently ask for its reintroduction.

It is very important to know how much of the fluid administered orally the patient is retaining. The evacuating capacity of the stomach provides this. We can determine this roughly by recording the intake by mouth and the output through the Levine tube. However, a more accurate estimation is desirable and available. The stomach is completely emptied through the tube, and at a certain time six ounces of water are given by mouth or through the tube, which is then clamped off. After a given period, say one hour, the contents of the stomach are aspirated. The difference between the amount given and the fluid obtained through aspiration represents the amount of fluid not exacuated by the stomach, or any excess over that given represents the reflux from the intestine.

Occasionally a surgeon is confronted with intragastric hemorrhage from an insecure gastroenterostomy. It is difficult to decide whether or not to reopen the abdomen to establish hemostasis. Aspiration of the gastric contents through the Levine tube at a definite time, and a repetition of this at stated intervals will often prove a very valuable aid in determining the amount of hemorrhage over a given period of time. This evacuation of the contents of the stomach also tends to check the hemorrhage.

2. *Fluids* should be supplied in every available manner, and in such form as to meet the desired requirements. We are concerned here principally with the use of normal and hypertonic saline solutions and dextrose in normal saline.

a. *Hypodermoclyses* meet all of the ordinary requirements in the post-operative cases. However, where the patient is in a moderate or marked degree of shock, and the pulse is of poor quality, or where there is acute toxemia with paralytic ileus, these sub-cutaneous fluids are absorbed very poorly. Under these circumstances, we much prefer to give fluids and carbohydrates intravenously, either as continuous venoclyses or separate infusions. Following prolonged operations or those of any severity, we usually administer 1,500 to 2,000 cc. of 5% dextrose in normal saline under the skin immediately after the patient returns to bed. A similar hypodermoclysis may be repeated once or twice during the next 24 hours. Usually by this time the patient is taking fluids by mouth, and the administration through other routes may be discontinued. After the patient reacts from the anesthetic, subsequent clyses are very painful, owing to distention of the tissues. This pain can be relieved to a considerable extent by injecting 5 cc. of a 2% solution of novocain into the delivery tube at the commencement of the clysis, and by adding 5 to 10 cc. of 2% novocain to the fluid in the container. The skin should be infiltrated with novocain prior to the insertion of the clysis needles.

b. *Proctoclyses* of 500 cc. of 10% dextrose in normal saline (0.9%) or tap water may be given every eight hours, in addition to either clyses or infusions, or a continuous Murphy drip may be instituted. These are usually poorly tolerated by the patients after the first one or two are given, and the percentage of absorption of the nutritive and medicated ingredients is small. Retention enemas of 6 or 8 oz. of normal saline or 10% dextrose solution every four hours are much less irritating, and are tolerated for a much greater length of time. Lugol's solution or other medication may be given with these instillations.

c. *Intravenous therapy* represents the introduction directly into the blood stream of physiologic and therapeutic solutions, which must be sterile, compatible with the blood and fulfill the indications desired.

The objective in the use of intravenous fluids is to provide fluid volume to increase the vascular tension and reduce dehydration, combat infection, and to supply food, chlorides and antiketogenic substances. The direct delivery of fluid into the veins inhibits peristalsis, places the alimentary tract at rest and renders the patient independent of his intestinal tract for several days, which is particularly valuable in cases of intestinal anastomoses.

The solution "par excellence" is whole blood. For economic reasons and because of the necessity of meeting the indications as quickly as possible, it is frequently not expedient to administer blood. Either normal saline, acacia, distilled water, or 5% or 10% dextrose in distilled water or normal saline may be used. We prefer the use of 10% dextrose in normal saline.

Any intravenous medications indicated, as insulin, digitalis, sodium iodide and calcium chloride, may be added to these solutions by injecting them through the delivery tube by means of a needle and syringe.

Mode of administration: The fluid is held in a suitable container, usually a glass bottle of 1,000 cc. capacity preferably with an attached mechanism for the maintenance of a constant temperature. Hot water bottles may be adjusted to the container so as to maintain the desirable temperature. The fluid should be delivered into the vein at approximately 100° F., which necessitates the maintenance of the fluid in the container at 120 to 130° F., since much heat is lost through the delivery tube. The container is suspended three or four feet above the level of introduction into the body, and is connected with a suitable needle by means of rubber tubing. The needle may be of any suitable size, but the ordinary 15 to 17

gauge blood chemistry needle is quite convenient. For continuous administration over a period of several days, a gold or silver plated canula is advisable. The ordinary needles do not remain patent for a sufficient length of time. A visible rectal dripper connected into the delivery system aids materially in the continuous administration of the fluid. Any superficial vein may be selected, but the median cubital or cephalic veins are most conveniently used. Those of the forearm and hand may be found useful.

The fluid may be introduced intermittently or continuously. At any rate the flow should be slow, particularly when a cardiac condition is known to exist. The sudden collapse of the circulatory mechanism, such as is experienced in a rapid loss of a large quantity of blood or a marked degree of shock, as following some cases of spinal anesthesia, brain surgical procedures or other conditions in which the vascular tension is extremely low, are the only indications for a rapid delivery of fluids intravenously.

Ordinarily fluids, other than blood, may be introduced at the rate of 1,000 cc. per ½ hour with a repetition two or three times during a 24 hour period. Frequently we give 1,000 cc. of 5 or 10% dextrose solution in normal saline intravenously at 8 hourly intervals when the condition of the patient is serious and the delivery of fluids into the system is imperative. At this rate the danger of overloading the heart is slight and the percentage of chills and temperature reactions is extremely small. Hendon[1] recommends a continuous venoclysis of 10% dextrose solution, given at the rate of 200 cc. per hour, or a range of between 4,000 and 5,000 cc. of fluid in 24 hours for an adult patient. In general, our tendency is to reserve intravenous fluids for rather urgent indications.

Infusions are far more comfortable for the patients than are the hypodermoclyses, they supply food and fluids directly into the vascular system, and, through distention of the blood vessels, produce a stimulation of the vital centers, which brings about an improvement in the patient's general condition. Very rarely have we seen any reactions which we thought were due to cardiac embarrassment as a result of the introduction of too much fluid into the vascular system or a too rapid delivery of the fluid.

The causes of chills, temperature elevations and other unpleasant reactions following infusions have been thoroughly studied. No definite conclusions have been reached. When we have kept the solutions in the containers at 120 to 130° F., these reactions have been so rare that we believe the delivery temperature plays a very important role in the prevention of these unpleasant conditions. Rademaker,[2] following a series of recent experiments, suggested that these reactions were due to alkaline impurities in the solutions.

Hendon has observed from clinical experience that about 200 cc. of fluid per hour, in the form of a continuous infusion, or 4,000 to 5,000 cc. of 10% dextrose solution per 24 hours approximately meets the physiologic requirements of the adult patient. In cases of septic infections, he found that one pound of dextrose a day could be cared for without sugar appearing in the urine. He states further that under these circumstances his patients were free from chills and sudden temperature reactions. At the above rate, the blood sugar was never more than 200, and it is said to return to normal within three hours. In 95% of Hendon's cases, the red blood cell count was increased following these venoclyses. With continuous infusion, using a gold or silver canula, Hendon found that a vessel would remain sufficiently patent for an average period of five days. The longest period of continuous administration was accomplished by Strickler who, by changing veins, kept the flow going for 21 days.

Hiccough

Hiccough may be an alarming, or even a fatal condition following operative procedures. Its etiology is not known. At first, attacks of singultus may appear for only a few seconds at a time, and gradually become more frequent and more prolonged until the patient is hiccoughing almost constantly. If this is permitted to continue, extreme exhaustion will result. Occasionally, persistent hiccoughing seems to precipitate a fatal termination.

There is no completely satisfactory treatment for this condition. In our hands the inhalation of a mixture of 10 to 30% carbon dioxide in oxygen has proved to be the most effective means we have of controlling hiccoughs. This is administered through a rebreathing bag, which is connected to a tank of the carbon dioxide mixture. These are kept in the patient's room, and as soon as he begins to hiccough he is immediately started rebreathing this mixture. It is continued until the respiratory excursion is marked, i.e., the inspiratory and expiratory phases are markedly prolonged and very deep, resulting in a greatly increased absorption of CO_2 and O_2. The respiratory rate is only slightly increased. Using this mixture and method of administration, one is usually able to stop the hiccoughing in from ½ to one minute. It is very likely that it will recur, and it is necessary to repeat the rebreathing procedure.

The administration of the carbon dioxide should be discontinued if the patient shows any signs of twitching of the fingers, forcible motion of the head or other indications of a convulsion, which sometimes occurs as a toxic manifestation during the inhalation.

Before the carbon dioxide is administered, the patient should be given any desired food or fluids, the shades should be drawn, and the room made absolutely quiet, so that it is not necessary

for the patient to move after the hiccoughs have stopped. Any motion of the patient or disturbance in the room are very likely to cause a recurrence.

A distended bladder is frequently a cause of hiccough, and an evacuation of the bladder contents will serve to relieve this symptom. In many instances relief has been provided by lavaging the stomach with alkaline solutions. Among the other preparations frequently used are: benzyl benzoate, Hoffman's anodyne, chloretone, belladonna, atropin, Tr. of valerian, Tr. of capsicum, purgatives, adrenalin, and, perhaps the most effective of all of these, opiates, chloral hydrate and bromides. It is very important to maintain the patient in a state of comfort and relaxation.

Urinary Suppression

Suppression of urine is invariably a serious symptom and calls for prompt treatment. It is especially liable to occur in patients in whom there is pre-existing kidney damage, for example, chronic nephritis. Not infrequently, following an operative procedure, a patient will manifest a partial or complete suppression of urine, which may be considered to exist when the output is 200 cc. or less in a 24 hour period. If it is 800 cc. or more we need not be concerned about a suppression.

It is said that a total suppression may be present for 10 to 14 days before death occurs, but a fatal termination from cardiac or respiratory embarrassment frequently occurs before this time. When anuria itself does not cause a demise, the accumulated toxic by-products act adversely upon the other organs, particularly the liver, and reduce their efficiency. Anuria may, therefore, be a primary or secondary cause of death.

Acidosis is almost, if not always, present when there is urinary suppression, and hence alkalies can be given in fairly large amounts without danger of producing alkalosis and tetany. The practice of giving alkalies without previous knowledge of the bicarbonate content of the blood plasma cannot be too strongly condemned.

There is experimental evidence to show that anuria may be associated with either an abnormally high or low plasma bicarbonate. Experience and experimental data indicate that the excretion of urine begins when the alkali reserve reaches a normal level, and that when the alkali reserve is maintained at a normal level, post-operative complications do not develop in patients with kidney damage where they might be reasonably expected. The pre-operative administration of alkalies will establish a normal alkali reserve and should prevent much of the post-operative suppression of urine.

The treatment of urinary suppression consists in stimulation of the kidneys and in promotion of elimination of waste products through the skin and bowels by means of hot packs, diaphoretics and purges. Counter-irritation to the kidney in the form of hot applications and warm colonic irrigations may be of value. It is extremely important to relieve any existing dehydration and acid-base imbalance.

Osman[5] believes that alkalinization of the system is very important in urinary suppression. He states that a mixture containing 30 grains each of potassium citrate and sodium bicarbonate may be given at hourly or two hourly intervals, or in case coma exists, an equivalent of a 3% solution of this mixture may be given by rectum. It is seldom necessary to give this intravenously. The difficulty of sterilizing sodium bicarbonate solutions for intravenous use makes this method very complex.

He says further that the administration of alkalies should be continued in these quantities until diuresis commences and reaches 15 ounces in 24 hours, at which time the dosage should be reduced, say one-third, but not withdrawn. If there is a decrease in the urinary output, the dosage should be increased. A sufficient dosage to maintain a satisfactory diuresis should be continued. Upon withdrawal of the alkalies, anuria is apt to recur and be extremely resistant to treatment.

The chief danger in the administration of alkalies is the development of alkalosis and tetany. When alkalies are being given, repeated determinations of the CO_2 combining power of the blood should be made.

Fluids should be given in adequate amounts through all channels, not less than, say, 2,000 cc. per 24 hours. In our hands, the intravenous administration of 1,000 cc. of 10% dextrose in normal saline two or three times in 24 hours has been the most effective diuretic we have used. Caffein sodium benzoate grs. viiss hypodermically every four hours has often proved of value in promoting kidney excretion. Usually we administer it in conjunction with the infusions. Alkalinization is undoubtedly an important factor in the treatment of partial or complete suppression of urine.

Septicemia

Not infrequently following the release of abdominal adhesions and other general surgical procedures, the patient's temperature will suddenly rise to 103 to 105° F., and begin to run a typically septic course. The patient appears acutely ill, the pulse and respiratory rates are increased, and there is an expiratory grunt. There may be pains in the legs, chest or other parts of the body suggesting phlebitis or multiple pulmonary emboli. The general reaction of the patient and the facies suggest a pneumonic process, but a thorough physical examination fails to reveal anything to account for the temperature, pulse and respiratory variations.

Occasionally agglutination reactions will demonstrate the existence of Malta fever. Much more frequently, however, a blood culture will show the presence of streptococci, B. coli or other vicious organisms in the blood stream.

As soon as a hemic infection is found to be present, prompt and persistent treatment should be provided. Blood cultures should be taken every two days. The type of organism present should be definitely determined, if possible. If it is a streptococcus and within a group for which a specific antiserum has been prepared, this serum should be given intramuscularly in doses of 5,000 units every day. If no specific antiserum has been prepared, we are unable to accomplish very much with the serum treatment. In the absence of a better means of treatment, we may give a like dose of anti-scarletinal serum every day. Further general therapy may be attempted by the intra-muscular injection of 5 cc. of spleen extract every day, as a stimulant to the hematopoetic system.

Bacteriophage is highly specific and by direct contact causes a lysis of the organisms, for which it is specific. Within the streptococcus group it is in the experimental stage and affords little hope for relief at the present time. However, in the B. coli and staphylococcus aureus and to a less extent in the staphylococcus albus group, it is very effective, and a sufficient number of strains of bacteriophage has been prepared to enable one to treat these infections quite effectively.

For staphylococcus aureus infections, we give 5 cc. of the bacteriophage intravenously every half hour until 40 to 60 cc. are given. If a chill, high temperature or other unpleasant reactions occur, we discontinue its use. We believe that the intravenous administration is more effective, though the intramuscular or subcutaneous injection in somewhat larger doses may be used. In the B. coli group, smaller doses are required.

We feel that repeated small transfusion and infusions of dextrose in normal saline are of great value. We prefer to administer 500 to 750 cc. of 10% dextrose in normal saline twice a day, and 350 cc. of whole blood every two or three days. It is of the utmost importance to maintain an adequate fluid and chloride supply, and to provide a high caloric intake. These patients should be encouraged to take as much food and fluids as possible by mouth.

Acidosis

Acidosis is a condition in which the alkali reserve of the blood plasma is reduced. Acidosis may be nephritic or ketogenic in origin. The majority of these cases are of nephritic origin. The chemical states leading either to acidosis or alkalosis are dependent upon dehydration, vomiting, diarrhea, anoxemia, incomplete dextrose oxidation or circulatory or renal insufficiency, and, as Heyd[4] points out, to hepatic dysfunction.

Marriott & Howland[5] ascribed the acidosis of nephritis to the failure of the kidneys to excrete acid phosphates, which make up 90% of the phosphates of the urine. These authors also noticed in a nephritic acidosis a decrease in the blood serum calcium, and that when the calcium dropped to 7 mgm. per 100 cc. or less, this decrease was accompanied by muscular spasms or distinct convulsions. Bandler and Killian[6] have called attention to a reciprocal relationship between the inorganic phosphorus and calcium—as the inorganic phosphorus decreases the calcium shows a return toward the normal. They suggest that the fatal outcome of the nephritic acidosis may be due to a reduction of the blood serum calcium to less than 7 mgm. per 100 cc. with death in convulsions, a termination in nephritis frequently mislabeled "uremia." Hence it is important in handling a nephritic acidosis to determine the carbon dioxide combining power and the inorganic phosphorus and calcium content of the blood plasma. The CO_2 combining power of the blood can be influenced by the administration of alkalies, but it is evident that these do not completely inhibit the tendency to acidosis, except insofar as alkalies may influence diuresis and hence promote the excretion of the retained phosphates.

It has been shown that calcium administered in any form causes an increased elimination of phosphates, chiefly by way of the intestines. The converse is also true. This suggests that the administration of calcium should prove of definite value in the treatment of nephritic acidosis, as well as the spastic or convulsive stages of nephritis, frequently called "uremia."

The acidosis of ketogenesis is thought to be due to the incomplete oxidation of fats as a result of the improper metabolism of carbohydrates, resulting in the accumulation in the system of ketone bodies.

Heyd and Killian[7] state that the diminution of the CO_2 combining power below 50 volumes per cent indicates a decrease in the alkali reserve and the onset of acidosis. When the CO_2 combining power drops to 40, a moderate acidosis is present; to 30 a severe acidosis; and to 20 an acidosis that will probably prove fatal (see Fig. 1).

The principal clinical manifestations of acidosis are: dehydration, vomiting, dyspnea with long sighing respirations, acetone breath and drowsiness, lapsing into coma. It must be recalled that from the clinical signs alone it is extremely difficult to differentiate between acidosis and alkalosis. However, vomiting is more marked in alkalosis, and acetone breath is present only in acidosis. The final diagnosis depends upon the presence of acetone bodies in the freshly drawn urine and a decrease of carbon dioxide in the blood.

Acidosis was formerly much more prevalent when it was the custom to starve and dehydrate patients for 24 to 48 hours prior to operation.

Much can be done in the preoperative period to prevent this by forcing fluids orally, by rectum, in some instances subcutaneously and even intravenously In the presence of jaundice or tumors of the large bowel or those involving the pylorus, or other conditions in which the fluid absorption has been small, we make it a practice for 24 to 48 hours before the operation to force fluids by mouth, give retention enemas of 8 oz of saline or tap water every four hours, and in many instances within a few hours prior to the operation to give a hypodermoclysis of 1,500 c c of dextrose in normal saline

The rationale in the treatment of ketogenic acidosis is based upon the assumption that this condition is the result of incomplete metabolism of fat, as a consequence of the lack of carbohydrate for "fats burn in a flame of carbohydrate" The concurrent dehydration also must be relieved

Depending upon the severity of the acidosis carbohydrate may be given orally, subcutaneously or intravenously We prefer the intravenous route, using 10% dextrose in normal saline, giving 1,000 cc at a time and repeating it two or three times in 24 hours Dextrose in this form acts almost as a specific through its antiketogenic properties, in that it supplies carbohydrate in a readily oxidizable form which permits the complete reduction of fatty acids It acts further as a diuretic, which assists in the excretion of phosphates and toxic by products of metabolism

The methods of treatment of acidosis of nephritis are based upon the promotion of kidney excretion, as well as relief from dehydration and acid-base imbalance This is most effectively accomplished by the intravenous introduction of fluids, preferably dextrose in normal saline, as in the treatment of ketogenic acidosis The more rapid the introduction of the dextrose solution, the greater the diuretic effect and the less the dextrose retention and metabolism

The alkalinity of the system may be adjusted so as to promote diuresis, and the acidosis may be reduced by the oral or rectal administration of bicarbonate of soda The dosage of alkali in the form of sodium bicarbonate is calculated according to the formula of Palmer and van Slyke, that is, 0 5 gram of sodium bicarbonate will elevate the CO_2 combining power of the blood plasma one volume per cent for each 42 pounds of body weight Giving sodium bicarbonate beyond this limit elevates the alkali of the blood plasma above the upper normal level and produces an uncompensated alkalosis, which may lead to death in tetany Concurrent with the administration of alkalies, the CO_2 combining power of the blood should be determined at least once in 24 hours

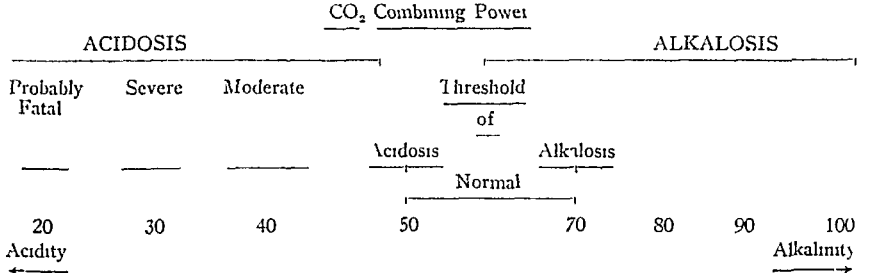

FIGURE 1

An increase in the CO_2 combining power toward 80 volumes per cent indicates an alkalosis, the reverse an acidosis (after Killian)

ALKALOSIS—TETANY

Alkalosis presents a clinical picture of shock plus intestinal obstruction It is only within recent years that attention has been directed to alkalosis as an etiological factor in the occurrence of otherwise baffling deaths It has been frequently confused with acidosis, acute paralytic ileus, intestinal obstruction and acute gastric dilatation

Alkalosis results from an acid-base imbalance, in which there is either an increase in the base or a decrease in the acid radical of the blood This usually results from persistent vomiting, with a rapid loss of chlorine in the form of hydrochloric acid Not infrequently, however it follows the indiscriminate use of alkalies in the pre operative and post operative periods Occasionally a patient is converted from an acidosis into an alkalosis by frequent gastric lavages with sodium bicarbonate solutions

With the onset of alkalosis, the patient may first begin to hiccough, he becomes nauseated, "spits up" and soon vomits He is unable to retain anything in his stomach At first the vomiting is accompanied by retching but later the fluid, which is green, brown or more commonly black, spills out of the mouth in large quantities The intestinal tract soon ceases to function and the

abdomen becomes considerably distended. There is present intense toxemia and marked dehydration. The patient appears acutely ill, his cheeks are sunken, his extremities are cold and clammy and his temperature is normal or subnormal, though he insists that he feels fine.

The diagnosis of this condition depends upon first the consideration of its presence as an etiological factor, and, in the last analysis, upon the characteristic blood chemistry findings, which show a rise in the nonprotein nitrogen (25-35 mgm. per 100 cc. of blood), a fall in the blood chlorides (0.45 to 0.50%), and an increase in the CO_2 combining power of the blood (50-70 volumes per cent). In alkalosis the alkali reserve is definitely increased above the normal, and the CO_2 combining power varies between 70 and 100 volumes per cent.

The general principles of treatment of alkalosis are based upon supplying adequate fluids, chlorides and dextrose or other readily oxidizable carbohydrate, and the promotion of renal excretion, elimination through the intestines, and relief of gastric dilatation and duodenal reflux, the latter two of which are discussed in detail under "acute gastric dilatation."

We believe that the requirements for the control of alkalosis, dehydration, starvation and suppression of urine are adequately met by the intravenous administration of 1,000 cc. of 10% dextrose in normal saline twice and 1,000 cc. of 2% saline in 24 hours, given eight hours apart. A similar amount of 5% dextrose in normal saline may be given, though with much more discomfort, by hypodermoclyses in case the intravenous administration seems inadvisable. In addition, one may give retention enemas of 6 oz. of saline or tap water every four hours, or a 10% solution of dextrose in normal saline or tap water as a continuous rectal drip or a 500 cc. Murphy drip of this fluid every eight hours.

The function of the dextrose is that of a diuretic. The advantage of the hypertonic saline is that it supplies a large amount of chloride with a moderate volume of fluids. The principal disadvantage of the hypertonic saline is that it causes thrombosis of the veins. Some of these cases that are receiving large quantities of fluids intravenously show edema of the feet and hands, and it is possible that this is due to the amount of sodium chloride in some instances and not necessarily to the amount of water given.

The acid salts, such as ammonium chloride and acid phosphates, have a tendency to reduce the alkali balance. The acid phosphate is given in doses of 4 cc. every 2 or 3 hours. If vomiting prevents its oral administration, it should be given by rectum, using twice this dose. These salts are so quickly neutralized that they accomplish little toward the relief from the alkalosis.

Insulin may be given with the dextrose solution at the rate of one unit of U-20 insulin for each 1½ gm. of dextrose. Not more than ½ of the carbohydrate given intravenously should be neutralized with insulin. Though the insulin accelerates the rate of metabolism of the sugar and the oxidation of the acetone bodies, it is not necessary except in cases of primary diabetes or hyperglycemia.

Tetany when present is almost pathognomonic of alkalosis. It is of serious import and requires immediate treatment. It results from a diminished available calcium in the blood stream. Snell[8] states that about 50% of the blood calcium is in combination with the serum protein and cannot be removed by diffusion. He states further that there is a diffusible portion, which probably protects the organism against tetany, and that it is upon the diffusible or available calcium that the parathyroid hormone exerts its effect. The parathyroid hormone is believed to be a calcium mobilizer. In case of deficiency of calcium, more calcium is drawn from the skeleton by its action.

Collip[9] has prepared an extract from the parathyroid glands of animals, which has proved very effectual in not only controlling the symptoms of tetany but in causing an elevation of calcium in the blood serum in normal animals. This parathyroid extract has been used clinically with good results in cases of tetany. It is given in doses of 20 to 30 units (1-1½ cc.) and, if necessary, is repeated 2 or 3 times in the first 24 hours. The doses are then diminished according to the condition of the patient. Hypercalcemia may be fatal unless the parathyroid hormone is discontinued.

Tetany is usually very satisfactorily controlled by the intravenous administration of 10 cc. of a 10% solution of calcium chloride, or it may be given according to the rule of 0.5 cc. of a 5% solution per kilogram of body weight. It may be necessary to repeat this dose once or twice at ½ hourly intervals. Anhydrous magnesium sulphate given intramuscularly in doses of 1 cc. of a 10% solution per kilogram of body weight, repeated if necessary in 15 to 30 minutes, sometimes is effective. Since this preparation tends to inhibit an already embarrassed respiratory mechanism, it should be used cautiously.

VETERINARY ASPECTS OF UNDULANT FEVER*

By J. F. DE VINE, D. V. S., Goshen, N. Y.
From the J F. De Vine Laboratories, Goshen, N. Y.

UNDULANT fever, Malta fever, Mediterranean fever and Brucelliasis are synonyms for an ailment that has long been recognized as affecting man, and more recently lower animals.

Perhaps nowhere in the annals of veterinary medicine, do we meet with an inter-communicable infection with more vagaries than surround that occasioned by the Brucella group of organisms. The whole subject as to its transmissibility to man is clouded with a good bit of uncertainty. There seems to be missing a link, that if found, might explain the present *paradoxes and simplify prevention.*

Epochs in the History of Brucelliasis

The history of Brucelliasis has been rather unusual. Perhaps its great epochs might be divided as follows:

1. Bruce's discovery of the micrococcus melitensis in 1887.

2. Bang's isolation of the Brucella abortus in 1897.

3. Craig's report, in 1905, of the first case of Malta fever in the United States.

4. Traum's isolation, in 1914, of the Brucella abortus from the liver, kidney and stomach of a porcine fetus.

5. Evans' observation, in 1918, that there was a close relationship between the organisms of Malta fever and that of infectious abortion in cattle.

6. The report by Bevan, to the Southern Rhodesia Veterinary Association in 1921, of a case of undulant fever in man due to the Br. abortus of bovine origin.

7. Keifer's report, in 1924, of the first case of human infection of Brucella abortus in America, the clinical picture being that of Malta fever.

8. Carpenter and Merriam, in 1926, isolating the Brucella abortus from the blood of undulant fever patients and causing abortion in heifers with this organism.

In 1887, David Bruce, a Surgeon Major of the British Army, isolated the organism of Malta fever from the organs of a fatal case. He called this organism micrococcus melitensis but it is now generally known as Brucella melitensis.

In 1897, Prof. Bang, a veterinarian of Denmark, isolated a short rod-shaped organism which conformed to Koch's postulates and is now recognized as the principal causative factor of abortions in cattle. Later it was found that contagious abortion due to organisms of the Brucella group occurs naturally in goats, cattle, sheep (Dubois), swine (Hayes and Traum, Hadley and Beach, etc.) horses (Dubois, Koon and Kelser), mules (Sergent) dogs (Kennedy, Vallet, Van Saceghem, Dargein and Plazy, etc.) cats, rabbits and guinea pigs (Aubert, Cantaloube and Thibault, Shaw) rats and mice; even fowls and ducks can be carriers (Fiorentini, Dubois). It might be well to note here that abortion in mares is usually due to quite a different organism, the B. abortivo-equinus, which belongs to the salmonella group. As for mules, they conceive so seldom that abortion cannot be frequent or of much moment.

Biological Characteristics of the Organisms of the Brucella Group

The organisms of the different species of lower animals are not, in a true sense, pathogenically inter-changeable. For instance, Cotton and Buck, of the United States Bureau of Animal Industry Experiment Station, proved that the Br. abortus of the bovine variety has a low pathogenicity for swine and that while the swine strain is more virulent for guinea pigs than the bovine, it fails to infect cattle by the natural route, though cattle may be infected with this strain by intravenous injection. It has been found that the swine germ may persist in guinea pigs for two years or more, whereas the bovine strain usually disappears within a year.

McAlpine and Slanetz report there are other differences of the organisms of the Brucella group that may be determined by the use of biochemical methods. Their laboratory technique will probably be discussed by our able colleague, Dr. Gilbert. In view of their findings, they suggest that most of the human infections with Br. abortus in the United States are caused, not by abortus of bovine origin, but by abortus of porcine origin and, since porcine strains of abortus are known to be much more pathogenic for experimental animals than the bovine types, they think it

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 3, 1931.

abdomen becomes considerably distended. There is present intense toxemia and marked dehydration. The patient appears acutely ill, his cheeks are sunken, his extremities are cold and clammy and his temperature is normal or subnormal, though he insists that he feels fine.

The diagnosis of this condition depends upon first the consideration of its presence as an etiological factor, and, in the last analysis, upon the characteristic blood chemistry findings, which show a rise in the nonprotein nitrogen (25-35 mgm. per 100 cc. of blood), a fall in the blood chlorides (0.45 to 0.50%), and an increase in the CO_2 combining power of the blood (50-70 volumes per cent). In alkalosis the alkali reserve is definitely increased above the normal, and the CO_2 combining power varies between 70 and 100 volumes per cent.

The general principles of treatment of alkalosis are based upon supplying adequate fluids, chlorides and dextrose or other readily oxidizable carbohydrate, and the promotion of renal excretion, elimination through the intestines, and relief of gastric dilatation and duodenal reflux, the latter two of which are discussed in detail under "acute gastric dilatation."

We believe that the requirements for the control of alkalosis, dehydration, starvation and suppression of urine are adequately met by the intravenous administration of 1,000 cc. of 10% dextrose in normal saline twice and 1,000 cc. of 2% saline in 24 hours, given eight hours apart. A similar amount of 5% dextrose in normal saline may be given, though with much more discomfort, by hypodermoclyses in case the intravenous administration seems inadvisable. In addition, one may give retention enemas of 6 oz. of saline or tap water every four hours, or a 10% solution of dextrose in normal saline or tap water as a continuous rectal drip or a 500 cc. Murphy drip of this fluid every eight hours.

The function of the dextrose is that of a diuretic. The advantage of the hypertonic saline is that it supplies a large amount of chloride with a moderate volume of fluids. The principal disadvantage of the hypertonic saline is that it causes thrombosis of the veins. Some of these cases that are receiving large quantities of fluids intravenously show edema of the feet and hands, and it is possible that this is due to the amount of sodium chloride in some instances and not necessarily to the amount of water given.

The acid salts, such as ammonium chloride and acid phosphates, have a tendency to reduce the alkali balance. The acid phosphate is given in doses of 4 cc. every 2 or 3 hours. If vomiting prevents its oral administration, it should be given by rectum, using twice this dose. These salts are so quickly neutralized that they accomplish little toward the relief from the alkalosis.

Insulin may be given with the dextrose solution at the rate of one unit of U-20 insulin for each 1½ gm. of dextrose. Not more than ½ of the carbohydrate given intravenously should be neutralized with insulin. Though the insulin accelerates the rate of metabolism of the sugar and the oxidation of the acetone bodies, it is not necessary except in cases of primary diabetes or hyperglycemia.

Tetany when present is almost pathognomonic of alkalosis. It is of serious import and requires immediate treatment. It results from a diminished available calcium in the blood stream. Snell[8] states that about 50% of the blood calcium is in combination with the serum protein and cannot be removed by diffusion. He states further that there is a diffusible portion, which probably protects the organism against tetany, and that it is upon the diffusible or available calcium that the parathyroid hormone exerts its effect. The parathyroid hormone is believed to be a calcium mobilizer. In case of deficiency of calcium, more calcium is drawn from the skeleton by its action.

Collip[9] has prepared an extract from the parathyroid glands of animals, which has proved very effectual in not only controlling the symptoms of tetany but in causing an elevation of calcium in the blood serum in normal animals. This parathyroid extract has been used clinically with good results in cases of tetany. It is given in doses of 20 to 30 units (1-1½ cc.) and, if necessary, is repeated 2 or 3 times in the first 24 hours. The doses are then diminished according to the condition of the patient. Hypercalcemia may be fatal unless the parathyroid hormone is discontinued.

Tetany is usually very satisfactorily controlled by the intravenous administration of 10 cc. of a 10% solution of calcium chloride, or it may be given according to the rule of 0.5 cc. of a 5% solution per kilogram of body weight. It may be necessary to repeat this dose once or twice at ½ hourly intervals. Anhydrous magnesium sulphate given intramuscularly in doses of 1 cc. of a 10% solution per kilogram of body weight, repeated if necessary in 15 to 30 minutes, sometimes is effective. Since this preparation tends to inhibit an already embarrassed respiratory mechanism, it should be used cautiously.

VETERINARY ASPECTS OF UNDULANT FEVER*

By J. F. DE VINE, D. V. S., Goshen, N. Y.
From the J. F. De Vine Laboratories, Goshen, N. Y.

UNDULANT fever, Malta fever, Mediterranean fever and Brucelliasis are synonyms for an ailment that has long been recognized as affecting man, and more recently lower animals.

Perhaps nowhere in the annals of veterinary medicine, do we meet with an inter-communicable infection with more vagaries than surround that occasioned by the Brucella group of organisms. The whole subject as to its transmissibility to man is clouded with a good bit of uncertainty. There seems to be missing a link, that if found, might explain the present paradoxes and simplify prevention.

Epochs in the History of Brucelliasis

The history of Brucelliasis has been rather unusual. Perhaps its great epochs might be divided as follows:

1. Bruce's discovery of the micrococcus melitensis in 1887.

2. Bang's isolation of the Brucella abortus in 1897.

3. Craig's report, in 1905, of the first case of Malta fever in the United States.

4. Traum's isolation, in 1914, of the Brucella abortus from the liver, kidney and stomach of a porcine fetus.

5. Evans' observation, in 1918, that there was a close relationship between the organisms of Malta fever and that of infectious abortion in cattle.

6. The report by Bevan, to the Southern Rhodesia Veterinary Association in 1921, of a case of undulant fever in man due to the Br. abortus of bovine origin.

7. Keifer's report, in 1924, of the first case of human infection of Brucella abortus in America, the clinical picture being that of Malta fever.

8. Carpenter and Merriam, in 1926, isolating the Brucella abortus from the blood of undulant fever patients and causing abortion in heifers with this organism.

In 1887, David Bruce, a Surgeon Major of the British Army, isolated the organism of Malta fever from the organs of a fatal case. He called this organism micrococcus melitensis but it is now generally known as Brucella melitensis.

In 1897, Prof. Bang, a veterinarian of Denmark, isolated a short rod-shaped organism which conformed to Koch's postulates and is now recognized as the principal causative factor of abortions in cattle. Later it was found that contagious abortion due to organisms of the Brucella group occurs naturally in goats, cattle, sheep (Dubois), swine (Hayes and Traum, Hadley and Beach, etc.) horses (Dubois, Koon and Kelser), mules (Sergent) dogs (Kennedy, Vallet, Van Saceghem, Dargein and Plazy, etc.) cats, rabbits and guinea pigs (Aubert, Cantaloube and Thibault, Shaw) rats and mice; even fowls and ducks can be carriers (Fiorentini, Dubois). It might be well to note here that abortion in mares is usually due to quite a different organism, the B. abortivo-equinus, which belongs to the salmonella group. As for mules, they conceive so seldom that abortion cannot be frequent or of much moment.

Biological Characteristics of the Organisms of the Brucella Group

The organisms of the different species of lower animals are not, in a true sense, pathogenically inter-changeable. For instance, Cotton and Buck, of the United States Bureau of Animal Industry Experiment Station, proved that the Br. abortus of the bovine variety has a low pathogenicity for swine and that while the swine strain is more virulent for guinea pigs than the bovine, it fails to infect cattle by the natural route, though cattle may be infected with this strain by intravenous injection. It has been found that the swine germ may persist in guinea pigs for two years or more, whereas the bovine strain usually disappears within a year.

McAlpine and Slanetz report there are other differences of the organisms of the Brucella group that may be determined by the use of biochemical methods. Their laboratory technique will probably be discussed by our able colleague, Dr. Gilbert. In view of their findings, they suggest that most of the human infections with Br. abortus in the United States are caused, not by abortus of bovine origin, but by abortus of porcine origin and, since porcine strains of abortus are known to be much more pathogenic for experimental animals than the bovine types, they think it

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 3, 1931.

reasonable to suppose that cows may become infected by porcine strains if kept in close proximity to swine. Theobald Smith holds very similar views.

Hardy's investigations of the clinical aspect of human cases of undulant fever in Iowa show that those yielding porcine strains suffered more severely than those yielding bovine strains.

A study of the organisms of the Brucella group reveals, at once, that they are rather unusual as to their ways of invasion, places of living and their biological behavior. For instance, the Br. abortus may invade the blood stream through the alimentary tract, through the skin, or through the conjunctiva and, while we are prone to think of abortion as a venereal disease, still no one has yet succeeded in infecting a bovine through the vaginal canal.

Here we have an organism that in certain species of animals, such as the female of the bovine may be manifest by cotyledonitis and placentitis, not infrequently causing death and expulsion of the fetus. The same organism may live and apparently thrive in the male animal of another species, without causing the least semblance of malignancy. It has been recovered from abscesses, such as fistulous withers in the horse. There may even be a striking difference in its behavior in the male and the female of the same species. For instance, it stands accused of causing an undulating fever in man and according to Larson and Sedgwick (1913) the serum of a number of women who had aborted gave a larger percentage of positive reactions when Br. abortus was used as antigen, than when the usual Wassermann test was applied, but the authors do not indicate that the clinical picture simulated, in any way, Malta fever.

Another unusual biological characteristic of the Brucella group is its low infectivity for young animals. According to Hasseltine, children have a very considerable immunity in the case of Malta fever, and we know this to be true in the case of young bovines. Calves born of diseased mothers may be allowed to live with their mother and drink her milk, or milk from the infected udders of other cows, for months, but if removed from such exposure, for a few weeks, the infection dies out and, if such animals are not exposed again, after they reach sexual maturity, most of them continue to give a negative reaction to the agglutination test: so, apparently the bovine strain of this group requires sexual maturity (a developed udder) for a suitable habitat and a pregnant uterus to become pathogenic for the host.

Our laboratories recently ran agglutination tests on a kennel of wolf hounds, fed on milk from cows that reacted to the abortion test. While some of these were mature dogs, most of them were puppies. All reacted to high dilutions yet suffered no inconvenience. Evidently sexual maturity is not essential in this species to become a carrier of Br. abortus.

Since beginning this paper, agglutination tests with Br. abortus antigen have been run on three of my laboratory associates with the following results:

No. 1—Working in the pharmaceutical department and not handling biologics or animals, an occasional milk drinker—in dilution 1-50, there was a weak and slow reaction.

No. 2—Laboratory Director, handles many blood samples and is around cattle, more or less, not a milk drinker—gave a weak and slow reaction in dilution 1-50.

No. 3—Laboratory assistant, milk drinker—in dilution 1-875 gave a rapid and complete reaction.

The blood reacting to the highest dilution (No. 3) was that of a young man, 23 years of age, a large, strong, athletic fellow, and apparently in perfect health, but the only one of the three being a heavy milk drinker.

At the same time, we also tested a neighbor, a baker, not in contact with farm animals or the laboratory and does not drink milk in any form. His blood gave a negative reaction to all dilutions—as low as 1-50.

This simply corroborates information that others have published.

Nicolle, Burnet and Conseil attempted to decide the question of the pathogenicity of Br. abortus for man by experiments on human volunteers. Five subjects were given massive doses (800 to 900 millions) of the organism subcutaneously and failed to develop any signs of infection, even agglutinins being absent from the blood.

The information they present would appear prima facia, to knock the whole theory of thansmission by simple contact or milk drinking into a cocked hat.

Pathological Characteristics of the Organisms of the Brucella Group

If we compare the pathological characteristics occasioned by the Br. abortus in the bovine and the Br. suis in swine with the clinical picture occasioned by the Br. melitensis in man, it would appear that there is no pathogenic relation whatever, but we shall need to admit that we have an analogous picture in the goat. The only manifestations of disease that Br. melitensis causes in the goat are the same as those occasioned by the Br. abortus in the cow and the suis in the sow, that is, abortion and its corollaries. The goat may not abort but act simply as a carrier, re-

maining apparently well and still infect man. This is exactly what the bovine and the porcine now stand accused of. There is one striking difference, however, and that is the regularity with which the micrococcus melitensis in goats' milk conveys the disease to man. You will recall that in 1905 sixty-five goats, all apparently healthy, were shipped from the Island of Malta to America. During the passage the goats' milk was drunk by the Captain and most of the crew with the result that nearly all those who drank the milk developed Malta fever. In contrast to this, thousands—yes, perhaps millions—are daily drinking milk carrying Br. abortus and the incidence of infection, according to reports, apparently is very low.

Investigators at the Cornell Veterinary College have found that about 20 per cent of the raw milk examined in that territory was infected with Br. abortus, as determined by the guinea pig test, and in one positive reacting herd 75 per cent of the animals were proved to excrete Br. abortus from one or more quarters. These data are in keeping with reports of many, many other investigators. For instance Schroeder and Cotton of the United States Experiment Station found milk infection in 83½ per cent of cows examined.

Some of the Characteristics of Br. Abortus Bovine

1. In the female bovine, the organism seems to have a particular predilection for placental tissue. In fact, it requires a pregnant uterus to become pathogenic, since the utero-chorionic space is the only place in the female bovine where the organism is known to produce pathological changes.

2. If exposure occurs when the animal is not pregnant, instead of becoming actively pathogenic, the organisms may locate in the udder or the lymphatics near the udder and cause no apparent systemic disturbance and still the animal's blood for years may give a high titre. This may also be true in the case of an animal that is pregnant. Or to make this statement more explicit, not all reacting bovines abort, even though their blood gives a high titre. Abortions in some infected herds may approximate 100 per cent, but in the case of mature animals, it is not an uncommon thing to have a considerable number of the herd react to a high titre and the actual abortions not exceed the percentage that may occur in a non-reacting herd—say around 5 per cent.

We have at our laboratories a mature cow that aborted an 8-months dead fetus, five years ago. Following abortion she was given the best possible care with our present knowledge. She has since conceived promptly and regularly and dropped four normal calves, but her blood and milk serum continue to give positive reaction to a fairly high dilution.

There was a cow at the United States Bureau of Animal Industry Experiment Station that Schroeder and Cotton proved, by guinea pig inoculation, carried infection in her udder for a period of over 7 years.

3. If on exposure a bovine animal becomes actively infected and aborts early in pregnancy, that is, while the cotyledons are still small and the circulatory system still primitive, the membranes slip away with the fetus and, so far as we can determine, the act of abortion, at this period, occasions little or no constitutional disturbance of the host. In fact, we have observed that when abortions occur early, most mares and cows show all the characteristics of estrum and that both of these animals will readily take service from the male, the same day they abort, or before the act of abortion is completed. I have also observed instances where conception took place on such occasions. This would indicate in the case of early abortions, that infection of the uterus must be of a low type, if conception and implantation can take place so promptly.

4. If a bovine animal does not abort early in pregnancy, that is not until after the 4th or 5th month, it is quite usual for such an infected animal to carry the fetus 7 or 8 months, or even the full term, the Br. abortus producing a low type of inflammatory irritation leading to necrosis of the chorionic villi and the maternal cotyledons. Cotyledonitis and placentitis are usually so severe as to cause retention of the fetal membranes with a resultant cervicitis, endometritis and, not infrequently, more chronic impediments such as pyometra, salpingitis, cystic ovaries or cystic degenerated corpora lutea. When the fetal membranes are retained, it has been the custom, as long as within the memory of those living, to attempt their removal by hand, the manipulation being spoken of as "unbuttoning." Since the villi of the chorion dip into the tufts of the maternal cotyledons, the membranes may be pulled apart or unbuttoned, if the inflammatory exudate has not become too solid. This procedure has been in vogue all these years and no special precaution has been taken by operators to protect themselves from infection and, so far as we can learn, infection has been exceedingly rare, this not withstanding that the fetal membranes and the uterus have been literally teeming with Br. abortus organisms. We now know the latter to be true and that the uterus continues to be infected for several days or weeks after an animal aborts, or goes full term and retains her placenta. In fact, the Br. abortus has been

recovered from the uterus as late as the 63rd day after abortion. This being so, it would seem as if there were some information wanting as to the present susceptibility of human beings, judged by the number of cases that are now reported as infected by contact with living or dead animals. My associates and I, in our practice, during the past 30 years, have manipulated or removed hundreds and hundreds of diseased placentæ and, so far as we know, we have suffered in no way from the procedure, and yet we have unintentionally done the very thing we would advise against, that is, it has been necessary to strip to the waist in all sorts of weather and sometimes in rather filthy surroundings. The usual procedure is to clean the external genitals as best can be and the hands and arms are lathered with warm water and soap. The arm is drawn in and out so frequently that the epidermis is often actually rubbed off. It is then customary to wash up in clean water and pass to our daily routine. So, I repeat, if thousands of veterinarians have gone on doing this thing, for years and years, it would seem strange that simply being in contact with live farm animals, or handling carcasses at abattoirs would be so conducive to infection. Such contradictory evidence surely suggests that there are other factors involved.

In view of information of this character and inevitable daily exposure of those who drink raw milk, the natural reaction is—if man is susceptible to Br. abortus and Br. suis, why are there not more cases of human infection?

Dr. Hasseltine sums up the situation rather logically. In his "Current Studies of Undulant Fever" he states, "I can't answer this question directly. However, if you can tell us why the milk-borne epidemic of typhoid fever in Montreal caused only about 1 person out of every 160 in Montreal to take typhoid, and why all of us who drank typhoid-infected water in the days before filtration and chlorination did not take typhoid fever, I will say that you will probably find that your answer will apply to the above question on undulant fever. We know that the Br. abortus is not present in large numbers in milk—50,000 per cubic centimeter being an exceptionally high number. We know that under laboratory conditions it takes Br. abortus a week to achieve any such multiplication as B. typhosus does in less than one day.

"We also know that the bovine strain of Br. abortus is less pathogenic for animals than the goat or swine strain. We believe that resistance to disease is a variable factor among persons, and differs in any particular individual at different times. We know from experience that seed and soil are not always the only factors necessary to insure reproduction. When we find the accessory factors that determine the incidence of infectious disease and learn how to control these factors so that the proper combinations for the production of disease will not occur, our communicable disease problem will be much simplified, if not completely solved."

While it is true that all this evidence is more or less controversial and in no way satisfying to the trained or untrained mind, still it is highly probable that it will aid research workers in eliminating the irrelevant and patching together the important and we must admit that out of it all there has come epidemiologic data as to Br. abortus bovine and Br. abortus suis causing a serious illness in man that is in no way distinguishable from melitensis. For reasonable proof we need only refer to such evidence as has been published by Evans, Carpenter, Burnet, Huddleson and Hasseltine.

Affirmative Evidence

Information on the transmission of Br. abortus bovine and Br. abortus suis to man bears origin with the acute observations made by Alice Evans in 1918. Since then a wealth of literature has sprung up in most every civilized country in the world. Of all that has been published, perhaps none is more conclusive or convincing than that given us by Carpenter and Merriam. In the summary of their report on "Undulant Fever from Brucella Abortus" (1926) they state "From two patients with undulant fever, two strains of micro-organisms indistinguishable from Brucella abortus have been isolated. The organism was isolated seven times from the blood and twice from the urine in Case 1, while it was recovered only twice from the blood and not from the urine in Case 2. There was a marked difference in the severity of the disease in these cases. The course in Case 1 was extended over a period of twelve weeks. The patient was confined to his bed practically all this time. There was extreme emaciation and anemia with marked debility. The temperature was of the remittent type and fluctuated between nearly normal in the morning to 103 and 105 in the evening. This high temperature was followed by a chill and profuse sweating, after which the temperature returned gradually to normal.

"Case 2 was comparatively mild. The patient was not confined to his bed during the course of the disease, but he rested often in the afternoon because he felt weak, tired and unable to work during the whole day. The type of fever was identical with that in Case 1, but the temperature was never higher than 101.5. There was practically no change in the blood picture. All of the other symptoms

were essentially the same as those observed in Case 1, except that all were much less serious. Biologically, the two cultures isolated from these cases behaved like Brucella abortus (Bang). By the agglutinin absorption test, they showed that they were of the abortus variety rather than melitensis. We produced abortion in two heifers in their first pregnancies by injecting some of the culture intravenously. A placentitis typical of Brucella abortus infection in cattle was caused, and the cultures were recovered from the placentas and various organs of the fetuses. The cultures were virulent for guinea-pigs and produced lesions, which in their gross appearance, were typical of those produced by cultures of Brucella abortus that have been isolated from cattle."

In another report Carpenter states, "Abortion was produced in five pregnant heifers by the intravenous injection respectively of five strains of human source. The organism was recovered from the colostral milk, placenta and fetus. The infection established itself in the udder and was present in the milk of one case for 6½ months after the animal aborted. The cultures isolated from man were more toxic for the pregnant heifers than the bovine types and produced abortion in a shorter time than have bovine strains as reported by other observers."

Prevention

All of this naturally leads to the question of prevention. Two methods suggest themselves rather clearly.

One is eradication of contagious abortion in cattle and swine.

The other is pasteurization.

While many progressive livestock owners are attempting to rid their herds and flocks of this scourge it will, of necessity, require a long, tedious pull.

As to pasteurization: again quoting Hasseltine, "In cities having only a portion of their milk pasteurized, undulant fever has picked out the user of raw milk with as much precision as smallpox picks out the unvaccinated.

"In the January issue of the *Health Messenger* of the Illinois State Board of Health, it was reported that Arnold had found that 140°F. for 40 minutes was required to kill certain strains of Br. abortus. He did not give details, and it will be noted that the temperature he employed is 2 to 3 degrees below standard pasteurization temperature. On the other side numerous investigators have reported pasteurization temperature and exposure effective in killing the various strains of Brucella."

In the face of all this affirmative data, it would seem that until we have more definite knowledge on the whole subject, those who advocate where practicable the pasteurization of all milk not coming from abortion-free herds are giving good advice and supporting rightful public health policies.

I have purposely avoided burdening you with wearisome statistics, but have appended a list of references for any who may be sufficiently interested to review such data.

PSYCHIATRY IN RELATION TO LITERATURE*

By LOUIS J. BRAGMAN, M.D., SYRACUSE, N. Y.

PERHAPS an apology should be necessary in presenting such an unclinical subject as the relation of psychiatry to literature before a practical medical organization. Yet there are certain approaches to this topic that are of proper and pragmatic interest to the psychiatrist. For there are undisputed lessons to be learned from the psychopathological aspects of life and

*Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 2, 1931.

letters that are of immense importance for a complete realization of the problems that face the prosaic patient. Psychiatry has contributed enormously to an understanding of creative expression, and particularly to literature; similarly, literature has bestowed considerable of value on the art and science of psychiatry.

There is no other department of medicine that ramifies to the extent that psychiatry does into all fields of human thought and activity. In addition to the usual physical, chemical, and biological sciences it utilizes material from sociology, psychology, religion, anthropology, genetics, among others, and even makes use of mysticism and metaphysics. Especially does it affiliate itself with the sublimating achievements of the human race—with music, painting, sculpture, and all forms of literary and artistic expression. In fact, it is the outstanding strength and weakness of the psychiatrist that he sits with the gods on Mount Olympus, and attempts to survey and comprehend, in his own peculiar fashion, all the mechanisms of what Voltaire called this best of possible worlds.

Should one grant this viewpoint to be correct, it will be found that the psychiatrist looks at the manifestations of the human comedy and tragedy at large to be merely nothing more than specific types of understandable human behavior, on a grand or minute scale. From one extreme to another, from world wars to marital discords, from epic poems and paintings to schizophrenic dabblings, from world re-creating inventions and discoveries to perpetual motion devices, life is seen as a matter of degree and of relativity.

This is particularly true in the realm of letters. What lessons in psychopathology can be gleaned from a study of literature? The average patient who offers himself to the psychiatrist shows on the surface very little of psychodynamic interest; and often what lies beneath is diluted in nature, difficult of access, and quite presumptive to the understanding. But a close study of the unconsciously motivated productions of the makers of literature very often gives a magnified perspective of the manner in which the mind in distress attempts to solve its conflicts. As Nelson Antrim Crawford says, speaking of *Literature and the Psychopathic,* in the *Psychoanalytic Review* for October, 1923: "To the student of abnormal psychology the legend, popular literature, and literature revelatory of actual life, are all significant. In the legend he finds race taboos, in the popular literature of the day he discovers this re-inforced by the mass of contemporary racial taboos, in literature that aims to be realistically revelatory of life he finds material for study such as he can hardly obtain from any group of patients." In the lives of those souls who, as Jeannette Marks says in her book *Genius and Disaster,* are crushed by a cruel social mechanism and are accordingly more often God than realized, can be discerned, on the basis of their writings, their inner discords and their concomitant strivings for harmony. For just as a master of words, a *menschenkenner* such as Dostoievsky can give a more vivid, a more realistic picture of epilepsy or idiocy than the clinically astute but ingloriously mute physician, so can a gifted, inspired poet or painter, for instance, depict in more glowing words or colors than the narrow, halting patient, the definitely painful situation from which he is suffering or of which he is becoming aware.

In writing what was to be his favorite poem, *The Chambered Nautilus,* Oliver Wendell Holmes said that he was filled with "the highest state of mental exaltation and the most crystalline clairvoyance" that had ever been granted him. For, he declared, the poet's special gift was that "lucid vision of one's thought and all forms of expression which will be at once precise and musical."

Is the cognizance of this mental exaltation, this crystalline clairvoyance, this lucid vision of significance to the psychiatrist? Can he interpret this creative inspiration as a form of dynamic action which has its source in the unconscious mind of the creator? In other words, is there a continuity, a universality, in that all forms of writing are allied by representing a need for self-expression on the part of the author? And would it not seem that the greatest step in psychiatry consisted in breaking away from the Kraeplinian method of classifying the patient, and instead, listening and observing to comprehend the vital urge back of the symptoms? If this is true, it is true reciprocally for literature and psychiatry, for writer and patient.

And it is undoubtedly true, that "a chaotic self-state," as one writer puts it, "drives the artist to strike at the world's wrongs; that great writing springs from a terrible driving unrest." And it would seem true, despite the judgment of Louis Untermeyer, the poet and critic, who declares:

"Certain types of great art *may* spring from fever, maladjustment, hypersensitivity, discontent; but even more of the world's masterpieces —in words and wordless—have risen from nothing more 'heretical' than peace, acceptance, affirmation."

For is not this peace, acceptance, and affirmation merely the negative, the passive phase, the submissive factor, representing no less turmoil and discontent for having been suppressed and submerged? Did not Shakespeare "mirror the tragedy of his own being, reflecting lust, hate and jealousy?" Did not mental warfare produce Beethoven, spiritual conflict the visions of Blake, inner troubles DeQuincey, Baudelaire, Coleridge, Rossetti, Swinburne, and the Thompsons? Cannot an ample psychiatric case be made out for

each of the great and enduring names in American literature: for Poe, Emerson, Thoreau, Hawthorne, Melville, Whitman, Mark Twain, and Henry James?

For all this, psychiatry answers that genius and psychosis are inter-related, that the works of men grow out of their mental torments which made their lives miserable but produced masterpieces of strange and weird and lasting beauty. And what are these masterpieces if not clinical outpourings? E. Graham Howe, writing on *Motives and Mechanisms of the Mind* in the *Lancet* for Feb. 14, 1931, says: "It is probable that much that has been written and much that has been said would never have seen the light of day had there not been emotional repression behind it." In an article in the Proceedings of the Royal Society of Medicine for May, 1930, called *Psychiatry in Relation to Biography and History,* Hubert Norman offers further proof that "much of the best, or at any rate, the most impressive work in the world is the product of individuals in a state of unstable nervous equilibrium." And C. Macfie Campbell, in a study of *Psychology and Biography,* in the *American Journal of Psychiatry* for March, 1931, shows that there is much of psychopathological value to be obtained from an investigation of biographies and autobiographies as case histories. For, he says, biography demonstrates "that outside the clinical field there are a great many experiences which form part and parcel of the varied texture of human life and which are not monopolized by the patients of the psychiatrist." *Genius and Disaster,* by Marks, *The Man of Genius,* by Lombroso, *The Insanity of Genius,* by Nisbet, and *The Great Abnormals,* by Hyslop, afford numerous and detailed instances of this relationship between conflict and creative sublimation.

In addition to a study of the works of frustrated genius, the psychiatrist can well profit by an analysis of those novels that are reputably not entirely sane. One need not always presume that the author has outstanding conflicts, in these instances, for it is conceivable that some writers can objectify, can penetrate into the souls and lives of their characters, and thus give clinical verisimilitude to their creations. It is one of the incidental outcroppings of the widespread knowledge of the doctrines of Freud that artists in all spheres have striven to re-create and re-animate the mechanisms he has promulgated. The works of D. H. Lawrence who more than any one man except Dostoievsky, wrote his pathological condition down in his books, Waldo Frank, and Marcel Proust are some outstanding examples. De Maupassant's *H'ourla,* James' *Turning of the Screw,* Stetson's *The Yellow Wall Paper,* which treats of hallucinosis associated with exhaustion, Beraud's *Lazare,* a study of double personality, Dominique's adventures of a madman called *Notre Dame de la Sagesse,* and more recently the works of Julian Green—notably *The Closed Garden,* and *The Dark Journey,* offer a tremendous wealth of clinical material to stimulate the diagnostic and descriptive acumen of the psychiatrist. George Duhamel's *Midnight Confession* is a study of dementia precox; general paresis is the central theme in Paul Morand's *La Nuit de Portofino Kulm;* and *The Paranoic* is depicted in a story by that name by Dr. George L. Walton. Huysmans and Proust among others, knew 'degeneracy' in the quick, and their descriptions of it are recognized psychopathologically as true to life. As stated by Groves and Blanchard in their *Introduction to Mental Hygiene,* in the chapter on *Mental Hygiene Aspects of Literature*: "There are many contemporary novels which so closely parallel actual experience that they can be recommended to the student who would learn to understand human conduct. They are as true to the principles of psychology and psychopathology as are the case records of a clinic."

From another angle the relation between psychiatry and literature can be surveyed in an investigation of what might be called personal human documents. The bibliography of studies in self-revelation and self-revaluation by the mentally afflicted has in recent years been rapidly mounting. The best known, of course, is *The Mind That Found Itself,* by Clifford Beers. But a large number of others can be cited, the readings of which are well worth while to the psychiatrist. In James Hendrie Lloyd's *The Case of William Cowper,* is found a reference to the memoirs of this poet who had recurrent melancholia and suicidal impulses, and who, in 1816, described his own mental state. E. G. O'Donoghue, in his *Story of Bethlehem Hospital,* refers to the remarks of Cromwell's porter, who described his own madness. In 1871 the impressions from the inside of a hospital for the psychotic from the standpoint of a patient were given in an anonymous book called *Behind the Bars.* Arthur Symons wrote *Confessions—A Study in Pathology,* in which "this critic and translator charts his own reeling back and forth across the slender line that separates the sober health of the mind that we call reason, and headlong insanity."

Gerald de Nerval, the romantic poet, in his *Le Reve et la Vie,* presents his psychosis as a marvellous adventure into psychic realms. In the *Diary of an Unsuccessful Man,* Barbellion gives the steps in the downfall of his mentality. Norman Douglas, author of *South Wind* and *Goodbye to Western Culture,* presents in *Nerinda,* in 1901, a study of what he calls his progressive insanity. In a footnote to *Nerinda,* Douglas refers to the *Inferno* of Strindberg as "a convincing study of the borderland between reason and unreason, of the paranoic temperament as revealed from within," and adds that it should serve as a

textbook for medical men. *The Shutter of Snow,* by Emily Holmes Coleman, contains a description of the psychotic experiences of a former state hospital patient. *Reluctantly Told,* by Jane Hillyer, is the autobiographical sketch of the sensations, ideas, and reactions of a woman going through a psychotic attack. "Here," writes a reviewer, "one can follow the tension, the dissociation, the tenuous hanging on to some semblance of ego function, and a final compulsive defense mechanism which would wall up the spiritual abscesses and prevent self-destruction." This work, a paragon of literary and dramatic style, is compared with *Selbstschilderung der Verwirtheit,* by an assistant in the psychiatric clinic at Heidelberg, which contains much of the same kind of material in quite a different form. *A Challenge to Neurasthenia Through a Patient's Eyes* is a recent book by Doris Mary Armitage. A self-study in perversions is given in *The Invert,* by one who calls himself *Anomaly. The Recovery of Myself,* by Marian King, with a preface by Adolph Meyer, relates a patient's experiences in a hospital for mental disease, following her adventure with veronal. Giovanni Papini, according to the chapter on *Lunatics in Literature* in Joseph Collins' *Taking the Literary Pulse,* was admittedly autobiographic, in *Un Uomo Finito,* a revelation of morbid childhood, raging adolescence, furious flights from reality, near-delusions of grandeur, aspirations towards omnipotence, and descent to depths of depression. A. C. Benson, in *Thy Rod and Thy Staff,* gives a detailed account of a long depressive experience.

The *tour de force* of personal documents, of interest to psychiatrists, is *The Locomotive God,* by William Ellery Leonard. Studied together with his lengthy sonnet-sequence, *Two Lives,* and his book of verse, *A Son of Earth,* a masterful self-presentation of the case of a *phobiac* reveals itself, unparalleled perhaps save by Rousseau's *Confessions* in the literary history of soul-baring. Two comprehensive analyses of the case of Leonard have appeared in psychological journals. Thus the psychiatrist can aptly paraphrase an old saying, and express the wish that his patient write a book, for thereby hangs understanding for the physician, and comfort in catharsis for the afflicted. In juxtaposition with these free and impassioned outpourings, scientific textbooks and clinical reports of detailed cases are barren and dull.

Another aspect of the relation between psychiatry and literature is found in connection with the so-called new school of literature comparable to what has been termed *futurism* in art. Here one encounters the stream of mental activity and the content of thought of such obtuse and obscure writers as James Joyce with his *Ulysses* and *Work in Progress;* Gertrude Stein with her *Tender Buttons;* T. S. Eliot with his *Waste Land,* and others, who follow closely the stereotypies, the mannerisms, the repressions, the archaic ways of thinking, and the symbolizations of the schizophrenic. Considering only the symbolism, one finds that it has exercised quite a generating force in modern literature. Edmund Wilson, in a recently published study in symbolism called *Axel's Castle,* finds that in relation to literature symbolism represents an effort to communicate by means of a unique personal language ideas, feelings, and sensations more faithfully than they are rendered through the conventional and universal language of ordinary literature. Mallarmè, the great symbolistic French poet, had an imagery so personal that few people in his day could understand his work any more than Joyce and Proust today can be comprehended. Modern symbolists are even using multiple associations, which are supposed to include and fuse characters, places, motifs, and patterns of behavior. Is not this condensation, this unique personal language, this departure from ordinary modes of expression the business of the psychiatrist to unravel and ferret out, as to the wish that lies back of the disguise? Is it not true equally of the psychoses and of symbolic literature that each deals with the cultivation of private phantasies in the face of contemporary reality, that thus the writers if not manifesting, at least are escaping from a neurosis by the exercise of a primitive or childlike attitude? As one reviewer says of the modern Imagists, they are "a band of adolescent escapists in one way or another cut off from the direct realities of their time." Can the meaning of this type of literature otherwise be understood?

It may be inferred from these relations of psychiatry to literature that to the alienist nothing should be alien. It can further be surmised that a great share of literary criticism must perforce be psychobiological, for the human element is always to the fore; the feelings, instincts, urges, hopes, and disappointments of the writer play an integral part in his creations. From a non-psychiatrical angle this situation is not as morbid as it may seem—*Khubla Khan* is no less perennially beautiful for having been hasheesh-dream conditioned. John Greenleaf Whittier said: "A physician could not be otherwise than melancholy—he sees incipient disease where the uninitiated see only delicacy." But great writing is no whit less great for the conflicts that gave it birth; and to the psychiatrist an inestimable benefit accrues if he approaches literature in this fashion.

THE IMPORTANCE OF VENTILATION IN OXYGEN TENT AND OXYGEN CHAMBER THERAPY

With a Description of an Improved Oxygen Tent

From the Department of Medicine of the College of Physicians and Surgeons Columbia University and the Presbyterian Hospital, New York City

By ALVAN L. BARACH, M.D., NEW YORK, N. Y.

THE development of modern oxygen therapy in the form of oxygen tents and oxygen chambers necessitated the use of confined atmospheres with artificial systems of ventilation. In the provision of high concentrations of oxygen it has become increasingly evident that atmospheric conditions should be provided which in themselves make for the comfort of the patient.

In the provision of a healthful air environment one of the most important considerations to be borne in mind is the capacity which the surrounding atmosphere possesses of facilitating or retarding the rate at which heat is dissipated from the human body. The heat-loss from the body varies in its mode, depending on the temperature, humidity and velocity of air motion of the surrounding environment. At certain atmospheric conditions characterized by high temperatures, dissipation of heat by radiation, convexion and conduction are zero. At these points cooling is accomplished solely by evaporation of water from the skin. It has been found that certain combinations of temperatures, humidities and air motions may be made which feel alike to the human body and which result in a constant rate at which heat is dissipated. These are called "effective temperatures."[1]

Thus, air at 95°F. with a relative humidity of 10% seems no warmer to one's body than when the air is 75°F. with a relative humidity of 100%. The American Society of Heating and Ventilation Engineers have worked out combinations of temperature and humidity which give the same feeling, although the temperature itself may vary widely, viz.:

Temperature		*Relative Humidity*
95°	with	10%
90°	with	23%
85°	with	43%
80°	with	68%
75°	with	100%

Both the rate of heat production and heat-loss from the body are the same at any given effective temperature, regardless of humidity or air motion. Comfort zones have been established in which normal individuals feel best. At *increased effective temperatures*, which tend to retard the loss of heat from the body, interference in the normal functioning of the various organs takes place with changes in well-being, rate of heart beat, arterial blood pressure, body weight and other physiological criteria. In the table below from Houghten and Yagloglou,[2] the atmospheric conditions along the 70°F. effective temperature line for still air are given.

TABLE 1.—Atmospheric Conditions along the 70°F. Effective Temperature Line for Still Air, from the Data of Houghten and Yagloglou. The Skin Surface Temperature is always 95.2°F.

Relative Humidity %	Dry bulb Temperature °F.	Difference of Skin and Dry bulb °F.	Relative Difference of Fourth Powers of Absolute Temp. %
100	70.0	25.2	100
90	71.2	24.0	95
80	72.5	22.7	90
70	73.9	21.3	84
60	75.3	19.9	78
50	76.9	18.3	72
40	78.7	16.5	66
30	80.8	14.4	59
20	83.0	12.2	52
10	85.6	9.6	41
0	88.4	6.8	28

At an effective temperature of 70° F., where the humidity is very high, most of the heat will be lost by radiation, convexion and conduction. If the humidity is low a larger proportion of the heat will be dissipated by evaporation. The sum of the loss of heat remains the same.

Although the rate of heat loss is always the same at a given effective temperature, the mode of heat loss is altered, depending upon the humidity, temperature and the velocity of air motion. It is obvious that radiation, convexion and conduction will be largely employed in the presence of a high humidity and a low temperature whereas the rate at which water becomes available for evaporation will be increased with a low humidity and a high temperature. These general considerations have emphasized the importance of heat transfer from the human body to the air. The comfort zones established for normal people, however, do not apply to patients suffering from febrile or dyspnœic conditions. In actual practise, the dyspnœic patient with pneumonia or heart disease appears more comfortable at lower effective temperatures than that established for normal individuals. Furthermore, the existence in temperate regions of a wide latitude of temperature variation renders the maintenance of a rigid effective temperature zone undesirable.

Under ordinary conditions during the winter a temperature between 60 and 68 degrees with a relative humidity between 35 and 50% appears

to be the most comfortable zone for patients suffering from shortness of breath, either due to pneumonia or cardiac failure, in our experience. The constitution and the taste of the individual patient must be reckoned with in deciding whether the lower or higher temperature in this range should prevail. During the hot summer weather when the temperature mounts above 90 and the humidity above 60% the patient with dyspœna is especially harmed by the increased difficulty in heat loss. A modification in the atmospheric conditions which would result in a 10-15 degree temperature drop with a lowering of the humidity to between 45 and 50% will in itself cause a feeling of increased well-being even before oxygen has been added to the air. However, a drop in temperature from, let us say, 92°F to 62°F in an oxygen tent would be an unwise procedure. The patient, who may be removed from time to time from the tent, would under these circumstances be exposed to a sudden 30° increase of temperature. This would give him an immediate sense of suffocation until he had compensated in a new way for the increased temperature. Such sharp changes in atmospheric environment would reasonably seem unwise to administer to a patient whose cardio-respiratory mechanism is already impaired. If an oxygen chamber is employed it is more feasible to maintain the patient at a much lower temperature than that of the outside air, provided that the temperature is gradually elevated before the patient is removed.

There is, however, ordinarily no reason for having a temperature and humidity higher in an oxygen tent or oxygen room than that of the hospital or house in which it is placed. As a rule buildings are heated during the winter to maintain a temperature between 68 and 72 degrees; during the summer they take on the temperature of the outside air. When the ventilating system of a tent or a chamber is unable to remove the heat dissipated by the body as fast as it is formed, an increased temperature and an increased humidity develops in the confined atmosphere. This adds to the discomfort of the patient, and may be sufficient to cause profuse sweating and other vasomotor disturbances. Although no pre-determined standards for temperature and humidity for patients suffering from clinical diseases are available, certain general rules may be mentioned. These are intended to apply specifically to cardio-respiratory conditions characterized by dyspnœa in which oxygen therapy is indicated. We therefore exclude ailments such as arthritis in which increased temperature may be thought desirable.

Under ordinary conditions, then, a temperature between 62 and 68 degrees with a relative humidity between 35 and 50% is a comfortable zone. In atmospheres in which high humidity and temperatures are present a ten to fifteen drop in temperature with a corresponding fall in humidity is desirable. The temperature and humidity of the tent should not be above that of the room in which it is placed. When this occurs it indicates a mechanically inefficient mechanism which has the possibility of providing uncomfortable and even dangerous ventillatory conditions. An exception to this rule would have to be made in the case of infants.

The velocity of air motion is usually relied upon to vary the temperature of an enclosed atmosphere. Inasmuch as infants give off much less heat than large adults, both the tent and the chamber should contain a mechanism for varying the amount of cool dry air. In an oxygen tent which contains between eight and twelve cubic feet of air, a velocity of two cubic feet per minute passed through an ice chamber may be adequate for infants, whereas eight to ten cubic feet per minute may be required for a large obese adult. However, because of the great variation in atmospheric conditions a thermometer should be placed within the tent and the flow of air gov erned by its reading. Tests of the humidity should also be made from time to time although it does not seem necessary to have a hygrometer put in the tent at all times. Because of these considerations it seems highly desirable to have a tent in which the flow of air may be arbitrarily varied to conform to the needs of the patient and to control the outside temperature and humidity. A tent that would have a range of two to ten cubic feet of air motion per minute would fulfill most indications.

We suggested the passage of air directly over chunks of ice originally because it appeared to be the most effective way of eliminating heat and moisture.[3]

In premature infants it is sometimes necessary to warm the air within the tent after it has been de-humidified by passing it through the ice. This may be done by hot water bottles but never by the insertion of an electric pad or of any contrivance where a spark may be given off. In the tent which we are to describe at the end of this article provision has been made to insert a series of lamps at the roof of the tent entirely disconnected from the oxygen atmosphere. Since this tent is thermostatically operated any temperature may be achieved in the presence of a relative humidity between 35 and 50%.

The velocity of air motion in oxygen chambers may be varied within wide limits as long as a comfortable effective temperature is maintained. In the chamber at The Presbyterian Hospital, New York, we employed a thermal circulation of the air in which there was a movement of the air from one entire wall to the opposite wall of 25 linear feet per minute.[4] We have recently installed in this chamber a filter to rid the air of dust and bacteria in which the velocity of air movement may be varied between 300 and 1,500 cubic feet per minute. These high velocities are not necessary as far as the provision of a com-

fortable air atmosphere is concerned but have been utilized in connection with the attempt to make the air within the room as dust-free and as bacteria-free as possible.

We wish to mention briefly the use of an air filter which rids the air of 99% of bacteria and dust particles by passing air through it at a moderate velocity. (Protectomotor Company.) In the oxygen tent we have added this filter for cases of dust asthma. In the oxygen chamber it has a similar use. There is, however, another indication for its employment in oxygen chamber therapy where more than one patient is enclosed within the same room. We have found that bacteria accumulate in the air from patients' coughing and forceful talking that are not removed by condensation on brine pipes or by passage of the air through soda lime or ice. The possibility of cross-infection arises because of increase of bacteria in the chamber unless an air filter is employed through which at least one-third to one-half of the cubic contents of the room air be passed each minute. This factor will be additionally discussed in another communication.

There is one other important consideration in oxygen tent and oxygen chamber therapy which remains to be discussed concerning which unfortunately our knowledge is still meagre. The use of enclosed circulated atmospheres necessitates re-breathing of a considerable portion of the atmosphere. A certain leakage of the air environment necessarily takes place through raising the tent fabric or through opening the chamber door. In this way some of the old re-breathed air is replaced by fresh air as well as by oxygen from the tank. Odors are partly dissolved in the cooling process since many of them are water soluble, but some are gotten rid of through leakage and replacement by fresh air. Our knowledge of the rare constituents of the air is so scant as to seriously interfere with any arbitrary standards in this connection. It is of importance to realize, however, that these rare gases may be of value for normal respiration and that they may be partially exhausted by re-breathing. Hershey[5] has conducted recently experiments in which the rare gases argon, neon, krypton, xenon and helium were excluded from chambers in which animals were kept. Without these rare gases, although with a normal amount of nitrogen and oxygen, animals do not survive longer than ten days. Hershey concluded that the rare gases seemed to play a part in normal life equally as important as oxygen. Fidler[6] has suggested because the rare gases appear not to be vital in the absolute sense but require a long period of time to demonstrate their value that they may play the part of vitamins in the air, comparing the accessory food factors such as vitamin A and B with argon and helium. For these reasons it seems to us that a certain amount of leakage is desirable in enclosed systems such as that which requires an inflow of five to seven liters a minute of oxygen to maintain 40 to 50% oxygen in an oxygen tent, and in an oxygen room an inflow of ten to fifteen liters per minute. We have kept animals in an oxygen chamber for two to six months,[7] patients in an oxygen room for two to six months[8] and in oxygen tents from one to two months[9] without any signs of harm, maintaining a leakage range suggested above.

We have recently reported a portable oxygen chamber[10] in which it is unnecessary to use soda lime. The use of a rubberized fabric aids in the elimination of carbon dioxide because it has a relatively high permeability to this gas as contrasted to oxygen. Edwards and Pickering[11] found that carbon dioxide will permeate rubber fabric at the rate of 28 liters per square meter of rubber per 24 hours at 25° centigrade when exposed to a concentration of 100% CO_2. With rubber such as dental dam the permeability is increased to 42 liters per square meter per 24 hours whereas the permeability to oxygen is only 5 liters per square meter per 24 hours. The rate of permeability falls sharply as the partial pressure of carbon dioxide in contact with the rubber is decreased. In the portable oxygen chamber which has a surface area of approximately 50 square meters elimination of CO_2 through the rubber fabric might take care of from 1/5 to 1/3 of the CO_2 exhaled by an adult patient. The remainder of the CO_2 is largely disposed of through leakage. An inlet of 12-15 liters per minute in the oxygen chamber results in a washing out of carbon dioxide, with a replacement of fresh air. Even with two patients in the portable oxygen room the CO_2 has never accumulated above 1% when oxygen treatment has been carried on for a period as long as two months at a time. In order to administrate 50% oxygen and 3% CO_2 it has been necessary to add carbon dioxide from a tank. As the oxygen tent is ordinarily used, 6-7 liters

Improved oxygen tent with large ice chest and thermostatic control.

per minute of inflow of oxygen is required to maintain a 50% oxygen concentration. In our experience this has been sufficient to wash out most of the carbon dioxide exhaled by the patient so that we have not found it necessary to employ soda lime any longer. However, tests of the CO_2 concentration should be made routinely.

With the technical assistance of Mr. A. E. Davidson the oxygen tent has been modified in the following ways. The air cooler has been enlarged to have an ice capacity of over one hundred pounds. The motor blower is in a soundproof box below the ice chamber and is almost noiseless at ordinary speeds. In addition a thermostat is located in a duct between the tent and the cooling chamber. On the thermostat is a scale from 60-80° F with a hand wheel to operate the pointer. When the temperature falls below the desired level the motor slows, diminishing the volume of air to the tent. When the temperature rises above the desired level the motor is speeded up until the temperature is cooled to the set point. There are no rubber tubes, which avoids the possibility of kinking. The tent frame is on a movable joint which is easily elevated over the head of the patient and the tent fabric tucked in around the patient as formerly used. There is an additional switch which throws in a large volume of air and is capable of cooling the tent down to any temperature desired within a few minutes. Ordinarily the thermostatic switch alone is operated. The ice has to be refilled only every twelve hours. The picture shows the essential points. The volume of air delivered may be varied from 3 to 45 cubic feet per minute.

SUMMARY

Various factors involved in the ventilation of oxygen tents and oxygen chambers are discussed. The importance of providing a healthful air atmosphere in addition to an increased concentration of oxygen is emphasized. A modification of the oxygen tent is described in which a thermostatic control of temperature is achieved.

PRESENT AND NEEDED HEALTH SERVICES IN MONROE COUNTY*

By JOHN LIVERMORE HAZEN, M.D., BROCKPORT, N. Y.

THE recently proposed Public Health Law has aroused a new interest in, and stimulated a study of health administration throughout the State. Many of us were awakened from a sort of complacency to the realization that our various local health programs were falling far short of the possibilities included in the term "Preventive Medicine." State survey, also, showed a wide variation in methods and effectiveness of work in the various sanitary districts. Some excelled in certain lines of work, some in others, but few were carrying on a complete program of preventive health measures. Lack of organization, lack of funds, of public health nurses and of laboratory and hospital facilities were among the causes contributing to this inadequate service in many parts of the State.

The State of New York, greatest in wealth and population, certainly should be pre-eminent in this most important governmental function, that of conserving the health of its citizens, and that those living in remote and sparsely-settled districts are entitled to the same service and protection as is given to those living in centers of population is a basic principle of our government. If they are not getting proper service, how can it best be given them. The proposed Public Health Law attempted to answer this question and, while it was not enacted in its entirety, the attempt has proven salutary, for it has resulted in a State-wide demand for an administrative plan that will give uniform and effective service throughout the State.

To aid in the formation of such a plan, probably there is no organization so competent as is this Association of Sanitary Officers. In intimate contact with health conditions in all the various parts of the State, from the most remote to the crowded centers, and with years of administrative experience in their respective localities, the collective ideas of this body should offer constructive aid in the formation of a health plan for the State.

To invite discussion and study of the subject is the purpose of this paper, and to that end the essayist will suggest some requirements that seem fundamentally necessary to effective health work,

* Read before the Annual Conference of Health Officers and Public Health Nurses of New York State on June 30, 1931, in Saratoga, N. Y.

not only in the County of Monroe, but in any locality

First, a proper unit of administration Except as legislative boundaries, modern transportation has practically eliminated the border lines between adjoining towns and villages A family lives in a certain health district the husband works in another, the children attend school in another and their summer home is in still another, each under diverse and incoordinated health administration In determining a proper unit the County at once suggests itself, as it is a political subdivision having a central legislative body With its Board of Supervisors and other County officers very little added machinery would be needed to establish a County health Department Counties whose population and wealth are not sufficient to justify the support of a full health service might well join with another one or two counties having contiguous borders and establish an efficient central unit

Second, Organization Our study suggests the following departments

Administrative (a) A County Board of Health, among whose members shall be physicians from the district and a member of the Board of Supervisors The County Board of Health shall establish health regulations for the County and shall have general supervision of the County health program

(b) Local Boards of Health who may elect to continue as such and may enact local regulations under the rules of the County Board of Health

Executive A full time County Health Commissioner, appointed by the County Board of Health and a deputy from each local health district

Third A definite program, arranged by the County Board of Health and the County Commissioner, systematizing health education and covering clinics such as toxin antitoxin, small pox vaccination, prenatal, preschool, venereal, cancer, dental orthopedic, etc, clinics in which, so far as possible, local physicians would be utilized and paid for their services

Fourth A County Laboratory under qualified administration

Fifth A department of Public Health Nursing One or more County supervising nurses and local nurses distributed throughout the County, eventually approximating one to each five thousand of population

Sixth A Department of Sanitation, charged with the care of water and milk supplies, sewage and other physical problems

Seventh Tuberculosis hospital facilities available, the case-finding and follow-up directed by the County supervising nurse, and done by the local public health nurses, rather than by special nurses working from the hospital

The foregoing broad outline is intended to suggest a means by which the various local units, coordinated and acting under a central government, could set up collectively a service which no one local unit could accomplish individually

The question now arises, what would be the relation of the State to a program such as herein suggested? As to expense, both the present and the proposed Health Laws provided that the State pay one-half the cost of the budget under plans not essentially different from that outlined in the foregoing To find the expense to a district we have made careful estimates in Monroe County We have a population of 95,000 outside the City of Rochester, and we find that with State aid the County would save approximately $13 000 annually under the County Plan

Except for tuberculosis control, the cost of which varies widely in different localities, one dollar per capita is considered sufficient for a full health service

Regarding State control under a County plan The State Department of Health with its Public Health Council would formulate a general County plan, sufficiently elastic so that each County might adapt it to its own particular requirements, it would establish the qualifications necessary for the County Commissioner and the deputies, it would maintain constant supervision and contact with the State through the County Commissioners, collaborating and analyzing the statistical and epidemiological data furnished by them, it would maintain its various departments for consultation and assistance when requested by a County Commissioner

The State, then, would assume the relation that it now bears in the care of tuberculosis and insanity Instead of being a step toward State Medicine," in this plan the State relinquishes much legislative and executive function, delegating it to local governments

The Department of Sanitation of Monroe County has operated under this plan for three years, the State paying one half of our annual budget of $22,500 That it is working successfully is evidenced by the fact that we have applied to have our County Laboratory service put under the same plan The State requires only that which we ourselves demand—that the administration be competent and that the service be effective

This outline is submitted to the Sanitary Officers' Association for discussion and in the hope that each member will consider if a plan along these lines would meet the needs of his own County Details purposely have been omitted If a general plan can be agreed upon it can be easily adapted to meet special conditions

Unquestionably a new health bill will be written, and no more constructive work can be undertaken by this Association than the study as to what the bill should embody

THE PRESENT STATUS OF ACUTE APPENDICITIS IN A GENERAL HOSPITAL*

By PLIMPTON GUPTILL, M.D., AND JOHN J. MORTON, M.D., ROCHESTER, N. Y.

From the Department of Surgery, University of Rochester School of Medicine and Dentistry, Rochester, N. Y.

IF there be need for an excuse in talking on such a trite subject as appendicitis let us remember Virchow's statement that the younger workers' knowledge at best covers from three to five years. Publications of five years past do not exist for them according to this world renowned authority. The teachings of the master surgeons of the early part of the century have been largely forgotten by the rising generation as the enthusiasm for the newly discovered pathological process, its early recognition and cure have subsided. The members of the profession who were exposed to the debates which were bitter and hard fought, came to accept the facts as finally established. These facts now appear to them as so commonplace that there is a natural hesitation in further drawing attention to them. The result is that neither the laity nor the profession is as alert to the dangers of delay as they once were when publicity was given to this problem. And there is now need of a prophet like Murphy who will prefer perhaps to shout his message not from the housetops but over the radio with the assurance that he will thus reach a larger audience.

The evidence is convincing that appendicitis is not being diagnosed as early and consequently not treated as well as it was twenty-five years ago.[1] It is only necessary to review the mounting mortality rate per 100,000 population as given by Willis[2] to realize that the percentage increase of 30.9 per cent should not be regarded lightly. It is exceptional now to get statistics from the large general hospitals which show a mortality of less than 6 per cent or 7 per cent. But Murphy[3] claimed in 1904 that "the man who is having more than three or four deaths in a hundred operations for appendicitis is either receiving his patronage from incompetent or procrastinating medical men or he is doing too much manipulating in the peritoneal cavity under unfavorable pathological conditions."

We thought that it might be of interest to review the admissions for acute appendicitis to a general hospital over a period of one year in order to estimate how well the hospital is being served by the physicians in its neighborhood and how well the hospital in turn is serving the profession outside.

This report is based on a study of 113 consecutive cases of proven acute appendicitis operated upon at the Strong Memorial Hospital during the one year prior to May 15, 1931. This includes all cases with this diagnosis treated at the hospital. No cases were denied operation. During this same period there were also admitted to the service 79 patients presenting evidence of appendiceal disease. The histories and pathological examination in these cases indicated an interval, subsiding or non-suppurative stage, whereas the cases included in this report showed definite macroscopic and microscopic evidence of acute inflammation.

These patients were referred to the hospital from the City of Rochester and surrounding towns within a radius of fifty miles, being commercial or agrarian in their pursuits in about equal numbers.

Treatment was administered largely by the resident staff of the hospital with advice from members of the department of surgery of the University of Rochester. A fairly standard procedure was followed in therapy, this being in essence early operation, postoperative hypodermoclysis of normal saline, narcotics, low Fowler's position and only fluids by mouth in small amounts during the early convalescence.

It is intended to restate the common symptoms of acute appendicitis only sufficiently to contrast the infrequent manifestations. It is due to these, we believe, that much delay and mismanagement of this potentially lethal disease is incurred. Bower has shown recently that "the time that elapses between the onset of symptoms and operation and the mortality rate are constant as shown by comparative percentages."

In these 113 patients age limits were from 1½ years to 64 years. There was a gradual increase in the number of patients of an age up to puberty, a slow decrease from puberty to forty with relative sharp drop to 65 years. The largest group falling in a single five-year period was from 10 to 15 years of age. Children will be termed patients ten years of age or younger. Twenty-three such occurred in this series or twenty per cent of the total.

Fifty-eight of the entire series showed evidence in the gross at operation of perforation of the appendix, fifty-five were considered unruptured. In fourteen cases with no macroscopic evidence of perforation, positive cultures were obtained from the abdominal fluid removed on opening the peritoneum. The percentage of perforation in all the acute cases treated at the hospital was 51.3 per cent. Perforation had occurred in twenty of the twenty-three children treated or 87 per cent.

We have found that 73 hours had elapsed, as an average in the entire group from the onset of the first symptom until hospital admission. Twenty-nine cases were admitted after 96 hours or four days. What was the cause of this delay?

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 3, 1931.

What transpired during these three or four days of illness? It will be shown that not all were without care. In fifty-three instances it was possible to determine the amount and type of medical care. The average time elapsing from onset of symptoms to hospital entry was 60 hours in these 53 cases, a decrease of 13 hours over the average at large. However, the average time from the first symptom to first medical visit was 31 hours, leaving an average of 29 hours of medical care at home. In the group of 23 children 119 hours elapsed before hospital admission, with an average of 54 hours of medical care in twelve cases attended. Delay in hospitalization is markedly greater in children than in adults. It is worthy of mention, however, that 34 of the 53 cases receiving careful medical attention entered the hospital directly after the first visit by a physician.

The study of complete histories reveals that the symptomatology of acute appendicitis is not always classical. The onset as characterized by gradual epigastric or perumbilical pain was present in but eighty of 113 cases; five had sudden epigastric and two sudden right lower quadrant pain; five had intermittent cramps; eight had onset with general malaise; six with nausea; two with vertigo; one each with chill, and diarrhea; three, all in children with vomiting. Except for vomiting no predominance of the unusual presenting symptoms was noted at any age.

Abdominal pain, usually dull, lasting for several hours with little variation in intensity is the most constant, reliable symptom of acute appendicitis. It was present in 96.5 per cent of our cases, entirely absent in four cases. It occurs a few hours after the initial symptoms. It is not always present at the first medical visit, or at hospital entry. The apparent complete absence of pain was observed twice in children of two years, once in child of four years, once in patient of 17 years, all ruptured at operation. In eleven instances, pain radiation was observed. It was noted extending to the right lower back in seven, twice to the right lower quadrant of the abdomen, once each to the right upper back and posterior portion of the right thigh. Perforation was present at operation in seven of the eleven;—the occurrence was wholly in adults. Marked intermittent variations in intensity were noted in eight, perforation being present in five, one of whom was a child.

Vomiting was present in 86 of the cases or 76 per cent. It usually occurs during the first day; the average was ten hours after the appearance of the initial symptom. It is relatively more reliable in children, being present in 91 per cent of the cases. Seven of the 27 patients who did not vomit showed perforation at operation; nausea usually precedes vomiting. It was absent in 29 instances.

Persistent constipation has not been a constant symptom in our series. One hundred and seven patients gave a reliable history in this regard and of these 46 or 43 per cent had had unrelieved constipation, 24 had the usual bowel activity; eleven had spontaneous diarrhea; sixteen had diarrhea following catharsis. The eleven cases of early spontaneous diarrhea represent 10 per cent of the total cases. These patients had an elapse of time, on the average of 187 hours or 8 days from initial symptom to the hospital. This is three times as long as the corresponding interval when constipation was present. Unripe fruit had been ingested preceding the initial symptom in five cases; diarrhea in all members of the family was present once; three patients had backache, chills or weakness. One patient was known to have ascaris infestation previous to his present illness. Ten of the eleven were ruptured, six of whom were children; the one unruptured was an 18-year-old male who had chills, white blood count of 7,400, with a gangrenous appendix removed 40 hours after the initial symptom. Bowel movements had been produced by catharsis in sixteen instances; in 33 cases catharsis was ineffectual. Castor oil was the most common drug, having been used thirteen times, eight times in children, the administration in these instances being wholly by the parents. Perforation occurred in nine of these thirteen cases. Magnesium sulphate was employed five times, other laxatives were given in eighteen cases. Enemas were used thirteen times. The occurrence of a chill is considered uncommon in appendicitis. It was noted in eleven individuals, all adults, during the first 36 hours after onset; at operation rupture of the appendix was found in five of the eleven.

Urinary disturbances were noted on nineteen occasions, thirteen times manifested as pain on voiding, three times as frequency. In one case dysuria antedated abdominal pain by several days. White blood cells appeared twice, red blood cells once in the urine in moderate numbers. Perforation was present in only nine of these individuals. The age was universally more than ten years.

Other unusual findings recorded were: pain on extension of the right leg noted seven times, five of which were with perforations. Because of the difficulty in walking or lying flat in bed patients mention this early in their history. Macroscopic blood in the stool was observed by two adults. Prolongation of menses was noted in girls of 13 and 16 years. Pain on defecation and in male external genitalia were each present once. Loss of weight, 20 pounds or more, had occurred in three adults directly preceding the attack.

Previous attacks, similar in symptomatology to the present illness, were present on one or more occasions in thirty-four patients. Fifteen had had multiple attacks with a few months interval during the one or two years preceding

hospital admission; only two of the nineteen with a single preceding attack showed this to be earlier than the preceding year. The incidence of perforation was 41 per cent in this group, definitely lower than the percentage in patients with operation during the first attack.

The diagnosis of acute appendicitis is not always easy from examination of the patient. Cardinal signs which can be elicited at certain periods may be minimal at the time of examination. We have found the vital signs of temperature and pulse, normal in 13 of 113 patients. This finding was observed only in adults; three presented perforation at operation performed shortly after. The white blood count was markedly elevated in all but two. This group includes chiefly early arrival at the hospital, several being admitted less than eight hours after the appearance of the initial symptom. Equally unexpected are the marked elevations such as temperature 39° C., pulse 100 or more, and six to ten points increase in respiration. Such changes as these were noted in twenty-one patients, four of whom had temperature of 40° C., eight, a pulse of 120 or more. Children occur in ratio of one to two to adults; perforation was present in all but three; and with three exceptions, not limited to unruptured cases, the white blood count was elevated to 14,000 or more. Bacterial examination showed organisms present in the abdominal fluid in every case. Except for three patients seen at a later stage of the disease, this group were all first seen in the period extending from the 26th to the 96th hour of the disease; high temperature and pulse are coincident with bacterial invasion of the peritoneum. One death occurred three months after appendectomy following repair of a released entero-caecostomy. These patients as a group can fairly be termed the sickest of our entire series.

The second cardinal sign of acute appendicitis is abdominal tenderness. Localization at McBurney's point or in mid-right lower quardant was noted in 105 cases, 93 per cent. Two patients showed no abdominal tenderness. Three had maximum tenderness in left lower quadrant, one at the umbilicus, one maximum in right flank, one tenderness without localization. All eight patients without marked tenderness in right lower quadrant were perforated at operation. Two of these were children. Recovery was satisfactory in all.

Gentle percussion often aids in localization of maximum tenderness especially in acutely tender or hypersensitive patients. This was found positive in forty-two of the fifty-eight ruptured and in twenty-nine of the fifty-five unruptured cases. Pain caused in the right lower quadrant by pressure elsewhere in the abdomen is termed referred tenderness. This phenomenon was elicited fifteen times in appendicitis with perforation and twenty without perforation. Pain caused by release of abdominal pressure was manifest in 61 per cent of cases, being present in ruptured and unruptured in equal percentages. Percussion, rebound and referred pain are auxiliary in localization only.

Spasm of the abdominal muscles was entirely absent in 21 per cent, in essentially equal percentage of ruptured or unruptured conditions. Spasm when present corresponds favorably with the point of maximum tenderness.

Lower abdominal mass was palpable in nine instances in the mid-right lower quadrant; twice in suprapubic area, and twice in the mid-left lower quadrant. In no unruptured case could the inflammatory reaction in or around the appendix be palpated through the abdominal wall. Rectal tenderness could be elicited in 80 per cent of the cases, usually more marked on the right. Fullness in the cul-de-sac of Douglas or a definite indurated tender mass was observed in nineteen cases.

Another constant sign found in acute appendicitis is elevation of the white blood count. Ninety-four per cent showed increase above 10,000. Except in isolated instances the count is between 12,000 and 25,000. A low white blood count was observed three times in ruptured cases, one of which was an actual leukopenia of 2,900; we have not observed that a low count is necessarily an indication of unfavorable prognosis, as there were no deaths. Elevations of the white blood count above 25,000 were observed in nine instances, the highest being 42,000 obtained in a child, six years of age with a history of thirty hours duration, the appendix being unruptured. Seven of the nine were perforated usually with abscess formation. There is inevitably moderate, never high, febrile reaction. Early adolescence is the age exhibiting this reaction, the average being thirteen years.

Removal of the appendix with drainage, when indicated, was accomplished by either low right rectus muscle splitting approach or by oblique incision through McBurney's point. The former was used on 39 patients, the latter on 74. The appendix was ligated, and removed in every instance. The cauterized stump was inverted by means of silk purse string suture in 105. Drainage was instituted at the time of operation in 52 cases.

Cultures of the abdominal fluid were obtained on opening the peritoneum in 104 cases. Bacillus coli communis was isolated in 49 cases, Bacillus melaninogenicum was found 14 times, 12 of which were in the presence of B. coli and twice with non-hemolytic streptococci; never isolated singly. B. Welchi occurred once with B. coli. Streptococci were present on seven occasions, three each as viridans and non-hemolytic, once as hemolytic; staphylococcus albus was isolated three times and staphylococcus aureus once;

B. pyocyaneus and B. Freidlander were each present on single occasions. In no instance was the B. coli observed in association with any of the cocci groups. Macroscopic perforation of the appendix was present in more than fifty per cent of the patients showing positive cultures of the cocci group. This would not substantiate the theory that the cocci are early invaders subsequently replaced by B. coli, this replacement not being observed in these patients at least.

Similarly it was noted that organisms were present in the free abdominal fluid in fourteen patients in whom at operation, no rupture of the appendix could be found; in this group B. coli was present nine times, B. pyocyaneus once, and the cocci group four times. The so-called "miliary perforation" of the appendix occurred in twelve percent of all cases showing acute inflammatory condition. The organisms present were closely analogous in type and percentage to those observed when macroscopic perforation was obvious.

We have not yet determined the value of bacterial studies in the ultimate prognosis. Many of the complications of early convalescence, however, can be foreseen. Two, of the fourteen cases presenting "miliary perforations" of the appendix, showed peritonitis of the lower abdomen for two to three days postoperative as evidenced by temperature and physical findings. Six of the cases developed an abscess between the skin and peritoneal layers of the wound, this being the obvious site of the complication on either the third or fourth postoperative day. Abdominal drainage had not been instituted at operation in any of the cases. Removal of a few skin sutures with insertion of rubber drain is sufficient for healing. One patient who had been operated upon in the 14th hour of his disease showed "miliary perforation" with positive B. coli culture developed a secondary abdominal abscess on the 14th day. Operative drainage was necessary. All of this group had otherwise a satisfactory recovery.

In ten instances residual abdominal abscesses developed. Eight of these had macroscopic perforation at operation and had had adequate drainage instituted at the time; one patient had miliary perforation, one had neither perforation nor organisms free in the abdomen; in nine instances the abscess was evident between the 12th and 17th postoperative day, in one on the 43rd day. Nine were located in the pelvis or right iliac fossa, one in the left subphrenic region. B. coli was present in eight; B. Freidlander in one. The cocci group did not contribute to the formation of abdominal abscesses. Operative drainage was instituted in all. Recovery was satisfactory except in one who died three months after appendectomy from the effects of an extensive intestinal obstruction.

Twenty-nine other patients showed postoperative complications exclusive of peritonitis which was inevitably present in varying degree in all macroscopic perforations. Complete mechanical obstruction of the intestine developed in three patients, 12, 22 and 44 years of age. Paralytic ileus was present in five, early in convalescence, while mechanical obstruction occurred early in the second week. Broncho-pneumonia was present six times, activation of pulmonary tuberculosis once, minor pulmonary complications five times, otitis media twice and each of the following was observed once: gonorrhea, salpingitis, fibroid uterus, passage of ureteral calculus, Meckel's diverticulum, marked diarrhea, chicken-pox, thrombo-phlebitis of the femoral vein, and acute mastitis.

Healing of wounds was by first degree intention in 43 cases, by third degree in 63 cases. The average period of hospital convalescence for undrained cases was fourteen days; with drainage 26 days. Purulent abdominal drainage ceased on an average by the 22nd day.

Seventy-seven patients were followed in the Out-Patient Department for an average of 47 days. Satisfactory convalescence was complete in this time. There was no occurrence of fecal fistula at the site of the appendiceal stump. Weakness of abdominal wound was noted twice but herniation had not occurred in any patient.

It is evident from this study that the diagnosis of acute appendicitis is made only after rupture in about half of the really acute cases. In children the chances seem to be about seven to one against a diagnosis before rupture has occurred. Murphy's statement is as true today as it was in 1904, when he claimed that "every death from appendicitis is chargeable directly to the people, either for not calling in the physician sufficiently early after the onset of symptoms; or to the physician and surgeon for not acting promptly when they are called."

There is no royal road to the diagnosis of acute appendicitis. Many of the patients especially when seen early are exceedingly difficult to diagnose. But if the physician is "appendix-conscious" in dealing with any case of abdominal pain he will be less likely to overlook or mistreat it. The most consistent symptom in our study has been spontaneous abdominal pain. The most consistent signs have been localized tenderness on palpation of the abdominal wall; or tenderness by rectal examination; and an elevated white blood count. It is well to recall Richardson's statement[4] that peritonitis in males under 40 years is likely to be appendicitis in 90 per cent. It is well to remember that acute appendicitis is the most frequent cause for spontaneous abdominal pain. It is an advantage to regard every undiagnosed abdominal pain with suspicion until proved not to be appendiceal in origin. It has been our experience that the pelvic situation of the appendix has protected it from palpation in a certain num-

ber of instances. In such individual the value of rectal examination cannot be overestimated. Rectal tenderness associated with abdominal pain in the male is practically pathognomic for acute inflammation of the appendix, if acute prostatitis can be ruled out, as it easily can. Rectal examination in children is also of great value because of the shallowness of the pelvis and the accessibility of a relatively large area for examination. We do not agree with the observers who report that the white blood count is of no value in estimating whether the patient has acute appendicitis. It is a simple, rapid test which gives valuable information but it must not be done in a slip-shod fashion. We suspect that when it has consistently failed in some clinics that it has been because of some such reason. In children the history of pain may not be obtained or it may be denied by the child through fear or for some childish whim. But close questioning will reveal that the child has been restless, fretful, sleeping poorly, or crying, indicating pain by his actions. There is often a pallor present. Any gastro-intestinal upset in children when there is no evidence of trouble in the ears, throat, kidneys or lungs should be regarded as potentially appendicitis till proved otherwise. Finally there is a group of patients in whom the history and examination has failed to support a diagnosis typical for appendicitis but about whom the physician is worried. In such individuals it is our feeling that it is safer to explore, for the risk of operation is overbalanced by the risk of a wrong diagnosis. It is a gamble in such instances, of two weeks against a life perhaps. We have not had a fatality in this class of case in our series.

In our series of 113 proved acute appendicitis cases there were four deaths, 3½ per cent. We look upon this figure as very good when it is recalled that over 50 per cent were ruptured at the time of operation. The mortality would have certainly been much higher except for the careful nursing attention and constant alertness in meeting the complications. One child, male, 1½ years of age, had been sick for 48 hours and had received castor oil before being admitted to the hospital. He died 12 hours after operation and autopsy showed general peritonitis, bronchopneumonia and otitis media. The second death was in a girl of 15 years, sick for 96 hours; who came in after sitting up for a fifty-mile drive in a car. The condition was bad and the child was poorly prepared for operation which should have been delayed. Death occurred within an hour. The autopsy showed general peritonitis and partial intestinal obstruction. The third death was in a 17-year-old boy who had been sick for ten days. His attack began with diarrhea. After three days in bed he got up and worked about the farm for the next three days, after which he went to bed again. He showed a large abscess on the left side of the abdomen at operation. Death was due to paralytic ileus and general peritonitis according to the autopsy findings five days later.

The fourth death occurred in a boy of twelve years who had been sick for 48 hours, who had had castor oil and was very acutely ill at the time of entry. Operation revealed a general peritonitis from a ruptured appendix. He had a series of residual abscesses which formed in the peritoneal cavity; and several acute attacks of intestinal obstruction. In each of these attacks his condition was critical. He lost weight till he became a skeleton. In an attempt to permanently relieve these obstructions it was necessary to take desperate chances. His general condition was too poor to stand the necessary procedure and he died three months after his entry to the hospital. Autopsy showed multiple intestinal obstructions still present in the pelvis from peritoneal bands and adhesions.

LUPUS VULGARIS OF THE NOSE AND UPPER RESPIRATORY TRACT. TREATMENT WITH RADIUM

By E. MARTIN FREUND, M.D., ALBANY, N. Y.

LUPUS VULGARIS of the nose and upper respiratory tract is a rather rare occurrence in the larger cities in the eastern section of this country. While formerly it was seen more often, the present high standards of sanitation and public health have greatly lessened its incidence, particularly in the urban districts. Lupus is more common in Austria, France, Russia and the Scandinavian countries. Occasionally though, from some unknown source this condition will present itself, and if unrecognized in the early stages will bring about considerable destruction of tissue before it is arrested or cured.

Lupus of the nose is a form of local tuberculosis of that region, almost always secondary to an invasion of the upper respiratory tract. It may occur primarily in the skin, but more often it affects the mucosa. The nasal involvement may manifest itself first at the entrance of the vestibule, *i.e.*, at the union of the nasal mucosa with the skin of the vestibule. From there it may spread in both directions with equal facility, invading the nasal cavity or the face, sometimes involving one more than the other.

Incidence—Lupus occurs between the ages of 12 and 45, rarely commencing before or after this period. However, it is often seen in later life, but in these cases it is the chronic form which marks the patient with disfigurations that will persist until death. The ravages wrought by this disease are often extensive and horrible. Lupus is seen more in females than in males, the proportion being about 3 to 2, and its greatest incidence is between the ages of 15 and 25, occurring usually in poor hygienic surroundings, but sometimes developing under better environmental conditions.

Etiology—The causative agent is always the "acid fast" or tubercle bacillus, the invasion being either primary or metastatic. Usually there is an association of a tubercular adenitis, the latter being of an acute or subacute nature. The tubercle bacillus may not be easily demonstrable but a careful scrutiny of cultures and biopsies followed by guinea pig inoculations will in the end confirm the diagnosis.

Paths of Invasion—Lupus is essentially a dermatological problem, and I am therefore confining my discussion to involvement of the nose and upper respiratory tract. The primary localization may be in any portion of this region. If the nose is involved first, then the initial lesion is in most instances at the junction of the skin of the ala nasi with the mucous membrane of the anterior nares. Again, in the primary nasal type, the earliest manifestations may be on the septal surface or along the middle or inferior turbinate bone. The area involved may be self-limited or the disease may spread along the interior of the nasal cavity, involving the entire mucosa lining it.

It may also spread externally, breaking down the soft tissue of the tip of the nose, eventually involving the collumela, upper lip and cheek. This extension may be in a median line, unilateral, bilateral or in all directions. As this disease spreads, the tissues involved become destroyed, with the following sequence of changes: first, hypertrophic granulations, then small nodule formations, and finally ulcerations followed by complete tissue destruction. The area of involvement may be small or quite extensive and is not necessarily continuous. The nares may be collapsed and the lower portion of the nose may become a large ulcerative bleeding mass that is at times most unsightly in appearance. There is always a tendency to crust formation which, on being removed, leaves a bleeding surface that is soon covered again by new crusts. When this condition is widespread it produces severe disfigurement, and renders the victim a social recluse, especially in the case of a female patient.

When the invasion attacks the interior of the nose the destruction of tissue is not evident externally. Here, inspection may reveal extension along the turbinates, the septum, the floor of the nose and the rhino-pharyngeal vault, even reaching the area of the eustachian tubes.

Symptoms—In the early stages nodular formations appear under the surface of the skin. These may not protrude for some time and either are absorbed or become ulcerated. These nodules first give the appearance of an apple jelly mass, are semi-transluscent and have elevated edges. In most instances they break down, resulting in shallow ulcerous patches containing purulent fluid. The surface of the ulcer tends to crust formation which, on removal, bleeds and discharges pus freely, being soon covered again with fresh scabs. The ulcerative process may be slow or rapid, in the latter case often involving large areas. The face and nose are most often attacked. One or both ala nasi may be invaded and the process destroys the skin, soft tissue, cartilage and mucosa, causing extensive exposure of the nasal cavity in some instances, and in most cases a very distorted and unsightly appearance.

The course of the lesion is progressive though not continuous. There are periods of inactivity followed by exacerbations, each time resulting in larger cicatrices. From a rhinological point of view it may be sufficient to say that when the nose is attacked by lupus, the process may extend along the mucosa of the nose, lips, pharynx, larynx, vocal cords and trachea. On the soft tis-

sues in the mouth and pharynx there results a formation of infiltrative papillomata, while the hard and soft palate will show ulcerations followed by distorted contractures and whitish scar formations, not unlike scleroderma in appearance. When the larynx is involved, the tendency is fortunately slow and self-limiting. Here ulcerations and pachydermia may be noted and the edema will produce hoarseness, dysphagia and sometimes dyspnoea. The voice in these instances will vary from a mild huskiness to a marked hoarseness, and in advanced cases there may be complete aphonia. Due to perforations through the nasal septum the patients will often exhibit a characteristic nasal intonation.

Diagnosis—In the diagnosis of Lupus Vulgaris of the nose the salient features are as follows:

1. Characteristic appearance of the nodules resembling apple jelly masses, the color not disappearing on pressure.
2. Its tendency to develop in adolescence.
3. Predilection to invasion of face and tip of nose.

Lupus should be distinguished from an ulcerating syphilide, epithelioma and scrofuloderma. In doubtful cases Koch's old tuberculin will aid as a diagnostic indicator. The case history, blood reaction, age of patient, manner of onset and appearance of the lesion will help in the differentiation.

Varieties or Classifications

Clinically there are 5 distinct types of this disease: hypertrophic type, atrophic type, ulcerative type, multiple disseminated type and miscellaneous type.

1. Hypertrophic—nodules are large and coalesce, forming hard plaques and tumors of various sizes.

2. Atropic—small nodules forming a yellow brown mass resembling "apple jelly" in appearance; the skin surface is even, though it may be scaly. The older the lesion the more widespread and destructive it is.

3. Ulcerative—ulcer formations occur in either of the above types. These areas secrete a purulent discharge and tend to considerable crust formation. These ulcers also may be discreet, coalescent or disseminated.

4 and 5. Multiple disseminated and miscellaneous types—seen usually in the form of serpigenous ulcers, with the nodules either small or large and either superficial or deeply imbedded.

Prognosis—Lupus of the face and nose is usually a chronic disease. With the advent of radiation therapy, the prospects for cure or limitation of tissue destruction have been greatly enhanced. Much depends on the stage of the disease, the extent of the involvement, the general state of health and age of the individual.

By employing radium, the Finsen light or the *x*-ray, as I shall describe under the discussion of "Treatment," the disease can be arrested early. Though recurrences may follow, the extensive disfigurements so common in former years can be reduced to an absolute minimum.

Treatment—The treatment of lupus of the nose and face is not limited to any one method. Efforts must be directed toward the promotion of proper hygienic environment. The dietary treatment of this disease has been emphasized very much of late. This is particularly true of the salt-free diet. Some dermatologists even go so far as to limit their treatment of Lupus Vulgaris to the complete elimination of salt in the patient's diet, claiming recovery and cure by that method alone. However, I am of the opinion that the dietary regime should be used in conjunction with a proper form of local therapy.

Surgery must often be resorted to in the treatment of this disease, especially in the early stage and when the lesion is small and accessible. In that case surgical diathermia seems to yield brilliant results accomplishing the complete elimination of the disease. For the more extensive lesions the curetting and cauterization of the ulcerated areas will often also produce excellent results. Local caustics have been and are still employed, but their effects are inferior to those of mono-polar fulguration and carbon-dioxide application. Radiation, however, has proven the best means of treating this disease. Formerly the Finsen light was used exclusively, being followed by *x*-ray therapy which has been and is still considered a specific by some authorities. With the advent of Radium emanation therapy, a better form of treatment has been evolved. While the *x*-ray is directly applicable to external lesions it must be said that radium can be more easily applied to the inaccessible regions such as the nose, buccal cavity, throat and larynx. In the application of radium the Beta ray yields better results on the superficial lesions, while the Gamma ray seems to be almost a specific for the deeper or inner lesions.

Needless to state, the patient's physical condition must be cared for at the same time, both in the form of local treatments and general constitutional tonics.

Description of Case—Miss J. M., first seen by me March 3, 1930, age 19 years; well nourished; 5 feet 4 inches in height; weight 141 lbs.

Chief Complaints—Hoarseness of a marked degree. Facial disfigurement involving the nose and upper lip. Suffers from mild frontal headaches which are not constant. Has a continuous collection of thick mucus in the back of her throat which she either coughs up or swallows. Aside from that she has no complaints except a dread of mingling with people due to her facial appearance. See Fig. 1.

FIGURE 1

Front view of patient when first seen. Note extent of tissue destruction of lower portion of nose and upper lip at naso-labial junction.

Past History—Usual exanthemata of early infancy. No serious illness in early childhood except numerous attacks of tonsillitis. Had her tonsils and adenoids removed under ether anesthesia 8 years ago. Was informed at that time that only a portion of each was removed as they were "too large." The remaining portions were removed a year later. Hoarseness developed one month after the first operation and very shortly thereafter the nose infection supervened. As the soft tissues became involved and destroyed, crusts formed and these in turn fell off, leaving a bleeding surface; then a thick yellow pus discharge would remain, till new crusts formed again. There was always more or less discharge present. In the beginning there was no pain but as the interior of the nose began to be congested, there was tenderness, especially on blowing the nose. When the hoarseness first developed she had considerable pain in the throat and some difficulty in swallowing, but later the discomfort disappeared. She had received various forms of treatment in the past 5 years, including several series of *x*-ray exposures, "hypodermic injections" and ultra-violet ray therapy. There has been no cure or relief from any of these attempts.

Physical Examination—The nose reveals an ulcerative mass, "apple jelly" like in appearance, covered with thick, light yellow crusts involving the entire tip, both alae, extending almost to the cheek border on the left side. The upper portion of the upper lip is also involved, the lesion coalescing at the nasolabial junction. The right nostril is collapsed and indistinguishable while the left nostril is completely destroyed and permits an easy view into the interior of the nose. This ulcerative mass is red in color and covered by hard thick crusts underneath which there is much pus. The remaining tissue of both alae is tense, swollen and red. The ulceration extends through the interior of the nose, both on the lateral and mesial surfaces. There is a perforation of the nasal septum as large as a five-cent piece, involving the anterior half of the perpendicular cartilage. The middle turbinates are not involved. The nasal mucosa is inflamed and hypertrophic in character. The throat shows much scar tissue formation and distorting contractures, not unlike rhino-scleroma. These scars are firm in consistency and of a yellow-white color, and are seen on the hard and soft palate, pharynx and larynx, involving the epiglottis and false vocal cords. The true vocal cords are not involved, their movements being normal during the phonation and respiration. Posterior rhinoscopy reveals similar cicatrices in the naso-pharynx but no ulcer formations.

Heart and lungs normal, no evidence of tuberculosis in the chest clinically and confirmed by *x*-ray pictures. Nose cultures negative for Diphtheria Bacillus. A biopsy was made from a portion of the epiglottis and subsequently the pathological report was as follows: March 10th—"A small mass of dense fibrous tissue, of elastic consistency, showing intense chronic inflammatory

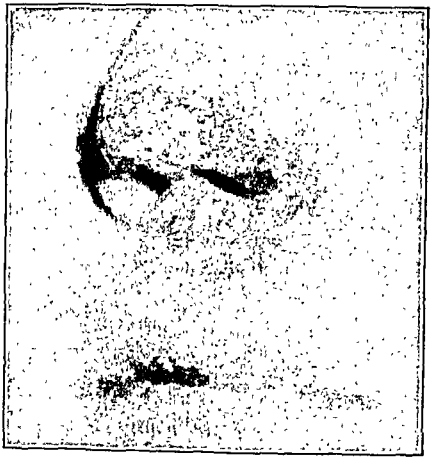

FIGURE 2

Shows new formation of tissue covered by epithelial islands, newly generated. Note also marked radium reaction of upper lip.

reaction. The surface of the tissue is covered with stratified squamous epithelium which in one place is slightly ulcerated. No true tubercles are observed but the reaction suggests tuberculosis." On March 17th a subsequent pathological report was as follows: "Tuberculosis dermatitis (Lupus Vulgaris). The tissue is intensely infiltrated with large mononuclear leucocytes and lymphocytes.

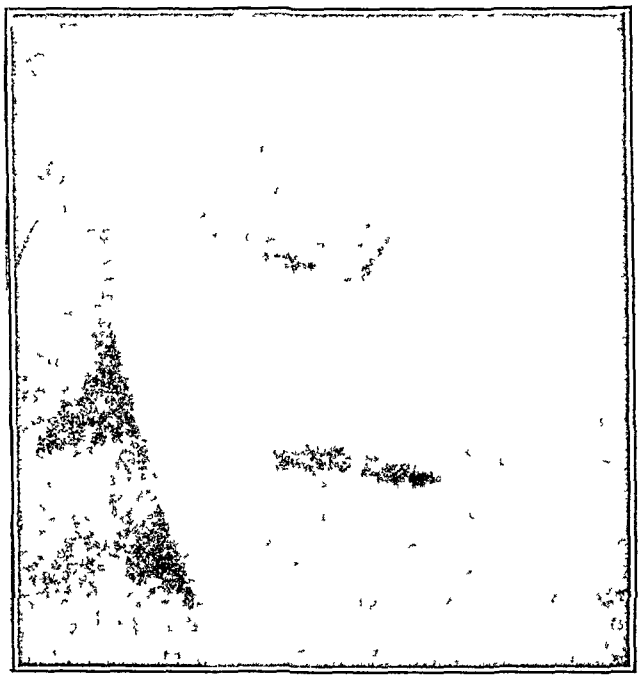

FIGURE 3

Scar tissue and granulations after partial plastic operation. These disappeared after several subsequent radium applications.

Foci of acute necrosis are also observed. A few typical tubercles are present." On May 5th the report of guinea pig inoculation was positive for tuberculosis. The patient's Wassermann report was negative and blood count was normal except for a slight leukopenia.

Radium treatments were instituted March 11th, 50 mgms. being applied for one hour to a selected area, at 10-day intervals properly screened for the Beta ray. Five such treatments were given in succession, the areas exposed being in the following order: left nares, columella and upper lip, interior of the nose and lastly right nares. For the interior of the nose only 30 mgms. were utilized.

There was no dermatitis or other undue reaction except on the upper lip which showed hyperemia and edema for about a month following this treatment. Fig. 2 demonstrates the gratifying effect of the radium two months after commencing treatment. By that time the patient's facial appearance was considerably improved and very shortly afterwards she discarded local dressings. A partial plastic operation was done to reshape her nostrils. Fig. 3 shows appearance imediately after this was done. The nasal mucosa appeared healthier and showed no tendency to crust formation. The patient felt better than she had for the past 7 or 8 years. Several applications of radium to the pharynx and larynx were subsequently made with marked improvement of the hoarseness as well as appearance of the mucosa. Fig. 4 shows the patient's condition on August 15, 1930, showing the disease practically cured.

Conclusions

1. Lupus Vulgaris of the upper respiratory tract is always metastatic, following a primary tubercular infection in the lungs, tonsils or the exterior of the nose. In the case above described the primary focus was situated in the tonsils.

2. The importance of a careful and detailed history plus modern laboratory diagnostic aids is stressed in the diagnosis of Lupus Vulgaris.

3. Radium therapy is by far the most efficient treatment, particularly in the regions that are inaccessible to surgery and *x-ray* exposure.

ROUTINE PROCEDURE FOR STUDYING ALLERGIC PATIENTS*

By KATHARINE BAYLIS MacINNIS, M.D., BINGHAMTON, N. Y.

MY object in presenting this paper is to suggest to you a practicable plan for handling your allergic patients. By "allergic" I mean those who have an altered reaction of the body to a foreign substance, whether it be purely protein or bacterial in nature. In this group I wish to include all of those patients who have hay fever, bronchial asthma, urticaria, angio-neurotic edema, eczema—especially in infants—gastro-intestinal hypersensitiveness or abdominal allergy, migraine, allergic bronchitis, certain arthritides, and bladder conditions.

When a patient presents himself for treatment, and perhaps says he has "hay fever," it is not sufficient to guess at the cause, but a very careful history and physical examination are most helpful before any protein testing or therapy is started.

Practically all investigators have agreed that 60 per cent of cases will show that one or more members of the immediate family has, or has had, some allergic condition. Heredity plays a most important part in the allergic patient. The careful family history which contains the information that a relative now has or formerly had an allergic manifestation does not mean that the same type of hypersensitiveness will be present in this patient. The child whose history reveals an allergic condition in both parents has a small chance of escaping some form of the disturbance at some time in life.

It is even more important to get a detailed personal history than family history. In taking the history there are certain factors that must be inquired into very closely, namely: the onset—as to time, new foods in diet, new places visited, new bedding, new pets—both live and artificial, new clothes—especially those which are fur trimmed, and various other things depending on the individual.

Two cases that are quite typical of histories are these:

The first was a little girl four years of age who had had attacks of asthma, always at night, and worse when she had eaten bread for supper. These attacks had been growing worse each year, and morphine and adrenalin were necessary to control them. She was tested to 125 foods, feathers, and a few animal proteins although she had no pet. Marked reactions were noted for feathers and wheat. She was given a kapok pillow to sleep on, and wheat was entirely eliminated from the diet. A report six months later showed that she had had only two attacks, once when she went to sleep in her mother's bed where there were feather pillows, and once when she had eaten a biscuit.

The other patient was the wife of a doctor—a woman about middle age. She had had eczema on her neck and wrists during the spring and fall for three years—purely seasonal. She was wearing a spring coat with a squirrel trim. On testing she was found negative to squirrel and strongly positive to rabbit hair. A special solution made from the fur collar gave a marked reaction, showing that the so-called squirrel was dyed rabbit. An interesting note is that her winter coat had a fox collar and this never bothered her.

Very often it is necessary to make a trip to a patient's home or place of business to study the surroundings which might have a bearing on the attacks. For some reason people will not give true information about these matters. Frequently dust of various kinds is the cause of the asthma or other allergic condition. The floor coverings, wall hangings, upholstery, bed clothes, animal houses or cages, dust from chicken houses, dust from places of employment, and so on, may be the offending agent.

I had one patient who had asthma due to the dust from woolen rugs on the floor. When cotton rugs were used the condition cleared. Another patient was sensitive to goat and horse dander, and when he visited his uncle who owned a goat farm he had asthma until he left. Still another patient had a most severe eczema on all the exposed surfaces, and legs, even though covered. Investigation of conditions and testing revealed the cause to be wheat flour dust from a flour mill in which he was employed. When given an outside job he immediately began to improve, and two weeks later the eczema was entirely healed.

Before beginning protein tests it is wise to have a complete physical examination and laboratory tests made. There are about 400 to 500 different proteins on the market used for testing. These do not include all the different ones made especially for patients from substances obtained locally. Very often the stock proteins will give no reaction, while a solution of local feathers, dust, or other suspected agents will give a positive reaction. Sometimes it is necessary to test a person to many proteins before the exact cause is determined. Often various types of testing must be used to verify the results.

The two main types of testing are the

*Read at the meeting of the Women's Medical Society, held at Syracuse, N. Y., June 1, 1931.

scratch method and the intradermal method. Some of the others are the patch method, the corneal or eye test, a passive transfer method which requires a third person, and a trial by diet, using first one food and then another. This last is most useful when there are repeatedly negative skin and intradermal tests.

Skin testing is used more generally than the other methods. The test scratches are located usualy on the inner side of the arm and forearm and the back. It is better to choose an area that is free from hairs. It is absolutely necessary to keep the tests in definite order so there will be no chance of confusing the readings. Usually rows of five or ten are made. The scratch is approximately one-fourth inch long and about three-fourths of an inch distant from the one just before and just following. Reactions depend upon the sensitivity of the individual skin, location playing only a minor role, and vary from a mild erythema to a wheal of varying sizes with pseudo-pods. Sometimes it is necessary to retest in various locations before the final diagnosis is made.

Treatment varies, depending on the type of case and the individual. In the purely food cases it is better to arrange a diet that is absolutely free from the foods that give positive reactions. If the case is due to eggs, milk, or wheat it must be remembered that just telling the patient to eliminate these is not sufficient, but that a detailed diet of all foods in which these are found must also be eliminated, even to the smallest amount.

In cases of pollen and animal hypersensitivity, if the offending agent cannot be entirely eliminated, desensitization must be effected, that is desensitization of specific allergens. All too frequently a "treatment set" which is not standardized and which contains one or more proteins of unknown strength is ordered for the patient. It is purely and simply an old "gunshot" prescription, and very likely to be the cause of poor results. Most of us today, I feel sure, believe in specificity of certain drugs, and in the treatment of allergic patients specificity is the most important thing if good results are desired. In using a "stock" or "gunshot" treatment set it must also be remembered that one is likely to cause a sensitivity to another pollen or protein to which the patient was negative at the time of beginning the treatment.

Desensitization by injection of specific protein therapy usually gives good results—60 to 90 per cent marked improvement or cures. This is accomplished by making a specific stock solution which is called standard or 1-50 solution. From this the other dilutions are made, and these different dilutions are used for testing. If the patient gives a reaction to the 1-10,000 dilution then a 1-100,000 dilution is made, and if no reaction occurs treatment is begun with this dilution in very small amounts, increasing until the patient is desensitized regardless of the size of the dose. After desensitization is once obtained it must be maintained for varying lengths of time, or until the body has become able to remain desensitized to the former offending protein without outside help.

Conclusions:

When a patient presents himself for relief of an allergic condition the first step taken must be a detailed history and investigation of all the angles of the case

In addition to the history a complete physical examination and laboratory tests must be made. Following these, from 50 to 300 protein skin tests are made by the scratch method.

After diagnosis is established treatment will depend on the case, necessitating either elimination or specific desensitization, or both.

Allergy is still so young and immature a specialty that one praises the results with caution, however a study of the available literature on the subject and personal work with hypersensitive individuals within the past few years convinces me of the great future in this field of medicine.

DEVELOPMENTS IN PUBLIC HEALTH ADMINISTRATION

One of the most important problems before the medical profession today is that of making all forms of medical service available to all classes of people The responsibility for giving the medical service is generally recognized as resting not only on the medical profession, but also on government officials and the citizens of the community Governor Roosevelt recognized his responsibility when he appointed a health commission to devise a coordinated medical service throughout the state

The recommendations of the Governor's Commission have to do largely with the duties of the state and the various communities While not much is said about the duties of the family doctors, yet they are recognized as essential for any

complete health service. While there is an undercurrent of feeling among doctors that the provisions of the health commission might lead to state medicine, yet actual experience with the laws that have been passed in the last year or two justify the assertion that family physicians are recognized as necessary in public health to a greater extent than ever before.

Physicians and public health administrators both need to keep in mind the fundamental principles on which medical service is rendered.

There are two parties in every medical service that is rendered.

1. The doctor.
2. The patient.

Whenever a doctor treats a patient he must consider two phases of the case:

1. The scientific principles to be applied to the case as an abstract medical problem.
2. The ability or inclination of the patient to carry out the directions of the doctor.

Medical science has advanced to such a degree of perfection that the majority of human ills and physical defects may be cured or prevented; but human nature remains as it was five thousand years ago, and patients often refuse to carry out treatments and public officials decline to provide hospitals, nurses, social workers and other means necessary for treatment.

A doctor deals with two classes of cases:

1. Those in which a doctor does practically all the treatment, as for example, dressing a cut, or administering drugs to a syphilitic case.
2. Those in which the patient carries out most of the treatment, as for example, diabetes and tuberculosis.

It is in the treatment of the second class of cases that a great part of the difficulty between the medical profession and government officials arises. If a man is earning only a thousand dollars a year and has half a dozen children to support, and is afflicted with tuberculosis, he cannot possibly obtain the proper food or take the proper rest unless he is helped by some outside agency. The medical profession has frequently been criticized for its inability to "cure" tuberculosis or chronic rheumatism. Treatment will be effective only when the community does its part in assisting the patient to apply the treatment.

The old method of dealing with sickness was that of providing for the patient and family after the sickness had fully developed. Charity has always been an appealing virtue, and people are quite willing to dispense help in the face of acute suffering. But dealing with conditions after they are fully developed is wasteful and inefficient, according to modern standards. The new way of dealing with sickness is to provide the means of treatment before the condition becomes advanced or incurable. The means of treatment are now considered to include economic and social aid as well as medical charity.

The burden of giving medical service until recently was borne almost entirely by the doctor in a two-fold way:

1. To give the actual scientific service.
2. To secure the means by which the patient could utilize the service.

When a doctor had to operate on a patient in the decade of the 90's, before hospitals were common, he often had to get a nurse, prepare a room in a private house for the operation, and see the poor officials for the food, and the church wardens for clothing. The doctor was the leader in charity and social work, as well as in medical service. Some doctors accepted this responsibility and others ignored it. One great development of medical service in these modern times is the provision for hospitals, public health nurses, and social workers, so that a doctor is relieved of the multitude of non-medical services which formerly had to be done by him or they were not done at all. Examples of the modern laws which compel the communities to do their part in giving medical service are the tuberculosis law and the welfare law. The welfare law, for example, states that the county shall provide medical service for those who are otherwise unable to obtain it. It recognizes the fact that there may be other reasons besides indigence for inability of a wage earner to provide medical service for his family. The interpretation of this law in several counties has been that the community shall remunerate the family doctor for treating these cases.

There are two methods by which the community may provide medical service:

1. By salaried doctors paid by the community.
2. By utilizing family doctors, thereby enabling the doctors to treat these cases as they would those in their private practice

There are grave objections to salaried doctors, both theoretically and practically. The experience of Germany, England and other European countries is sufficient to condemn that form of practice. The tendency of the New York laws and customs is to utilize the family doctor as is shown by the welfare law, the venereal disease law, and the laws relating to crippled children.

When a government official or department provides medical service, the community may reasonably demand that the service be of a high standard of practice. For example, the intravenous administration of arsenicals, and the procedures in the diagnosis and treatment of poliomyelitis are both considered to be within the realm of expert service to be given only by those who conform to the standards of expertness.

The adoption of proper standards of medical service is considered to be the prerogative not only of the doctors themselves but also of governmental bodies, especially departments of health. The ideal results are obtained when both the doctors and the governmental bodies meet in friendly cooperation as in New York State. The great accomplishment of the Committee on Public Relations of the Medical Society of the State of New York is that it has brought about the happy coordination of the medical profession with government officials and lay health organizations. If there are misunderstandings, a very large proportion of responsibility rests on the doctors themselves. They are the experts and should advise the government officials and lay organizations in their dealings with practitioners of medicine. A great field of medical societies is to secure this harmony and coordination of action.

The public health laws which have been passed recently have said very little about the duties and responsibilities of physicians, for the law-makers rightly assume that family doctors will do their part, both in the treatment and prevention of diseases, provided they are given the tools and other means of working. The Governor's Health Commission deals principally with these activities which the community is expected to carry on so as to enable the family doctor to give medical service to all classes of people. There are two methods by which the community may approach this problem:

1. By means of authority from above.
2. By means of evolution from the ranks of practicing physicians.

The members of the Health Commission have been like observers looking on a field of battle from a far-off height. They see the field of action like a general in command of a great army. Their conclusions have a very great value, and are respected by the medical societies of the State of New York.

The Joint Committee of the Medical Society of the State of New York is considering the observations of the Governor's Health Commission from the point of view of a soldier in the ranks. The responsibility for dispensing any form of medical service rests ultimately upon the family doctor; and his abilities, feelings, and customs must be considered.

The preliminary report of the Governor's Health Commission was printed in this Journal, of October first, beginning on page 1208. Several of its recommendations have already been enacted into law to the satisfaction of doctors generally. The major recommendation on which controversy is arising is that of a compulsory establishment of county boards of health in every county.

Since governmental officials manifest an increasing willingness to do their part in providing tools for giving medical service, doctors are inspired to renewed efforts to use those tools for the benefit of the public.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

Milk Education: Physicians who have begun to practice in the last decade know little about the long struggle to educate the people to demand pure milk and the milkmen to produce it. A pure milk special train today would be unnecessary, but a quarter of a century ago there was need for the one described in this Journal of October, 1906, as follows:

"The State of Maryland has a Department of Health and an independent citizen's movement, which are performing magnificent services for the people. The campaign against tuberculosis in that State has been most effective. Now it has turned its attentions to the milk problem, and is promoting a campaign of education of exceptional vigor. Besides the ordinary measures for encouraging and compelling the production of good milk, a 'milk special' was started out. This is a combination of a technical school on wheels and a political stumping tour. The train consisted of an engine and two coaches, one of which was used as an auditorium car. The territory to be covered was thoroughly advertised, together with the names of speakers and subjects. Farmers were invited to attend demonstrations and lectures at the stations at which the train stopped. Stops of forty minutes were made at each point. There were two speakers at each session. Each spoke for fifteen minutes and the audience was allowed five minutes to get into the car and five minutes to get out. In this way from fifteen to twenty stops were made in a day. The talks were published in the local papers, and were of such a character that make every word count.

"Such work as this is practical and profitable. The farmer can be shown how to produce good milk; he can be shown that it pays; and a demand for good milk can be created."

MEDICAL PROGRESS

Studies of the Mechanism of Upper Respiratory Infection.—A. R. Dochez, Katherine C. Mills, and Yale Kneeland, Jun., present confirmatory evidence that the primary cause of the common cold belongs to the order of ultramicroscopical viruses. They inoculated intranasally young chimpanzees, isolated under rigid quarantine, with bacteria-free filtrates of nasopharyngeal washings from individuals with acute colds. Within twenty-four to forty-eight hours the apes began to manifest signs of upper respiratory infection, sneezing, coughing, nasal obstruction, and a mucoid or mucopurulent discharge, which persisted for from five days to two weeks. Coincident with these symptoms, pneumococcus, *Streptococcus haemolyticus,* and *Bacillus pfeifferi* developed in greatly increased numbers and spread over a wide area of the nasopharyngeal mucous membranes. Similar experimental transmission of colds was then carried out in human subjects. The human experimental colds differed from those of the chimpanzee in that there was no immediate evidence of increased activity on the part of the potential pathogens harbored in the human nasopharynx. The authors describe the method by which they succeeded in preserving the virus of the common cold for as long as seventy-four days. The virus also reproduced itself *in vitro* when cultivated in a suitable tissue medium. The method employed was that of Maitland and Maitland and of Li and Rivers. In addition to initiating the symptoms of infection, this filterable virus may be considered to provoke increased activity of any potential pathogens that may happen to be present in the respiratory tract, and, furthermore, to render the respiratory tract susceptible to implantation by pathogenic organisms from the exterior. Studies conducted by the authors have shown, considering the respiratory year as running from September to June, that as this year advances there is an increasingly wide distribution in the nasopharynx of healthy individuals of the usual potential pathogens of the upper respiratory tract. It seems not unlikely, that as a consequence of the repeated cycles of common cold throughout the respiratory year an increasing opportunity is afforded the potential and secondary pathogens of the respiratory tract to cause infection. It may be that certain outbreaks of so-called influenza result from the coincidence of an epidemic of the common "cold in the head" with a period of wide distribution and greatly increased virulence of the well-recognized pathogenic organisms of the upper respiratory tract.—*The Lancet,* September 5, 1931, ccxxi, 5636.

The Progress of Nutrition.—In a review of the outstanding advances in our knowledge of nutrition, Francis Lowell Burnett emphasizes the fact that nutrition is the most important factor in the maintenance of health and longevity in man. McCarrison describes an unusually healthy people who inhabit a remote part of the Himalaya Mountains and live on the "unsophisticated foods of nature," and without meat. They are of magnificent physique, preserve until late in life the characteristics of youth, are unusually fertile and long-lived, and are endowed with nervous systems of unusual stability. On the other hand, McCullough observed a tribe in West Africa, whose diet consisted largely of cereal food, with only a small amount of protein and fat, both of poor quality. Among these people the infant mortality was high, lactation was seldom successful, and children and adults were short and underweight. The selection of an adequate diet in health and disease is comparatively simple. The normal requirement is 2,600 calories daily, the proteins supplying 10, the fats 30 and the carbohydrates 60 per cent. In addition an adequate amount of minerals and vitamins is essential, and the acid-base balance must be preserved. Stone considers the amount of sugar consumed by English-speaking peoples as excessive, but believes a protein intake of one gram per kilogram of body weight is not injurious. Minot points out that deficiency diseases occur in many and varied types, some of which are recognized after many years; that they may be the result of failure to assimilate the required factor, and that the lack of vitamin not only causes a particular disease, but plays a rôle in the economy of the body by its effect on certain functions and types of cells. Proper treatment requires a recognition of the relationship between the amount of substance a patient receives and the beneficial results produced. Diseases characterized by edema and cardiac swelling are probably caused by long continued deficiency with excess of fluid intake. The excessive increment of fat in the human body is undoubtedly due to malnutrition. In reducing the loss of two pounds a week is as much as should be sought, and one pound is quite enough after 10 or 20 pounds has been lost. Investigations have shown that the chemical character of the fat stored is unmistakably determined by the nature of the dietary precursors. Temporary diabetes can be produced in healthy persons by first reducing the carbohydrate and then giving it in excessive amounts. It has been proved that liver and iron are of definite value in hemoglobin regeneration in anemia. Desiccated and defatted

hog's stomach has proved as effective as liver in pernicious anemia In heart disease dyspepsia may be prevented and acidosis controlled by a diet low in calcium and the chlorides, and increase in the ingestion of sugar has a peculiarly beneficial effect A meat diet tends to increase blood pressure A high protein diet promotes wound healing An acid diet inhibits growth, depresses the serum phosphates, the alkali reserve and the pH, with a compensatory rise in the chlorides sugar, and cholesterol in the blood Rickets has developed in animals on an acid diet Ivy has shown that the hormones play a role in digestion There is evidence that an excess of protein in infants causes a very irritable colon, diarrhea, and acid stools Several investigators have shown that vitamin deficiency lowers resistance to specific infections The value of the ketogenic diet in epilepsy has been demonstrated Burnett also reviews the relation of diet to rickets osteomalacia, carious teeth and arthritis He mentions studies showing that vitamin A deficiency is the chief factor in producing lymphadenoid goiter A diet such as that of Hermanns dorfer and of Mayer and Kugelmass produces a definite improvement in certain tuberculous patients Sugiura and Benedict have found that cancer does not develop on diets deficient in vitamin A and that their rat carcinoma regresses when the animals receive an excessive amount of butter fat —*New England Journal of Medicine,* August 13, 1931, ccv, 7

The Failure of Liver Treatment in Hemolytic Icterus —J Neuburger says if the view so often expressed in the literature be correct, that the essence of pernicious anemia consists in a primary hemolysis with a secondary reaction upon the activity of the bone marrow, and that this primary agent of hemolysis can be overcome by liver therapy, it must likewise be true that hemolytic icterus would react to liver treatment On the basis of two case histories, however, he shows that this is not the case A study of these histories shows that the anemia of hemolytic icterus is very difficult to influence After administration of liver substance a temporary improvement in the red blood picture could be observed, but it had not proceeded far before it came to a stop In both cases the white blood picture was favorably influenced more promptly than the red, the number of white cells became approximately normal and the megalomacrocytosis was overcome The microcytosis however, was still less influenced than the number of the red cells and the hemolysis responded least of all In the first case there was free hydrochloric acid in the stomach so that the failure of the liver therapy might conceivably be connected with this, but in the second case there was achylia In neither case did the use of either liver extract or fresh liver have the slightest effect upon hemolysis Powdered stomach substance produced no better results It is impossible as yet to say whether in pernicious anemia the good effects of liver and stomach substance are exerted not upon the hemolysis but must lie in some other direction It could be seen, however, that the improvement in the white blood picture began before the liver was administered, whereas the hemolysis and microcytosis continued undiminished despite the liver treatment This raises the question whether hemolysis really constitutes a primary cause in pernicious anemia The author thinks it does not In both cases there was some improvement in the anemia under other forms of treatment notably iron and arsenic, but not of the hemolysis Not even after iron had improved the anemia and the white blood picture did further administration produce any modification of the hemolysis —*Deutsche medizinische Wochenschrift,* June 5, 1931

Reflex Tenderness A Sign of Gall-Bladder Disease —In the examination of a large number of patients for possible gall bladder disease, George Levene has observed that tenderness in the right subcostal area is a somewhat uncertain sign While a diseased gall bladder is always more or less tender, the difficulty in eliciting such evidence lies in the fact that the position of the bladder varies considerably in different persons and not infrequently in the same individual Thus a given point on the skin surface may, or may not, overlie the gall-bladder During radiographic examinations Levene has noted that tenderness on slight pressure over the right costovertebral angle is of frequent occurrence In the analysis of 100 unselected cases tenderness was found over this area in 92 3 per cent of patients showing roentgenological evidence of gall bladder disease It was absent in 95 7 per cent of the persons regarded as normal Of 13 patients operated upon, 92 3 per cent showed reflex tenderness, and the diagnosis of gall bladder disease was confirmed In order to elicit this sign, the patient is placed prone on the examining table, the arms by the sides The examiner places the middle finger and thumb, respectively, over the left and right costovertebral angles, and applies gentle pressure, first over the left side and then over the right He next explores the area from the tenth to the twelfth ribs, in a zone two inches from the spine, palpating left side first Tenderness due to gall bladder disease is invariably higher than that produced by disease of the right kidney The author is of the opinion that even lesser degrees of gall bladder disease can be detected by this sign —*New England Journal of Medicine,* August 20 1931 ccv, 8

The Three Different Rhythms Controlling the Heart.—On the basis of a case studied electrocardiographically for nearly 5 years, with tracings made at frequent intervals, Anna Francova-Helbichova says that disturbances of auriculo-ventricular conduction are the symptom of a lesion of Tawara's node and the bundle of His, which are unable to conduct the sinus excitation with the optimum speed. Because of this lesion there was an incomplete auriculo-ventricular dissociation, manifesting itself by a simple prolongation of the PR interval and by ventricular intermittences which appeared either regularly (2nd type of Mobitz's partial block) or irregularly (a block of 2:1). As a result of troubles of conduction and a hyperexcitability of the autonomic ventricular center, there appeared ventricular contractions of such a kind that a rhythmic production of ectopic excitations could be assumed side by side with sinus excitations. The sinus impulses could not affect these subordinate centers under cover of the incomplete auriculo-ventricular dissociation and of a defensive block which may be supposed to have formed around them. The phenomenon of interference of different rhythms was the more remarkable, in that, in opposition to the sinus rhythm, there were established not one but two rhythms of automatic excitations. The ectopic centers functioned in very slow rhythm (27-26). The distances between the ectopic ventricular contractions had a greater common divisor, which represents the time between two impulses of these subordinate centers. The author thinks a parasystolia must be assumed, in the sense of Weber and of Singer and Winterberg. According to these authorities, any given case is a parasystolia if it fulfils the following conditions: (1) The ectopic contractions start in a focus of ventricular excitation; (2) the frequency of these excitations is slow, in accordance with the weak physiologic automatism of the specific ventricular tissue; (3) the waves of excitation at the sinus point of departure do not disturb the rhythm of the ventricular center; therefore one may suppose that the latter is protected against the sinus wave (a block of defense); (4) the heterotopic contractions in ventricular parasystolia appear at very different intervals after the antecedent normal systole. This case meets these conditions and hence seems to offer an example of parasystolia of slow form.

Ectopic rhythms are not perfectly regular. Following a considerable oscillation of the sinus rhythm, the author would explain this irregularity according to Scherf and Weiser's theory, namely that a supraventricular ectopic rhythm may oscillate parallel with the sinus rhythm, since it is exposed to the same influence of the nerves of the heart as the sinus center.—*Archives des maladies du coeur, des vaisseaux et du sang,* June, 1931.

Diathermy.—E. P. Cumberbatch, writing in the *Canadian Medical Association Journal,* August, 1931, xxv, 2, describes the advantages gained by employing diathermy to heat the tissues; hot air, hot water, and other hot objects placed in contact with the skin, or at a distant point from it, heat the superficial tissues alone. Electric currents other than diathermy are quite unsuitable for the purpose, because they produce unbearable contraction of the muscles and dangerous chemical changes within the tissues. The therapeutic properties of the diathermy current are those of heat and of heat alone. The diathermy current relieves pain and spasm, aids the resolution of inflammation, assists the tissues in freeing themselves from infection and can be brought into regions which are beyond the reach of other thermo-therapeutic agents. In the treatment of certain pelvic diseases of women diathermy has made the most far-reaching advances. By introducing a special electrode into the urethra and completing the circuit by means of a pelvic belt electrode the part mentioned can be heated to 114° F., and freed from infecting gonococci in about 90 per cent. of the cases. The same is true of the cervix uteri when treated in a similar manner. If the infection is non-gonococcal it can be removed in about 80 per cent. of the cases. By means of a special vaginal electrode it is possible to terminate infection of the Fallopian tubes. Congestive dysmenorrhea can always be cured by diathermy, but the spasmodic type is only temporarily benefited. The prostate and vesicles can be subjected to diathermy by way of a special rectal electrode. This treatment always brings gonococcal arthritis and fibrositis to an end. In gonococcal epididymitis and orchitis its action is remarkable. In angina pectoris diathermy diminishes the frequency and severity of attacks, and a few patients appear to have been cured. The blood pressure, if very high, can be maintained at a reduced level for long periods. In mucous colitis diathermy is of high value, and by it the pain due to anal fissure can quickly be relieved. In both innocent and malignant growths the diathermy current can raise the temperature until the tissue proteins coagulate. By the use of the needle electrode malignant growths can be eradicated. It divides the tissues like a scalpel and at the same time coagulates the divided surfaces, thus sealing microscopic vessels. Large vessels are seized by forceps and the cut ends coagulated by the current, so that no suture is needed. Wounds made by the cutting current heal by first intention, and postoperative shock is less than after operation with the scalpel.

Experimental Studies in the Genesis of the Common "Cold"—Catarrh.—With a view to obtaining a better understanding of the common

cold, P Schmidt and A Kairies report that by means of delicate thermoelectric measurements they have succeeded in taking the exact temperature of different parts of the mucous membrane of the mouth and throat Using 36° C as a zero point, they were able after a little practice to record variations as slight as 0 03° C or even one half this amount The warmest portion of the mucosa was found to be the sublingual and tonsillar regions, the coolest the pharynx and palate After these various preliminary measurements, a uniform spot was chosen as a basis for comparison in different individuals, viz a point between the uvula and the lateral wall of the soft palate, about 1 cm from the margin of the palate, and as a rule on the left side Tests were carried out on 16 persons in the winter season, to find the reaction of the mucous membrane upon exposure to cold and heat The chilling experiment consisted of letting the subject inhale cold air for one hour at an open window, with the mouth open, after which the temperature of the mucous membrane was recorded The subject was then given a cup of hot coffee to drink, and a little later the temperature was taken again, both in the mouth and at various points on the skin In most individuals the degree of chilling was about the same, but the time required for warming up again of the mucosa showed wide variations in the different subjects The restoration of temperature was particularly slow in persons of asthenic type with great sensitivity to cold and a strong catarrhal tendency This time factor seems to be of peculiar significance for establishing the *types of reaction* In tonsillectomized persons the absence of the tonsils as "warm pillows" for the temperature of the mucosa is evidently an influential factor In most persons the drinking of a large amount of hot coffee quickly restores the normal temperature In some subjects loud speaking and singing, as a mechanical irritation, had a much more marked effect on the mucous membrane than did chilling, especially in cases of chronic tonsillitis and pharyngitis There was a relation found in some cases between chronic tonsillitis and the great group of hypersensitive states (asthma, bronchitis, hay fever, chronic joint rheumatism) Chilling of the feet produces distant symptoms in some subjects, suggesting that a vascular spasm occurs, which, in extreme cases, lasts long enough to stop all phagocytosis, while growth of bacteria continues —*Deutsche medizinische Wochenschrift*, August 7, 1931

Hyperfunction of the Posterior Lobe of the Pituitary as the Cause of Nephropathy and Eclampsia of Pregnancy —When the cause of the metabolic disturbances that underlie toxicoses is sought, say Friedrich Hoffmann and Karl Julius Anselmino, in the *Klinische Wochenschrift* of August 1, 1931, it is wise to begin with the study of milder cases rather than with cases of eclampsia accompanied by coma and convulsions, for these are nonspecific manifestations which may be found in all possible kinds of disease, and which accordingly explain nothing of the nature of the illness But we find metabolic disturbances in pure form in pre-eclamptic states, viz, in patients with hydrops and nephropathy Here the principal metabolic disturbance is the tendency to water retention In relating toxicoses to endocrine disturbances it will be recalled that the cardinal symptom, which is water retention, represents the characteristic effect of the antidiuretic component of the posterior lobe of the pituitary, which accordingly—probably by increasing the retrograde resorption of water in the tubules—produces in the healthy kidney a characteristic inhibition of diuresis This at once suggests that the increase of blood pressure frequently observed is in accord with the pressor action of the posterior lobe If we compare the other *important clinical manifestations in nephropathy* and eclampsia with the corresponding effects of the posterior lobe, we find nearly complete agreement Among these were increase of blood pressure and capillary spasms, appearance of coma, convulsions, pulmonary edema, diminution of galvanic excitability, definite displacements of ions from blood into the tissue, and the diminution of symptoms by means of very definite narcotics and hypnotics Quantitative determinations on the part of the authors established the presence of an excessive content of the blood in the posterior lobe, and a parallelism between the hormone concentration and the severity of the clinical manifestations These clinical symptoms are accordingly to be regarded as the result of a toxicosis of the posterior lobe of the pituitary It is thus shown that the renal symptoms and eclampsia of preganancy are attributable to endocrine disturbances, with the clinical picture dominated by an overproduction of the antidiuretic component of the posterior lobe of the pituitary, and in the cases with increased blood pressure by increased production of a pressor substance, which is presumably identical with that in the posterior lobe

LEGAL

AUTOMOBILE—RIGHT OF POLICE TO COMMANDEER IN AID OF ARREST

By Lorenz J. Brosnan, Esq.

Counsel, Medical Society of the State of New York

A citizen of the State of New York is driving his automobile on a highway or street in this State, when suddenly a police officer jumps on the running board and commands him to pursue a fleeing criminal. Must the citizen obey such command or, if he does not, can he be prosecuted criminally for such refusal? In the event that he obeys such command and is injured in the course of such pursuit, has he any redress in the civil courts for compensation based upon such injury or, if in carrying out this command he is killed, can his dependents obtain redress in the civil courts for his loss? In this age of racketeers and gunmen these questions are not academic. It is a common occurrence to pick up a daily newspaper in any of our large cities and read the gruesome details of a battle between the gunmen and the police, in broad daylight, upon the crowded streets of our cities and towns.

The police in the performance of their duty may lawfully call upon a private citizen for aid and assistance in order that such police officers may arrest any person or recapture a person who has escaped from legal custody. "The right of a peace officer 'to summon and require the assistance of as many bystanders as may be necessary to enable him to perform his duty in making an arrest or preventing or suppressing a breach of the peace,' as well as the obligation upon the bystander to obey, is firmly rooted in the common law. Like those summoned to form a posse comitatus, the bystander is bound to aid and assist."

Section 1848 of the Penal Law of the State of New York provides: "A person who, after having been lawfully commanded to aid an officer in arresting any person, or in re-taking any person who has escaped from legal custody, or in executing any legal process, wilfully neglects or refuses to aid such officer is guilty of a misdemeanor."

A few years ago a very interesting case arose in the Court of Appeals of this State dealing with the question under consideration. The case came before the Court upon the following state of facts: A man was employed as a chauffeur by a taxicab corporation. While driving one of its cars in the performance of his duty upon the public highway, a police officer jumped on the running board and ordered the driver to chase another car in order to arrest its occupant. Suddenly another vehicle cut across the path. The result was a collision from which death ensued. The chauffeur's widow filed a claim pursuant to the provisions of the Workmen's Compensation Law, claiming that her husband's death occurred in the course of his employment as a chauffeur for the taxicab corporation. The taxicab company contended that the death of the deceased did not arise out of and in the course of his employment, but was occasioned by the commandeering of the deceased and of the vehicle by a police officer.

After a hearing before the State Industrial Board, an award was made to the widow which was affirmed by the Appellate Division, and the taxicab corporation then took the case to the Court of Appeals. In affirming the award, Chief Justice Cardozo writing for the court said:

"'A person who after having been lawfully commanded to aid an officer in arresting any person, or in retaking any person who has escaped from legal custody, or in executing any legal process, wilfully neglects or refuses to aid such officer is guilty of a misdemeanor' (Penal Law, Section 1848). The duty goes back to the days of the hue and cry. 'The main rule we think to be this,' say the historians of our early law, 'that felons ought to be summarily arrested and put in gaol. All true men ought to take part in this work and are punishable if they neglect it.' The law did not limit itself to imposing upon the manhood of the country a duty to pursue. To make pursuit effective there were statutes in those early days whereby a man was subject to a duty to provide himself with instruments sufficient for the task. A typical illustration is a statute enacted in 1285. 'Immediately upon such Robberies and Felonies committed, fresh Suit shall be made from Town to Town, and from Country to Country.' Every man shall 'have in his house Harness for to keep the Peace after the antient Assise.' The amount is to be proportioned to the quantity of lands and goods. Thus, for fifteen pounds of lands and goods there shall be kept 'an Hauberke, a Breastplate of Iron, a Sword, a Knife, and an Horse.' We may be sure that the man who failed to use his horse, and who would only go afoot, would have had to answer to the King.

"The horse has yielded to the motor car as an instrument of pursuit and flight. The ancient ordinance abides as an interpreter of present duty. Still as in the days of Edward I, the citi-

zenry may be called upon to enforce the justice of the State, not faintly and with lagging steps, but honestly and bravely and with whatever implements and facilities are convenient and at hand. The incorporeal being, the X Taxi Corporation, would have been bound to respond in that spirit to the summons of the officer if it had been sitting in the driver's seat. In sending A upon the highway, it knew or is chargeable with knowledge that man and car alike would have to answer to the call. An officer may not pause to parley about the ownership of a vehicle in the possession of another when there is need of hot pursuit. In so far as the danger of pursuit was a danger incidental to the management of the car, it was one of the risks of the employment, an incident of the service, foreseeable, if not foreseen, and so covered by the statute."

One of the Judges of the Court dissented from the ruling of the Court of Appeals, holding that when the taxicab chauffeur, in obedience to a lawful command, gave aid to the police, he became himself a member of the police department and was no longer acting for his employer, the taxicab corporation, and hence his death did not arise out of and in the course of his employment. In the dissenting opinion it was said in part:

"The direction which he took; the speed at which he drove his cab—these became subject to the supervision and control of the policeman on the running board. Since, from then on, in all his movements, he must have yielded obedience, not to his original employer, but to the officer, he ceased to be a servant of the former and became a servant of the police department of the government. The argument that he remained the general employee of his original employer and a special employee of the police department is not tenable. All the cases dealing with general and special employment proceed upon the theory that the work of the special employment is performed at the instance of the general employer. Here the original employer was not aware that his employee had been impressed into the police service and, therefore, could not have given its consent or its direction that the services should be performed."

It thus appears that an employee working for an employer subject to the Workmen's Compensation Law, and his family are fully protected under the circumstances considered in this editorial; but this, of course, does not mean that a citizen driving his own car is so protected. The law does not give to him any redress in the civil courts against the municipality for an injury sustained in the course of assistance rendered to a police officer of such municipality nor, if death ensues, does the family of such individual have any legal redress against the municipality. It is true that the municipality may, and sometimes does, as a favor render assistance in such a situation, but the municipality cannot be compelled by law to do so.

In commenting upon the situation here discussed, one of the papers of this State stated editorially in part as follows:

"The legal, to say nothing of the physical, situation of a taxi driver who finds himself careering down a street with a policeman on the running board, his speedometer at sixty miles an hour and a fusillade of bullets imperiling his life is a matter not without interest. It becomes of even greater interest when one realizes that not only a taxi driver but any citizen who owns and drives a car may find himself in the same predicament. . . .

"Happily, commandeered drivers rarely stop to discuss the law with the policeman who hails them; ordinarily the citizen tears open his throttle and gives way to the excitement of the chase with a reckless courage fully equal to that of the police. If a hired driver, he can reflect as he goes that his compensation, at any rate, is safe. The private owner has to take his chances, though if his death should leave his family in want, the municipality would doubtless relieve them as an act of grace. And more timid souls can remember that if they refuse to obey the command, a misdemeanor involves a maximum penalty of only a year's imprisonment or a $500 fine."

HOT WATER BOTTLE BURN

A specialist in urological surgery was called by a general practitioner to the home of a patient who was suffering from an enlarged postate which prevented the emission of urine. The doctor examined the man, who was eighty years of age, and found that his general health was good and the doctor arranged to operate upon him. He placed the patient under an ether anesthesia, opened the bladder by making an incision in the abdomen and drained the bladder. He did not, however, remove the obstruction as he considered that that would be too much of an operation for a man of the patient's age to have done in one stage. He, therefore, inserted a drain and about ten days later, the man having recovered well from the shock of the first operation, the doctor undertook to complete the operation of removing the muscle which obstructed the ureter.

The operation was performed under a spinal anesthesia and all went well until just as the doc-

tor was completing the suturing up of the wound, one of the assistants notified him that the patient was going into shock. The patient who had been talking up to that time was gasping, and the doctor became apprehensive that he was about to expire. Hypodermics were immediately administered to the patient and a hot water bottle, which was handed to the doctor by a nurse, was wrapped by the doctor in a cloth and placed against the patient's abdomen about four inches above the point of incision. The doctor remained with the patient who in about five minutes revived and seemed to become normal again. He was returned to his room in the hospital and the hot water bottle was permitted to remain against his abdomen, since the patient had previously complained of being cold in that region. The doctor was informed the next day by the patient's nurse that a burn had developed at the spot where the hot water bottle was placed. The burn was dressed and healed without any difficulty.

Much to the surprise of the doctor, a suit was instituted charging that due to the negligence of the defendant doctor the patient had sustained a serious burn, for which large monetary damages were claimed. When the case came on for trial in its regular order, the attorney for the plaintiff failed to appear to try the case. On motion of the attorney for the doctor the action was dismissed by the presiding justice.

CLAIMED NEGLIGENT ABDOMINAL OPERATION

A young woman consulted the defendant doctor complaining of a burning sensation on urination and frequent urination together with a profuse vaginal discharge, and also severe pain on the lower right side of the abdomen. The doctor examined the patient and found a swelling on the right tube and ovary, with marked tenderness. A smear which was taken showed numerous pus cells. The doctor treated the patient practically daily for the next two months, at the end of which time the discharge had subsided and the acute symptoms had cleared up. The tube on the right side was still enlarged, so he advised that if she had any attacks in the future an operation would be the only cure.

Nearly a year later the patient returned to his office complaining of severe pain, so the doctor made arrangements for an operation. She entered the hospital and the operation was performed by another doctor, with the assistance of the defendant doctor, for the removal of the patient's appendix, part of her right ovary and part of her right tube. The defendant doctor attended the patient during her ten-day stay at the hospital which was uneventful. After her discharge from the hospital, he called at her home every day for the next week.

Apparently the patient on the first day after her discharge from the hospital got out of bed and walked to the bathroom in her home against the doctor's orders. The result was that a blood-clot formed directly over the incision. This was treated by the defendant doctor and promptly healed.

Sometime later the patient called at the office of the defendant doctor complaining of a slight discharge for which he advised a douche.

This was the last seen of the patient, and sometime later a summons and complaint were served on the doctor charging that the operation had been performed so negligently that a false growth and adhesions resulted and that the patient had been compelled to undergo a second operation. The doctor who actually performed the operation was not made a defendant, for apparently the patient had the false notion that the defendant doctor had performed the operation himself. The case was apparently a strike suit for, just as it was about to be reached for trial, the plaintiff's attorney agreed to discontinue the action.

NEWS NOTES

AMERICAN PUBLIC HEALTH ASSOCIATION

The Sixteenth Annual Convention of the American Public Health Association meeting held in Montreal, Sept. 15-19, 1931, was attended by fourteen hundred physicians, nurses, and teachers of health from America, Europe, and the Orient. The large attendance and the scientific character of the program easily suggest that the American Public Health Association is one of the outstanding health forces of the world.

The American Public Health Association is now sixty years old, composed of professional workers in the health field. It is the central scientific body in the profession which it represents. It carries on health research and sets standards of health work. It acts as an appraiser of work accomplished. The strength of this organization is the united strength of the public health workers of America. It is an interesting observation that the majority are physicians.

A new and aggressive war on disease is being conducted on a larger scale than ever before in response to public interest. Never before have the resources of science been better applied nor the forces of organization more actively enlisted in public health effort. It is probably true that all this is being carried on to a greater extent in America than anywhere else in the known world.

That the public health field is still unlimited is apparent from the character of the program presented. Two hundred fifty papers were read during the four days of the sessions. Their variety is shown by an enumeration of the scientific sessions,—Vital Statistics, Laboratory, Public Health Engineering, Industrial Hygiene, Food, Drugs and Nutrition, Child Hygiene, Public Education, Public Health Nursing, Epidemiology, and Health Officers. Including those who formally discussed the papers, there were five hundred scientific presentations of public health problems.

The American Association of School Physicians was held separately during the entire four days. There were twenty-nine papers presented. One of them was on "The Early Recognition of Cardiopathic Conditions in Children of School Age," by Robert H. Halsey of New York City. That so prominent an association exists will perhaps be news to many physicians. The attendance at these school meetings was surprisingly large.

One of the most valuable contributions was the address on "Infantile Paralysis," by Dr. Cushing, the Professor of Pediatrics at McGill University Medical School, at one of the sessions of the School Physicians. This was outstanding among all of the addresses.

Since it is the policy of organized medicine today to inform the public as to what medicine is doing for the prevention of disease and the results obtained, it was interesting to hear the address of the editor of the *Montreal Star* on "What is Health News?" He said that two things should be recognized.—"1, that the public as a whole is today favorable to the idea of public health, and 2, that the newspapers today should attempt to show the practical definite steps that the readers must individually take to bring about a general improvement in public health.

To anyone who has given thought to the present-day public character of medicine, to the interest of the public in preventive measures, to the great changes in ten years, to the rapidly growing problems in public health, and the need of increasing the availability of modern scientific medical knowledge,—to anyone who has thought of these things and who has attended the Public Health Sections of the American Medical Association meetings and sessions of the American Public Health Association, there is a very definite impression of the enormous amount of health work that is being done within our own nation and in other nations. Again one sees that this work is actually being done by physicians, and that other organizations are more and more coming to be supplementary. Other organizations are essential for the particular kinds of work that they can do and which medical organizations cannot do. At this annual meeting more that ever it was plain that the technical work in all public health advance depends upon physicians properly supported with means to inform the public on health matters and properly financed on units of area of sufficient size to provide the necessary financial support by general taxation.

The meeting of the American Public Health Association and its affiliated bodies was in many ways one of the most important gatherings of medical men held during this year. It was an example of the opinion today that health problems are international.

While many diseases are rapidly diminishing, it is still necessary to maintain increasing vigilance. New problems are just being attacked. Public health work in such things as venereal disease, cancer, and chronic diseases is just beginning. Greater effort has been made this year to find the cause of disease, and greater effort has been made to solve the problem of the spread of disease. The interesting observation is that in all the activities, physicians are taking the leading parts.

WILLIAM H. ROSS

RADIO BROADCASTS

By the Committee on Health Examination

The Committee on Health Examination of the Medical Society of the State of New York, after two years of research and preparation, is about to conduct, in cooperation with various social, medical, health, and particularly women's, organizations, a fifteen-minute radio broadcast at 11:00 A.M. every Thursday, on the Columbia chain, for fifty-two weeks, during the Women's Hour, which is under the direction of Ida Bailey Allen.

This is the initiation of a carefully worked out program of health education service, by the responsible medical authorities, to the people of New York and neighboring states.

It is designedly concentrated on one subject: Preclinical Medicine (the Health Examination, Foresight, and Management of Life for Health, Happiness and Efficiency; Personal Prevention of Disease, Positive Health). This is the new field of medical service; it needs wise leadership and authoritative guidance. Its service will be great.

This work will seek to bring into service all forces now working in this direction, and the responsibility will be centralized in the official medical organization, where it properly belongs.

This year's program will be concentrated exclusively upon the problems of the woman: her own welfare first; and her responsibilities, children, and family second. The whole life will be covered from babyhood through childhood, preschool, school, high school, adolescence, premarital, marital, motherhood, and grandmother herself. The circumstances and conditions of life occasioned by the school, farm, college, factory, office, home, club, village and city will be considered.

All the several fields of medicine, in its general and special departments, will be covered, in a direct, practical, personal way. Its medical policy will be conservative, constructive, without special doctrine, and strictly impersonal.

Each broadcast will start with a word of greeting and introduction from a prominent and responsible woman representing some organization of women, or some phase of woman's activity. The general hostess for the year is the New York State Federation of Women's Clubs, Mrs. William Dick Sporborg, President, in close association with the Business and Professional Women's Club, and the Parent-Teacher Association.

The physicians giving the medical messages will be those prominent in their respective organizations, or in special fields of medical and health work. They will predominantly be practicing physicians, familiar with the real problems of the woman and the real service of the family physician.

The broadcasting will be done on the Columbia chain; the addresses will be given from Chicago, New York and Washington. From Chicago, the medical leaders of the American Medical Association will be available; from Washington, the medical and other officers in the several departments of the Government, and the women of official Washington and the diplomatic service.

The programs will be concentrated each month on one topic. The first month, September, which marks the reopening of the schools, will be devoted to children, particularly babies and the preschool child; October, to the schoolgirl; November, to the high school girl; December, the month of Christmas, to mothers; January, to the business girl and the business woman; February, to the club-woman and the woman leader in affairs, with particular emphasis on a longer life for great and valuable women; March, to grandmothers; April, to children, in preparation for May 1st, Child Health Day; May, to the girl graduating from high school or college; June, to the fiancée, wife, and mother; July, to camping and the out-of-doors; and August, to husbands.

C. WARD CRAMPTON, *Chairman.*

SIXTH DISTRICT BRANCH

Between eighty and ninety members of the Sixth District Branch of the State Medical Society met at the Iron Kettle Inn near Waverly on the twenty-second of September for the twenty-fifth annual meeting of the Branch. The meeting was called to order by Dr. George M. Cady, president, at 10:50 A.M.

Dr. John A. Conway of Hornell, District State Health Officer, addressed the gathering on "Typhoid Carriers, Surgical and Medical Management." Dr. Conway deems the medical management to be unsatisfactory unless the source be urinary, when the use of hexamethylenamine will, at times, be followed with relief. The surgical approach is better when the source can be determined to be in the biliary tract.

Dr. Oliver W. H. Mitchell, Syracuse, spoke on the topic "The County Health Unit." According to Dr. Mitchell the advantages of the county as a unit far outweigh the disadvantages, and

this conclusion was approved by those who had had experience with this system, and who entered into the discussion that followed.

A nominating committee was appointed by the chair consisting of Drs. H. L. Knapp, Jr., Newark Valley, Tioga Co., H. E. Merriam, Ithaca, Tompkins Co., and G. R. Murphy, Elmira, Chemung Co.

At this juncture the guests of the Branch were introduced and gave their messages: Dr. D. S. Dougherty, State Secretary, Dr. W. D. Johnson, State President, and Dr. John A. Card, Speaker of the House of Delegates.

Adjournment was taken at 12:30 P.M. until 2:40 for luncheon.

Upon reassembling the nominating committee reported the following names as candidates for officers of the Branch: Dr. S. B. Blakely, Binghamton, for president, Dr. John E. Wattenberg, Cortland, for first vice-president, Dr. L. P. Larkin, Ithaca, for second vice-president, Dr. H. B. Marvin, Binghamton, for secretary, and Dr. W. A. Moulton, Candor, for treasurer. These candidates were elected unanimously.

Dr. Arthur C. Morgan of Philadelphia gave an excellent paper on "The Treatment of Cardiac Tragedies," which evoked considerable discussion.

The meeting was closed by Dr. G. S. Carpenter, of Waverly, who gave the history and operation of the Tioga County Hospital, and issued invitations to all to make an inspection of that institution at the close of the session. This invitation was accepted by a large number of the doctors. H. B. MARVIN, *Secretary.*

DUTCHESS-PUTNAM SOCIETY

A regular meeting of the Dutchess-Putnam Medical Society was held September 16, 1931 at the Nelson House, Poughkeepsie, N. Y. The meeting was called to order by the Vice-President, Dr. W. A. Krieger at 9:00 P. M.

Committees were appointed to adopt suitable resolutions to be sent to the families of the late members, Doctors Charles L. Fletcher and S. I. Jacobus.

The following resolution was introduced and adopted:

WHEREAS, it has been brought to the attention of the Dutchess-Putnam Medical Society, that there is at the present time, in the State Legislature, a bill to authorize the City of Poughkeepsie to issue bonds to the extent of One Hundred Thousand Dollars, ($100,000.00), to cover the cost of a sewer leading from the Bowne Memorial Hospital; and

WHEREAS, the passage of such a bill would not only relieve some of the unemployment situation, which is existing at the present time, but provide an adequate means of sewage disposal for that institution, which is important from the standpoint of health and sanitation;

THEREFORE, BE IT RESOLVED, that the Dutchess-Putnam Medical Society heartily endorse the project, and petition the State Legislature now assembled, and the Governor of the State, to use their efforts towards the immediate passage of such bill; and

BE IT FURTHER RESOLVED, that the Legislative Committee of the Dutchess-Putnam Medical Society, be authorized to transmit such resolution to the proper authorities.

Doctor John A. Card introduced the following resolution which was adopted after discussion:

The Dutchess-Putnam Medical Society passed a resolution commending the action of the various Boards of Health, in the Counties, in keeping the schools closed and requesting the closing of the Sunday Schools during the prevalence of the outbreak of poliomyelitis; and it further recommends that the Boards of Health be requested to forbid the attendance of children under 18 years of age from the moving picture houses.

The Secretary was appointed reporter to the State Society.

Dr. George T. Pack, Memorial Hospital, New York City, gave a paper on "The Management of Mammary, Uterine, and Oral Cancers," illustrated with lantern slides.

The meeting adjourned at 11:00 P. M. for refreshments.

Present: Drs. Sadlier, Appel, Baldwin, Stoller, Andrews, Thomson, Conger, Davison, Bulkeley, Harold Crispell, Burns, C. E. Lane, Stibbs, Peckham, Voorhees, Gosse, Harrington, Simon, Taber, Sobel, Leonidoff, Smith, Christensen, Dingman, Card, Krieger, Carpenter, Toomey, Rogers, Merritt, guest (Vassar College),— 32 in all. H. P. CARPENTER, M.D., *Secretary*

BRONX COUNTY

A Special Meeting of the Bronx County Medical Society, held at Elsmere Hall, on September 16, 1931, was called to order at 9 P.M., the President, Dr. Irving Smiley, in the Chair.

The President announced that the meeting was called for the purpose of conducting a Symposium on Immediate and After-Care of Poliomyelitis.

The Scientific Program then proceeded as follows:

Immediate and After-Care of Poliomyelitis:

A. Medical Aspects, James P. Leake

B. Neurological Aspects, Joshua H. Leiner

C. Orthopedic Aspects, Samuel W. Boorstein

The subject of the evening was then further discussed by Drs. William L. Rost and Samuel A. Jahss, following which the discussion was closed by Drs. Leake, Leiner and Boorstein.

It was moved that the Society extend a vote of thanks to the readers of the papers for their splendid presentation of the subject. This motion was unanimously carried, and the President accordingly expressed the appreciation of the Society. I. J. LANDSMAN, *Secretary.*

ROCKLAND COUNTY

The September meeting of the Medical Society of the County of Rockland was held at the State Institution, Letchworth Village, Thiells, New York, on the afternoon of Wednesday, September 23rd, 1931, with thirty-eight members present out of the total membership of fifty-two. The meeting was called to order with the President, Dr. Leo G. Weishaar in the chair. Dr. Maximilian Moses was elected to membership.

The meeting was first addressed by Dr. James Vander Veer, past president of the State Medical Society, of Albany, New York. Dr. Vander Veer appeared in behalf of the State Society as chairman of the Venereal Disease Committee. The doctor stressed many features which he considered neglected in the diagnosis and treatment of syphilis. Among them was early diagnosis. He recommended the greater use of the dark field study for the spirochetes, and also emphasized the necessity of further Wassermann Tests since the first Wassermann is frequently negative in very early lesions. Dr. Vander Veer impressed the members of their obligation in carrying out the treatment of syphilitics, and pointed out that a great number of chronic invalids who exist in our institutions as public charges results from inadequate antisyphilitic treatment during the early stage. (See this Journal, June 1, 1931, page 712.)

Dr. Albert Pfeiffer, Director of the Division of Social Hygiene, appeared before the members as a representative of the State Department of Health, and told the physicians what the State had to offer. Drugs for the treatment of syphilis would be furnished to the physicians free of charge for indigent patients. He explained that so many patients who discontinue their treatment (which should be prolonged) on account of financial reasons later become public charges in our institutions as a result of this disease. He stated that there are many thousands of people today in our state hospitals as a result of untreated syphilis. The new Public Welfare Law authorizes county boards of supervisors to establish venereal disease clinics. The state will match the county funds dollar for dollar. Dr. Pfeiffer is anxious that the medical society and county officials establish such clinics in Rockland County.

Dr. George W. Henry of the Bloomingdale Hospital at White Plains was the concluding speaker. His subject was "Practical Applications of Psychiatry to General Medical Practice." His discussion was both interesting and illuminating. Dr. Henry cited many actual cases where the patient had undergone several operations or long periods of hospitalization in different institutions for treatment of organic diseases where the condition was purely functional. This subject aroused considerable interest.

After the meeting adjourned, the members were the luncheon guests of Dr. Charles S. Little, Superintendent of the Institution, who proved himself to be the usual delightful host.

WILLIAM J. RYAN, *Secretary.*

ALBANY COUNTY

The September meeting of the Medical Society of the County of Albany was held at the Albany Hospital on Wednesday evening, September 23, 1931.

Following the regular order of business, Dr. William Feltman, Albany Medical College, 1930, was elected to membership. The chair announced that Dr. Huntington Williams, Secretary of the New York State Department of Health and Chairman of our Local Committee on Public Health would leave September 28th to assume charge of the Department of Health for the city of Baltimore, Maryland.

We rejoice in Dr. Williams' call to a larger field but regret to lose him from our membership.

The Scientific Program was presented by members of the Staff of the Albany Hospital, and consisted of the following interesting papers:

Peritoneal Carcinomatosis, Dr. John A. Sampson.

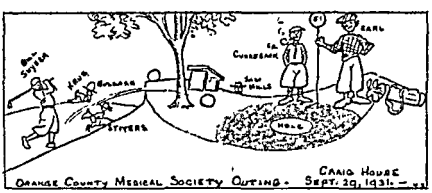
The Present Local Epidemic of Poliomyelitis, Dr. Henry L. K. Shaw.

Ten Years of Obstetrics, Dr. Thomas O. Gamble.

This meeting was one of a series that have been held at the various hospitals of the city during the year.

The Society will celebrate its 125th anniversary with a dinner at the De Witt Clinton Hotel on Wednesday evening, October 28, 1931, at 8:00 P.M. The principal speaker will be Dr. George W. Crile, of Cleveland, Ohio.

The Hon. Franklin D. Roosevelt is expected to be present. It is planned to make this one of the outstanding events in the Society's history.



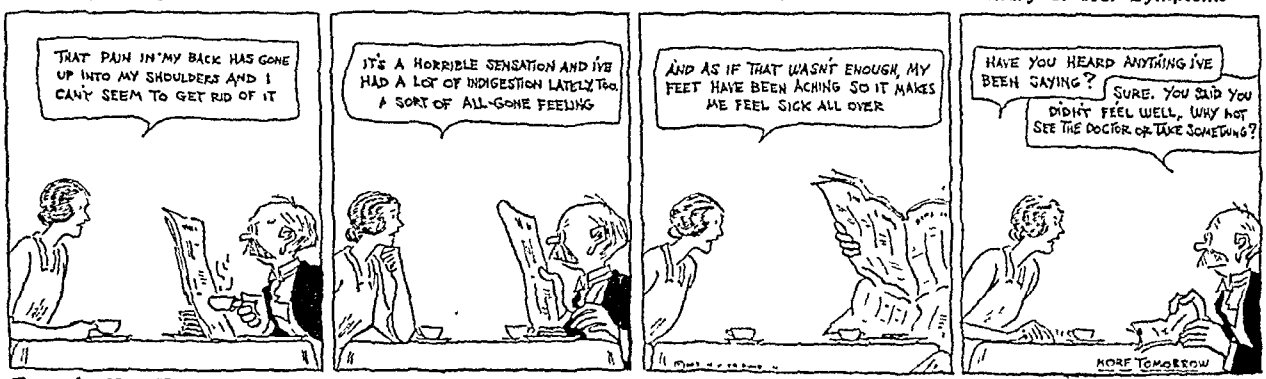
HOMER L. NELMS, *Secretary.*

ORANGE COUNTY.

A joint meeting of the Orange County Medical Society and the Newburgh Bay Medical Society was held on September 29 in the Craig House, Beacon, with forty members present.

Craig House is not a hotel, but a sanatorium at which psychopathic and neurological cases are given instructions in handicraft, including golf. Dr. C. J. Slocum, the Medical Director, conducted the visiting doctors through the institution and explained the therapeutic measures in use there.

The meeting was largely social and recreational, and the program included golf and a clambake.



Heading of the Mimeographed Notice of the Meeting

H. J. SHELLEY, *Secretary.*

THE DAILY PRESS

Mr. and Mrs.— *Vi Gives Joe a Summary of Her Symptoms*

From the *New York Herald Tribune*, June 11, 1931.

TREES WITH FEELINGS

Who was it that said a tree groans at every stroke of the woodsman's ax? Whether or not trees can feel and think as do human beings, there is no doubt that to human eyes they may appear to rejoice or suffer—at least so they seem to James J. Montague in the following verses which were published in the *New York Herald Tribune* of September 21:

"The birches and the maple trees,
When winter is at hand,
Fling off their clothing to the breeze
And bleak and bare they stand.
The elm without his yellow cloak
Will presently appear,
And stripped and cold will stand the oak
Until the spring is here.

"Where once the willows formed a screen
That held the gales at bay,
The hills and valleys may be seen
For miles and miles away.
And high above the forest floor,
Majestic in its grief,
The stately mottled sycamore
Has cast its last lone leaf.

"But though in bitter undertones
The pines and firs may sigh,
And though the laden hemlock groans
When every gust goes by,
They still are clothed and snug and warm
When summer days depart,
And never any bitter storm
Can chill them to the heart.

"And when the air is keen and chill,
And hurrying snowflakes sting,
And one walks out beyond the hill
To seek for signs of spring,
They always seem in peace and ease,
Well muffled to their throats,
And shielded from the biting breeze
In winter overcoats."

FAITH HEALING

The New York *Herald Tribune* of September 21, contains an account of the report of a commission on faith healing in the General Assembly of the Protestant Episcopal Church at Denver. The report says:

"A joint commission of the Protestant Episcopal Church, after nine years' study of the problem of Christian healing, recommended to the general convention of the church today that those who practice such healing in the church operate in cooperation with the medical profession.

"The commission pointed out that, while the church must teach that spiritual healing is an integral part of the Gospel of Christ and part of the pastoral office, it must not teach or use any methods tending to lead people to believe it is the only, or even the primary, element of that gospel.

"No sober minded man," the report recites, "can dispute what materia medica has done for humanity to alleviate the suffering caused by disease and accidents and the practical eradication of certain diseases.

"We may believe that this progress in medical science has been due to certain illumination of the spirit of God. The church will not fail to give due credit to the medical profession for its noble work for poor suffering humanity."

"The primary stress of a constructive move-

ment, the commission states, must be placed on "health" and not healing. By stressing health, the Church must have an effective message to the sick, as it now has for the sinful.

"Many today would stress what is called 'the sacrament of unction.' To them it has not only the psychological but also sacramental value," the report states. "It is clearly Scriptural and has behind it the authority of apostolic times. We rejoice that there is a form of service for its administration. But no one, however high the value he placed on it, would question that it is only a means to a spiritual end.

"A sane constructive health movement can not be based upon the use of consecrated oil; that is not its primary truth. The same may be said of 'a gift of healing,' so much disputed and about which we know practically nothing."

PSYCHOLOGICAL TESTS FOR GUILT

Psychologists are giving much attention to methods of detecting criminals: and they frequently stage demonstrations before classes of college students. The New York *Herald Tribune* of September 25, comments editorially on the failure of a test in Columbia University, and point out the reason for the failure. The editorial says:

"Three different types of method cover the majority of these psychological machines, if not all of them. One is to test the time taken by suspected persons in replying to questions or in supplying words associated with those presented by the examiner. The assumption is that the person who has guilty knowledge of which he is reminded will take longer in his replies or will make these replies in some other abnormal way. A second method tests certain bodily functions, like the rate of the heartbeat or the number of respirations each second. Here it is assumed that guilty knowledge will cause the heartbeat or the respiration to quicken when this knowledge is brought to mind by questions or suggestions. Third is the method of the psychogalvanic reflex, a nervous stimulus which lowers greatly the electrical resistance of the skin and which is believed to be elicited by thoughts or secrets which the individual tries to conceal.

"In reality, all three of these mental reactions are evoked directly by emotions. Laughter or fear will lower the skin resistance even more than trying to lie. A joke or a sweetheart will make the heart beat faster and will quicken the rise and fall of the breathing muscles. The theory of the lie detectors is that any attempt to conceal something arouses emotions and that these emotions produce the reactions concerned. Usually this is true, but not always. Probably Dr. Lecky's two subjects already were as excited as possible by being asked to take part before their classmates in such a test. Perhaps one or both of them failed to be excited at all because of the realization that the whole drama, after all, was nothing but make-believe. Real criminals, it has been found, often respond poorly to these tests because they lack the quick emotional responses of ordinary folk.

COSMIC DUST

The *Herald Tribune* of September 13, comments editorially on a paper presented before the American Astronomical Society by Dr S. F. Carpenter of the University of Arizona. The Professor discussed the data in evidence of the existence of so-called cosmic dust, and says:

"The significance of these data for our own cosmic neighborhood is in the fact that this star-dimming dust cloud is not everywhere. It seems to be localized on the contrary, in a broad belt of the heavens approximately parallel to the Milky Way."

Dr. Carpenter likens the cosmic dust to the smoke thrown off by a pinwheel on fire, and says:

"On the fringe of an ordinary pinwheel is first a ring of sparks and outside this another ring of smoke and darkened dust. In our celestial pinwheel the fringe of sparks is the star ring of the Milky Way. Dr. Carpenter's facts show that there exists also the expected outer fringe of dust and smoke. In one or two spots in the sky telescopes show spiral nebulæ which we chance to see edge on, like viewing a fireworks pinwheel from one side. Sure enough, photographs show dark central lines bisecting the lengths of these sidewise presentments and indicating, it is probable, dust around the star cloud's edge. If we could get far enough away from earth for a similar outside view of our own home Dr. Carpenter's data indicate that it would look the same."

OUR NEIGHBORS

LEGISLATIVE COMMITTEE IN IOWA

The September number of the Journal of the Iowa State Medical Society contains an excellent editorial on the problems connected with state medicine and on the manner in which the Iowa State Society is meeting them. The article says:

"It has been well said that the paramount problem now confronting the medical profession of America is whether medicine is to be practiced and controlled by properly qualified physicians or by untrained usurpers (untrained laymen). For the past thirty years these problems have become increasingly acute in Iowa, and the members of this society are confronted with four decisive questions. It should be noted clearly that each of these four problems has a direct bearing on the larger issue 'state medicine.' They are:

"1. Should unqualified persons be permitted to practice medicine in Iowa?

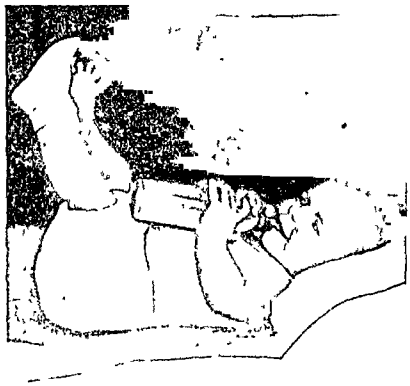
"2. Should corporations control the conditions of medical practice?

"3. Shall public health activities be guided by laymen or by the medical profession?

"4. Is the method of operating the University Hospitals detrimental to private practice?

"The Legislative Committee of the Iowa State Medical Society has been instrumental in and has succeeded in securing favorable legislative answers to each of these four vital questions."

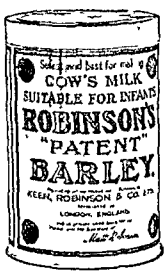
The answer of the State Society to the first question is as follows:



"A few years ago the statement was made that 'due to a weak medical practice act which is almost impossible of enforcement, Iowa is not only the dumping ground for quackery, but it is the one state in the Union where osteopaths and chiropractors are practicing medicine almost without restraint.' The activities of the Committee on Public Policy and Legislation, backed by the hearty support of the members of the profession and the various county medical societies have in the past two or three sessions of the General Assembly of Iowa almost entirely reversed this situation.

"In the entire history of law enforcement in the state of Iowa prior to July, 1929, all legal proceedings against violators of the medical practice act were less than a dozen in number and there had been but two or three convictions. In the last two years nearly one hundred individuals have been restrained from the illegal practice of medicine. Three things are responsible for this remarkable change: (1) improvement in the medical and other practice acts in the Forty-fourth General Assembly; (2) the creation of an inspection division in the Department of Health; and (3) the assignment of a member of the Attorney General's office to specialize in handling all cases concerning the practice acts. Your Committee on Public Policy and Legislation sponsored and cooperated in the enactment of certain laws which make it possible to prevent the practice of medicine by untrained persons. Your committee also worked for the measures which have placed in the Department of Health two full time inspectors whose sole duty is to secure evidence of violation of the practice act. Finally, through the just, efficient and fearless administration of the law and prosecution of violators through the Attorney General's office, there has been brought to justice an average of one case a week for the past two years. A prominent Iowan recently remarked that a thorough understanding of the necessities and standards of medical practice and the intricacies of the code could be achieved only by intensive attention to their legal aspects. The remarkable results accomplished are thus due not only to improvements in the law and the securing of the inspectors, but also to cooperation and specialization in the legal phases of this great program of protecting the people of Iowa from unscrupulous practitioners.

"When the Committee on Public Policy and Legislation recently tackled the problem of securing for Iowa physicians (as well as the hospitals) fair treatment at the hands of the corporations and other employers, under the Workmen's Compensation Act, the Iowa statutes unreasonably restricted the total amounts which had to be paid for the care of injured workmen. The maximum amount which an employer or the insurance company for him could be required to pay for all hospital, medical and surgical and other professional services, was originally $100. As a result of the very determined and successful effort on the part of the State Society, this limit has now been raised to $300.



"While the financial aspect of this problem is an important consideration, yet it is in reality the minor one. The vital question here is whether or not the physician, his relation to the patient, and his fees, are to be arbitrarily and often unreasonably controlled by the state and by corporations. Here is very clearly an issue involving questions of 'state medicine' and the issue cannot be considered as settled until the physician is fully recognized as a major part in all problems affecting the health and medical treatment of workmen. In all

For the Normal Infant *or in cases of*

Milk or Sugar Intolerance

Sealed in metal containers, ROBINSON'S "PATENT" BARLEY *reaches your patient clean and pure The ideal diluent of cow's milk, and an invaluable remedy for infant intestinal disorders*

Standard since 1823

VALUABLE as *Robinson's "Patent" Barley is in* the diet of the normal infant, it has proved its added value in the cases of infants who do not thrive on the usual diets. Such cases may be due to intolerance of milk fat, milk protein, or sugar.

IF DUE to *milk fat* intolerance, the fat content of the feeding is reduced and the deficiency made up by the addition of carbohydrate. While soluble sugar may be used, the amount required may be too much for the infant, since its rapid rate of absorption often causes sugar to ferment in the intestine

Carbohydrate, in the form of Robinson's "Patent" Barley, however, is being used with great success. It is absorbed more slowly, since it has to be converted through the stages of dextrin and maltose to dextrose before it is absorbed

WHERE INTOLERANCE is due to non-digestion of *milk protein* caused by the formation of casein clots in the stomach, the remedy is to modify cow's milk with Robinson's "Patent" Barley It causes cow's milk to curdle in smaller, more digestible clots—like human milk—rather than in the larger clots typical of cow's milk.

Sugar intolerance, vomiting, and other infantile digestive disturbances have also been found responsive to correctly prescribed diets modified by Robinson's "Patent" Barley—a product prescribed by physicians for over a century.

Robinson's *"Patent"* Barley

Collosol MANGANESE

CROOKES

MANGANESE is one of the inorganic elements recommended for many years for blood regeneration and for the treatment of coccogenic affections, particularly Furunculosis, Boils, Acne, etc.

It is safe to inject and is almost totally free from the pain and discomfort attendant on the injection of solutions of manganese salts.

COLLOSOL MANGANESE 1-400 is extremely stable and does not precipitate on addition to the blood plasma.

COLLOSOL MANGANESE is most successfully used intramuscularly, although some observers report favorable results from hypodermic injection. It has also a growing acceptance for oral use.

Ampoules for intramuscular injection.

Vials for oral administration.

CROOKES LABORATORIES, Inc.

(*Continued from page* 1296)

fairness it should be stated that there is now every evidence of a spirit of conciliation and cooperation on the part of most of the more important corporations and insurance companies in this state, and it is possible that further adjustments may be secured by cooperation and mutual agreement."

In regard to the third question, that regarding lay control of public health activities, the editorial says:

"Laymen are not endeavoring to control medical practice in Iowa, thanks to the cooperative spirit of the various lay organizations, the leadership of the State Society in working out administrative problems, and the county health unit law passed in the Forty-third General Assembly. This is a permissive law which allows any county board of supervisors which so desires to unify all local health activities under the county board of health.

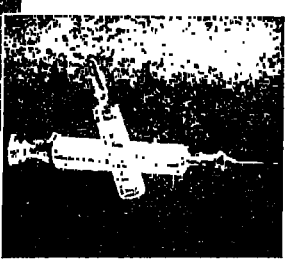
"The important detail in this plan is that three of the eleven members of the county board of health must be members of the local medical society. This provision insures cooperation between the members of the profession and the county health program and makes certain that the program itself will be based upon sound health and medical principles. This plan has been nationally recognized as sound and effective from the viewpoint of scientific medicine."

The answer to the fourth question dealt with local conditions, especially the manner of conducting state hospitals. A special committee to study this question will report to a special meeting of the House of Delegates to be held sometime before the Annual session. The article closes:

"The physicians of Iowa more than ever before are receiving fairer treatment and better recognition and cooperation in their efforts to protect the health and medical interests of the citizens of this commonwealth. Unity, cooperation and an unselfish interest in public welfare have produced these results. Continued unity and support can accomplish still more and every member of the Iowa State Medical Society should keep himself fully informed of the legislative and political program."

OFFICE OF THE INDIANA MEDICAL ASSOCIATION

The September number of the *Journal of the* Indiana State Medical Association devotes twenty pages to the annual reports of the officers and committees to the House of Delegates which meets on September 23 in Indianapolis. The first report is that of the Executive Secretary, Dr. Thomas A. Hendricks, who describes the work done in the central office in an interesting way, as follows:



" 'What do they do at the headquarters office?'

A New Bismuth Solution for the treatment of Syphilis

"Complete and Self-sufficient in itself"

AFTER over a year of laboratory research and clinical observation, The Drug Products Co., Inc., presents to the medical profession a bismuth solution in true colloidal state for intramuscular injection in syphilis.

Quickly absorbed and slowly eliminated, Bi-Na-Gluconate exerts maximum therapeutic effect without toxic or other detrimental reaction.

Being both water and tissue soluble, injections are painless and easy. Absorption is certain and complete. X-Ray shows complete absorption in from 48 to 72 hours. It produces no local induration or systemic reactions.

is the question often asked by members of the profession not directly in touch with Association activities. The best way to get an idea of the workings and accomplishments of the State Association is through reading the annual reports of the officers and committees that follow. This will give you some idea of the scope of work carried on by the State Association and will give you a conception of some of the questions that will come up for consideration before the House of Delegates and the Council at the coming session.

"A short outline of some of the duties of the headquarters office follows:

"First, we have an active, full-time staff of three persons on the job every working day at headquarters, and through this office the various activities of the county societies, the legislative committees and the American Medical Association program as it affects Indiana are correlated and executed. The work of this office is growing tremendously. In fact, so increased has the routine work alone become that we are faced with the necessity of employing a part-time girl to help out when the dues start to come in the first of the year. By routine work we mean the filing of letters, the constant correcting of membership records of some 4,000 physicians, the making of monthly reports of the American Medical Association, the collection of membership dues, the maintenance of medical defense records, the keeping of the treasurer's books, and the sorting and tabulation of the ever-increasing volume of work done by the Publicity Bureau. So small has the office become that this extra girl probably will have to work on Saturday afternoons when the office ordinarily is closed, at night, etc.

"1. At the headquarters office all of the administrative details of the Association, working through the State Executive Committee and under the control of the Council, are handled. Visits are made to the weak societies, they are bolstered up and all societies are helped to maintain a high standard of activity—

"(a) By talks of the society officers before county and district societies.

"(b) By monthly bulletins to secretaries of county societies.

"(c) By keeping a complete Kardex record of every physician, not only of the physicians who are members of the State Association, but every physician in the state. These records are up to date. Reports of these records are sent monthly to the American Medical Association. A complete tabulation is kept as to physicians in good standing, physicians who are blacklisted for ethical reasons and a

(*Continued on page 1301—Adv. xvii*)

(*Continued from page 1300—Adv. xvi*)

brief history concerning each individual member of the Association, the time he was licensed to practice medicine in the state, the school he attended, his date of graduation and his present location.

"2. Answering of many ethical questions through the Bureau of Publicity and Executive Committee.

"3. Maintaining an up-to-date file of possible locations that are available for physicians. This is done in cooperation with the salesmen of the various large pharmaceutical houses of Indiana. Splendid results have been obtained from this service.

"4. Supplying of material for medical and lay talks. Many requests are received for such material.

"5. Making out special membership lists for secretaries of district societies.

"6. The headquarters office keeps all records of medical defense cases. The Indiana State Medical Association has an unusually successful medical defense program for its members. Seventy-five cents of each member's dues go to medical defense. This entails a great deal of clerical and stenographic work.

"7. All detailed work of the treasurer's office has been done from this office since the first of December, 1925. This concentrates all administration duties of the State Society in one office, the collection and recording of dues, issuing of membership cards, etc. The State Medical Journal, one of the best in the country, is edited and published by Dr. A. E. Bulson, at Fort Wayne.

"8. A report upon every legislator who comes to Indianapolis is on file at this office. Records of every vote of every legislator on medical questions for the past six years are maintained. Through the State Legislative Committee, which meets in the headquarters office daily, if necessary, during the legislative session, the profession is kept in constant touch with the doings of the Legislature. This touch is maintained through the various county legislative committees. (Each county society has its own legislative committee which cooperates with the state committee.)

"9. The headquarters office is also the headquarters of the Bureau of Publicity of the Indiana State Medical Association. This Bureau meets once a week and does an infinite amount of work. It sends out weekly an article on scientific medicine to 250 papers and 800 members of parent-teacher associations throughout the state. It maintains a speaking bureau and provides medical speakers for lay meetings. It supplies also essayists for county medical society meetings. If a county society wants a speaker on any subject, the county secretary writes to the head-

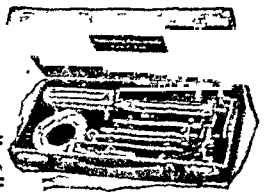
ELECTRICALLY LIGHTED SURGICAL INSTRUMENTS



"E. S. I. Co."

The mark that stands for quality and service also represents a complete line of electrically lighted instruments for specialists in practically every field.

The tenth edition of the E. S. I. Co.'s catalog is interesting because it not only outlines the wide scope of the line, but describes the most recent developments in this important field.

quarters office and the matter is presented to the Publicity Bureau. The Bureau is a real bureau of information and answers all questions that arise. The various newspapers of the state and the various press associations have become accustomed to calling the headquarters office in regard to questions of medical news. Thus, authentic information upon medical occurrences comes from the headquarters office. The headquarters office cooperates with the Better Business Bureau in making reports and gaining information upon quacks.

"10. The headquarters office makes all arrangements for the convention, meeting with local committees to insure proper accommodations, proper meeting places, proper entertainment, etc. (This work starts for each year right after annual ing of year before.)

"11. One of the big duties of the headq ive office is the handling of the commercial e ia- at the annual meeting. This alone takes a ed mous amount of time and correspondence, ng is well worth while as it gives the State A u- tion a good income. The headquarters o th responsible for laying out the floor plan, s to out the announcements, getting in the co st and collecting the money for the commerc ng hibit at each convention.

"12. General Duties. Besides this, the quarters office acts, as nearly as possible, a resentative for each individual physici Indiana who is a member of the state s Special effort is made to give complete inf tion and wholehearted help to individual cians who write in on any matter. We lo and check up on cases that individual physi have before the Industrial Board, physi throughout the state can call upon us for info tion they may desire in getting material essays, or obtaining information or anything has to do with the medical profession. This is growing each month. The headquarters acts as representative for the medical profes cooperating with the Indiana University S of Medicine, with the Indiana Council of S Agencies, and maintains close touch and coo tion with the State Board of Medical Registra and Examination.

"In short, the headquarters office will atte to handle any professional or personal prob of a medical nature of any of its members w these questions are submitted to it. Questi will be answered relating to the practice of m cine and the interpretation of any state or fed law, state compensation law, state license l narcotic laws, health laws. It will see that qu tions are answered relative to licensure and ciprocity. It will give advice upon any collect matter. The headquarters office desires to be the greatest benefit possible."

PERSONALS IN NEBRASKA JOURNAL

"Some state medical journals print personal notices of physicians. The Nebraska State Medical Journal of September contains the following note on its department of Human Interest Tales:

"For the Human Interest Tales in *The Nebraska State Medical Journal* we are almost wholly dependent on press clipping service. Lately, because of a shortage of material, it has occurred to us to make a comparison of items with the first 8 months of last year, with the following result:

	1930		1931
talks.	25	January	20
materi	19	February	30

not produce the 'Tales'. The clipping bureau suggests in response to our complaint that it is just possible that the doctors are a little short of change for vacations and postgraduate courses and marriages this year.

"The department in the September Journal fills less than a column and consists of short items, of which the following are examples:

"Dr. G. W. Briggs, formerly of Decatur, has located at Walthill.

"Dr. L. D. McGuire, Omaha, submitted to a herniotomy, last month.

"Dr. and Mrs. C. W. M. Poynter, Omaha, motored in New England in August.

"Dr. Adeline Ashton, Chicago physician of note, visited relatives in Omaha, in July.

"Dr. R. B. Adams, Lincoln, secretary-treasurer of the Nebraska State Medical Association, spent a six weeks' vacation in the Canadian woods.

"Dr. E. I. Conner, medical missionary of Sierra Leone, Africa, is in the state on leave of absence and is lecturing under the auspices of the United Brethren church."

THERAPEUTIC ALMANAC

SEPTEMBER OCTOBER

Months of change and readjustment in diet, clothing, living habits. Coughs, colds, tonsilitis will again gain the upper hand. Acidosis is generally a predisposing, frequently an accompanying, and always an aggravating factor.

Rx ALKA-ZANE

A teaspoonful in a glass of water, taken after effervescence has subsided, two or three times daily, will efficiently prevent acidosis.

Note—Alka-Zane combines the carbonates, phosphates and citrates of sodium, potassium, calcium and magnesium. No sulphates, tartrates or lactates; no sodium chloride.

ALKA-ZANE *for Acidosis*

GROUP COUNTY SOCIETIES IN WYOMING

The Wyoming section of *Colorado Medicine* for September discusses group county societies as follows:

"The success of the Northwestern Wyoming Medical Society, since its organization several years ago, points the way to the possibilities of three other similar organizations in Wyoming. The Counties of Park, Big Horn, and Washaki are located in the Big Horn Basin in northwestern Wyoming. Any one of these large but sparsely settled counties could not support a successful county medical society, but by uniting these three counties into one organization a strong society was formed and has successfully met the needs of the physicians in this area.

"In the northwestern part of Wyoming are Crook, Weston and Campbell Counties. In these three counties there are no large cities and in most of the counties only three or four physicians. However, by uniting these counties into a medical society much could be accomplished.

"Likewise in the southeastern part of Wyoming the Counties of Goshen, Platte, Niobrara, and Converse a strong society could be created.

"In the extreme southwestern part of Wyoming, Uinta, Lincoln, and Teton Counties could form the Southwestern Wyoming Medical Society.

"If we cannot support a live County Medical Society in every county let these counties unite their numbers and make a strong society. It is true that under our present State Medical Society Constitution a physician can join some adjoining county society, or he may in the absence of a county society in the county in which he lives, join the State Society. Yet by so doing he loses the companionship of a local society and has no vote in the House of Delegates which is the business body of the State Medical Society, and in turn the State Society loses the help of these unorganized physicians.

"It is true they can be members of the Wyoming State Medical Society and as such become members of the great American Medical Association, but by the organization of these thinly settled parts of Wyoming into strong societies composed of several counties much can be accomplished that is not now being done for the medical men of Wyoming.

"This year's program ought to include such organizations. We will all then be members of a stronger and better state organization."

Have you ever used *Colloidal Kaolin?*

Colloidal Kaolin joins hands with sodium, magnesium, calcium and bismuth in Cal-Bis-Ma for quick and lasting neutralization in gastric hyperacidity and for the protection of the mucous membrane of the stomach and intestinal tract. Colloidal Kaolin not only takes up gases, but also "adsorbs bacterial poisons in the intestine, and is a potent and efficient agent in rendering these poisons innocuous." It prevents intestinal fermentation to such extent that the stools are almost odorless. That is why the protective action of Cal-Bis-Ma does not end in the stomach but continues on throughout the intestinal tract. Cal-Bis-Ma contains no digestive ferments because gastric ferments are inactive in alkalies.

In Gastric Hyperacidity

CAL-BIS-MA

Its up to date composition explains the efficiency of Cal-Bis-Ma, a clinical test will demonstrate its effectiveness. Send for a trial supply.

WILLIAM R. WARNER & COMPANY, Inc., 113 West 18th Street, New York City

MEDICAL SERVICE TO VETERANS IN PENNSYLVANIA

No physician begrudges free medical treatment given to a veteran for conditions arising from his war service; but there is condemnation of the gift of medical service when the defect has no relation to army service, or the veteran is abundantly able to obtain the service for himself A protest against indiscriminate medical service to ex-soldiers of the World War was voiced by Dr. Walter F. Donaldson, Secretary of the Medical Society of the State of Pennsylvania, speaking before the Tri-State Conference as recorded in the August issue of the *Pennsylvania Medical Journal*. Dr. Donaldson sketched two soldier comrades, one a successful business man and the other a doctor. The business man had partly arranged that the doctor should operate on him for an epididymitis contracted ten years after the war, but a friend switched him to take free treatment in a Veterans' Hospital. The author says:

"After a stay in the hospital three weeks longer than necessary, or possibly had Jones been paying for it (it is difficult to find enough patients to fill the beds in many of the government hospitals), Jones returned to his home town, where for a long time he 'groused' about the quality of the free service he received from a bureau-controlled government hospital.

"In the meantime, Dr. Smith having aroused the interest of his fellow Federal income-taxpayers on the board of directors of the local hospital, as well as in the county medical society, is, or should be, endeavoring to convince his congressmen and the senators from his state that the Federal government must respect certain fundamental principles of 'states' rights,' and abandon its policy of providing free medical and hospital care, and financial relief for war veterans, except for impairments which can be reasonably related to war service, or the veteran who is unable to pay for treatment. Dr. Smith contends that since physicians represent the first group of citizens whose economic welfare is seriously threatened by this form of paternalism, and since they compose one of the few remaining individualistic professions, it is the duty of physicians to become politically conscious and to take the lead in fighting for recognition of 'states' rights' and for discontinuance of Federal interference.

"Surely, those who pay taxes to the United States Government will not supinely continue to approve free medical, surgical, and hospital treatment of the disabilities of 4,500,000 veterans which originate as ordinary incidents of everyday life twelve or more years after the World War ended. Congressmen and senators who support such legislation must be rebuked at the polls, and the great majority of the veterans retaining their patriotic principles must repudiate the noisy minority who continue their raids on the public treasury.

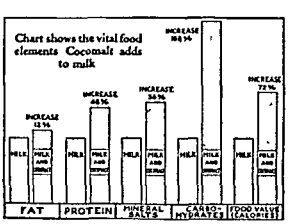
. . . whenever milk is an important part of the diet

Cocomalt not only renders it more palatable but increases its food value over 70%

COCOMALT is a delicious, high-caloric food—ideal for convalescents, expectant and nursing mothers and undernourished children.



Not only does Cocomalt make milk a tempting chocolate flavor drink; *it actually increases its food value 70%*—adding 46% more protein, 56% more mineral salts (Lime and Phosphorus), 188% more carbohydrates.

Because Cocomalt contains Vitamin D in sufficient quantity to make a definite contribution to the anti-rachitic potency of the child's diet, it is especially beneficial to growing youngsters.

Cocomalt is available at grocery and drug stores in ½ lb., 1 lb. and 5 lb. hospital can.

Rich Vitamin Content

at a reasonable cost

ISN'T THAT WHAT YOU WANT FOR YOUR PATIENTS IN A COD LIVER OIL?

Puretest Cod Liver Oil meets the highest standards of vitamin potency

Puretest Cod Liver Oil has a Vitamin A content of not less than 50,000 U.S.P. units in each 100 grams.

Puretest Cod Liver Oil has a Vitamin D content of not less than 13,333 Oslo units in each 100 grams.

When you have a patient who needs the building-up properties of Vitamins A and D, you probably suggest cod liver oil as the richest combined source of these two vitamins.

Of course you realize that all cod liver oils are not equally rich in vitamin content. It depends on where and when the fish are caught, how the livers are prepared and how the oil is protected from deterioration.

If you would specify a cod liver oil which is very rich in Vitamins A and D, which is always stable and uniform in quality, specify Puretest.

Puretest Cod Liver Oil comes from the chosen waters of Lofoten, Norway, North of the Arctic Circle. The cod are caught during the early part of the year when the livers are richest in Vitamins.

In every operation of preparing and shipping, utmost care is taken to insure pure quality of the oil and to protect and preserve the rich vitamin content. With each shipment comes a certified biological analysis.

But you ask one thing more of the cod liver oil you specify. A reasonable price. For the average patient does not feel like paying a high price for such a well-known, long-used product. And he does not need to.

For Purest Cod Liver Oil provides as high a vitamin potency as you can wish at a price moderate enough to please your patients. All Rexall and Liggett Drug Stores have Puretest Cod Liver Oil. We will gladly send you samples for your tests. Write to the Medicine and Hospital Department.

(*Continued from page* 1305—*Adv. xxi*)

"Dr. Smith, while agreeing that our Federal government should show every possible reasonable consideration to our war veterans, also emphasizes the fact that a larger proportion of physicians entered government service in 1917 and 1918 than from any other professional group. When the proposed 47 or more veterans' hospitals, each sustaining more salaried employees than patients, have been completed and occupied, then will 'state medicine' have been thoroughly established throughout the United States, never to be displaced because of the political patronage involved. And when veterans or their relatives no longer abound, then will the free hospital service be extended to other citizens; and by 1960 the private medical practitioner and the neighborhood hospital may largely have passed out of the picture.

"None can successfully deny, it is believed, that the Federal government, by the policy herein complained of, is in unfair competition with private physicians and the supporters of local hospitals who in turn are taxed to finance this paternalistic, bureaucratic form of medical and surgical hospital and dispensary practice."

HOW TO CHOOSE A CHIROPRACTOR IN INDIANA

The September issue of the Journal of the Indiana State Medical Association contains the following item:

"A woman routist traveling through one of our Indiana cities called up a leading surgeon and said: 'I understand that you are the leading surgeon in this community, and being a stranger in the city I would like to obtain some trustworthy information from you. Can you give me the name and address of the leading chiropractor?' The surgeon retorted, 'You don't need the address of a chiropractor; you need to make the acquaintance of the superintendent of the feeble-minded school.' "

The same Journal also comments on how to choose a doctor as follows:

"The *Literary Digest* for May 30, 1931, makes some pointed comments on the subject, 'How to Pick a Doctor,' and intimates that a stranger in a strange city, unless he uses unusual discernment, is just as apt to pick a quack as a reputable physician. We confess that we consider the question not easy to answer, although we believe that a stranger in a strange city will not make any serious mistake if he calls up the superintendent of the leading hospital and merely requests that the most prominent general physician or specialist on the staff be asked to give him attention."

Equipped office of the late Dr. L. G. Distler, 11 South Street, Middletown, N. Y., who was in general practice for 25 years. Address Mrs. Distler.

ZINC OINTMENT

E. Kromayer (in the Neue Deutsche Klinik 11, 1929) applies a zinc oxide ointment containing 2 to 10 per cent Lenigallol (triacetylpyrogallol) on the diseased eczematous areas. The effect obtained by the Lenigallol in the zinc ointment is a mild cauterizaton of the diseased areas, due to the gradual liberation of its pyrogallic acid constituent. "Because of the simplicity of application and certainty of its action, Lenigallol is of great service for ambulatory patients."

Lenigallol-Zinc Ointment 6% is a practical means for the application of Lenigallol in the treatment of all types of eczema, excepting only those of an acutely irritant character. It possesses the three properties looked for in a remedial agent for the local treatment of eczema, namely to allay itching, a persistent reduction of the moist, affected areas, and lastly, the promotion of normal epidermization. Lenigallol and Lenigallol-Zinc Ointment are "Council accepted."

Literature and sample tube of Lenigallol-Zinc Ointment may be obtained by writing BILHUBER-KNOLL CORP., 154 Ogden Avenue, Jersey City, N. J.—See Front Cover—*Adv.*

COCOMALT CLINICS

Some time ago R. B. Davis Co. cooperated with health authorities* in Arkansas in an unusual test. Cocomalt clinics were established in the drought area and the children placed under the care of an attending physician and registered nurse. The children were given Cocomalt mixed with milk once a day. The average gain for forty days was 8½ pounds per child. One of the most outstanding features of this work was that in thirty children that were checked an increase in hemoglobin from 5 to 15 per cent was indicated.

The splendid results obtained with Cocomalt in Arkansas with only one feeding a day are further evidence of the high nutritive quality of this delicious food drnk. Though it provides all the varied nourishment of a well-balanced meal, Cocomalt imposes no digestive burden. It is readily assimilated, quickly metabolized. It contains malt enzymes whch actually help to digest the starches of other foods. Cocomalt meets ideally the demand for a high caloric, easily digested food.

More and more doctors are advising Comomalt in cases of malnutrition; for expectant and nursing mothers; for convalescents and for hyper-nutrition in post-operative cases. Cocomalt is available at grocery stores everywhere in the ½-lb., the pound and the economical 5-lb. family size. High as Cocomalt is in food value the cost is surprisingly low—it is within the means of practically every family.

*The Cocomalt clinics were conducted, and reports rendered, by Dr. A. M. Gibbs, Hamburg, Arkansas, and other county health officers.

Dr. J. C. Miller, Desha County Health Officer (Desha County, Ark.), writes as follows: "We used Cocomalt with milk and had very satisfactory gains and I believe Comomalt to be very valuable as a flesh producer." —See page xxi.—*Adv.*

LIVER EXTRACT—LILLY

Of interest to all medical men is a recent news item from Indianapolis announcing plans for the construction of a new medical research laboratory by Eli Lilly and Company. Ground was broken about October first. Originally it had been planned to start construction next spring. On account of the labor situation it was decided to advance the work which will give employment to a large number of men throughout the winter months.

For some years Eli Lilly and Company have placed special emphasis on medical research. Eighteen years ago a fine new building was erected to house the staff and equipment of a scientific department. As opportunities presented themselves the work of this division of the business has expanded until the facilities were no longer adequate to the needs of the company.

Eli Lilly and Company are authority for the statement that this new research unit will be the finest of its kind in the country. It will be four stories above ground. The dimensions will be 222x50 feet with an auxiliary building at the rear 84x50 feet. The structure will be of monumental design, of reinforced concrete with brick exterior.

The building will house the latest and most advanced scientific equipment. It is said, on good authority, that the value of the interior furnishings and laboratory apparatus will greatly exceed the cost of the building. Another feature of this new Lilly medical research unit will be a very complete scientific library which will occupy the top floor of the building. It is interesting to note that in addition to the present science building the company also maintains research laboratories at its biological plant outside of Indianapolis and also at the Marine Biological Laboratories, at Woods Hole, Massachusetts, during the summer months.—See Color Insert.—*Adv.*

VITAMINS A AND D AT THEIR BEST

For vitamin A therapy, Mead's Standardized Cod Liver Oil continues to be 4 to 11 times as economical as cod liver oil concentrates. *For vitamin D therapy,* the new reduced price of Mead's Viosterol when prescribed in the original 50 c.c. bottle, makes it less expensive to the patient than Mead's Standardized Cod Liver Oil or any cod liver oil concentrate. Samples on request of Mead Johnson & Co., Evansville, Ind., U. S. A. See page xxix—xxvii—*Adv.*

CREST VIEW SANATORIUM

Charmingly located, beautifully appointed; in the hilly country one and a half miles from Long Island Sound where the air is tonic. Quick drive from New York City. Truly homelike, no institutional appearance. See page xxvii.—*Adv.*

NEW YORK STATE
JOURNAL of MEDICINE

PUBLISHED BY THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

VOL. 31, No. 21 NEW YORK, N. Y. NOVEMBER 1, 1931

THE PRESENT STATUS OF QUINIDINE THERAPY*

By EDWIN P. MAYNARD, JR., M.D., BROOKLYN, N. Y.
From the Department of Medicine, Brooklyn Hospital, Brooklyn, N. Y.

QUINIDINE sulphate has now been in use in the treatment of various irregularities of the heart for thirteen years. Frey,[1] in 1918, was the first to describe its action in auricular fibrillation and since that time over one thousand cases of this disorder treated by this drug have been reported in the literature. Quite naturally its effect has been tested on other forms of arrhythmia. Scott,[2] in 1922, was the first to use quinidine in preventing and abolishing paroxysms of tachycardia of ventricular origin. Other workers have reported their experience with it in auricular paroxysmal tachycardia, auricular flutter and premature contractions so that now we are in a position to evaluate quinidine sulphate as a means of combating these conditions.

First, let us consider its use in the treatment of chronic auricular fibrillation. From the results of a study of our own cases, published in 1928,[3] those of Viko, Marvin & White,[4] Wolff & White[5] and Eismayer,[6] it is quite certain that sinus rhythm can be established in from 50-70 per cent of the cases of chronic auricular fibrillation. When considering the present status of quinidine therapy, one of the first questions to be answered is, of what value is the return of sinus rhythm to the patient? All workers familiar with quinidine agree that there is no evidence that the drug influences the natural progress of the underlying disease, or that it prolongs life. However, in a large number of people with auricular fibrillation, their chief complaint is that their activities are curtailed by the tumultuous beating of their hearts. Even when under proper digitalis control, this annoying symptom persists. It is true that there is a definite group of cases of chronic auricular fibrillation who are not conscious of the condition and in whom digitalis therapy is enough to keep them comfortable. However, for the larger group who complain of the irregular action of their hearts, quinidine therapy offers, not a cure, but symptomatic relief in from 50-70% of the cases.

As already stated, we studied a series of 53 cases of auricular fibrillation from the wards and private service at the Brooklyn Hospital. The work was completed in 1927. At the end of the study there were thirteen of the 53 cases still maintaining the sinus rhythm that had been established by quinidine. Of these thirteen patients we have a complete record on eight. All but one of the eight, have relapsed permanently to fibrillation. The one exception maintained sinus rhythm until his death in 1930. Three are alive but in permanent auricular fibrillation. The remaining four are dead and all had relapsed to fibrillation. It is of great importance to note, however, that of the eight cases successfully followed, six had long periods of regular sinus rhythm. One lasted for 8½ months—one for 21 months and two for 3 years—one for 4¼ years and one for 7 years until death. There is no evidence that the course of the disease was influenced by the treatment but there is abundant testimony that these patients were kept more comfortable for long periods of time.

Having demonstrated the value of quinidine sulphate in the treatment of certain cases of auricular fibrillation, it then becomes necessary to establish certain criteria for the selection of those cases in whom the drug should be tried.

First of all it should only be used in those cases in whom it seems desirable to abolish the fibrillation for the symptomatic relief of the patient. If the patient is not conscious of his irregular heart and if his activity is not limited thereby, quinidine is not indicated.

Second, the most favorable cases are those in whom the fibrillation has been of short duration, one month or less. Cases of longer duration than this do not show as high a percentage of successes, but are nevertheless not excluded on this ground alone.

Third, those cases are most favorable that have no signs of congestive heart failure or in which

*Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 3, 1931.

the signs of failure have responded well to digitalis. Those cases in which digitalis has failed to clear up the failure should not be given quinidine sulphate.

Fourth, patients with advanced mitral stenosis do not do well with quinidine. The fundamental pathology is so extensive in the heart that the likelihood of maintaining sinus rhythm is not very great. Furthermore the accompanying dilitation of the auricles makes the presence of auricular thrombi more probable and increases the danger of embolism.

Fifth, even in the absence of mitral stenosis, a history of previous embolism contraindicates the use of quinidine.

Having discussed the criteria for the selection of patients for whom an attempt is to be made to abolish auricular fibrillation it may be of interest to enumerate certain other factors that influence the success of the treatment. Age seems to play a definite part. According to White & Wolff,[5] those patients under forty gave a higher percentage of successes. At the same time, etiology, when related to age seems to influence the outcome. The younger cases of rheumatic heart disease did the best in their series, whereas, the older patients with arteriosclerotic heart disease did the poorest. Hurxthal[7] studied the use of quinidine in cases of fibrillation of thyrotoxic origin in whom the fibrillation persisted after thyroidectomy. He was able to establish sinus rhythm in all but five of his series.

The question as to whether digitalis should be used in conjunction with quinidine is still open to debate. There is no disagreement as to the fact that congestive failure must be thoroughly treated and that the ventricular rate must be well controlled by digitalis before the use of quinidine is begun. At this point the earlier writers felt that digitalis should be stopped, basing their opinion upon the fact that digitalis tends to increase the rate of the circus movement while quinidine tends to slow it. More recently, White & Wolff,[5] have brought forward considerable evidence to show that the response to quinidine is better in those cases that have been thoroughly digitalized. The theoretical considerations involved are very complicated but suffice it to say that the use of digitalis during the course of quinidine therapy is justifiable.

In the matter of dosage and method of administration of quinidine sulphate there is also some divergence of opinion. The drug is given in capsule or tablet form. The first day the patient is given two small test doses of 0.2 gm., each to determine the absence of quinidine idiosyncrasy. If none of the symptoms of cinchonism develop, the next day the patient is given 0.4 gm. of quinidine every four hours—day and night—after the method of Riecker[8] or 0.4 gm. every two hours for five doses as advocated by White.[5] If auricular fibrillation persists, the dosage may be cautiously increased up to 0.6 or 0.7 gm. at a dose. If the larger doses fail to restore sinus rhythm it is advisable to discontinue the drug at the end of two or three days of the heavy dosage and allow the patient to rest for two days on digitalis alone. Then a second course of quinidine should be given omitting the test doses. It has been found that quite a number of cases will revert to sinus rhythm in the second or even third course of the drug. As to whether the two hour or the four hour method of administration is the better it is impossible for us to say. The two hour method has the advantage that the patient is not disturbed for medication at night.

The maximum total dose of quinidine that can be given with safety in twenty-four hours has not been completely established. The earlier workers set the limit at 2 gms. In our series we found that it was sometimes necessary to give considerably more than this before sinus rhythm could be established, as much as 3 or 4 gms. a day in some instances.

The toxic effects of quinidine have been thoroughly described by many authors and they need only to be enumerated here. In the milder group of symptoms may be placed nausea, dizziness, headache, tinnitus, palpitation, vomiting, diarrhea and urticaria. These manifestations call for caution in the dosage but do not demand discontinuing the treatment. The more serious toxic effects are as follows, respiratory embarrassment with or without loss of consciousness, toxic rhythms, such as ventricular paroxysmal tachycardia, standstill of the auricle due to intra-auricular block and sudden collapse with death. Embolic phenomena with resulting hemiplegias may also follow quinidine therapy but are due to the dislodgement of intracardiac thrombi rather than to toxic action of the drug. These serious sequellæ are by no means rare in the treatment of chronic auricular fibrillation but they are apparently becoming less frequent as the cases are more carefully selected and as the use of the drug is better understood. Nevertheless, because of them, the attempt to abolish chronic auricular fibrillation by quinidine should be limited to hospital practice where the patient can have the closest kind of observation aided by frequent electrocardiographic tracings.

After sinus rhythm has been established it is wise to give the patient a daily ration of 0.2 gm. of quinidine three times a day for several weeks or months after leaving the hospital. This is done in the effort to prevent relapses to fibrillation.

All authors agree that quinidine sulphate is of real value in preventing or greatly reducing the attacks in paroxysmal auricular fibrillation. Wyckoff & Ginsberg,[9] reported three successful

cases in 1924. White,[10] Christian[11] and others recommend its use and so far as can be learned from the literature, agreement is complete that quinidine is a real addition to our armamentarium in the treatment of this condition. The dosage is small, 0.2 gm. three times a day and therefore the danger of serious toxic symptoms from the drug is negligible. The frequency of attacks can be greatly reduced in some instances from once or twice a week to once or twice a year. Furthermore some patients learn to terminate their attacks with one or two capsules of quinidine. The drug can be recommended as a safe and effective means of treating the paroxysmal type of auricular fibrillation.

Quinidine in auricular flutter does not enjoy the same reputation. Our own limited experience with it and that of others go to show that it is not often effective in ending the paroxysm. However, it may be tried if digitalis fails, using the same dosage as in the case of chronic auricular fibrillation. In some instances if the flutter has been converted to fibrillation by digitalis and if then the fibrillation tends to become fixed, quinidine may be of value in restoring sinus rhythm.

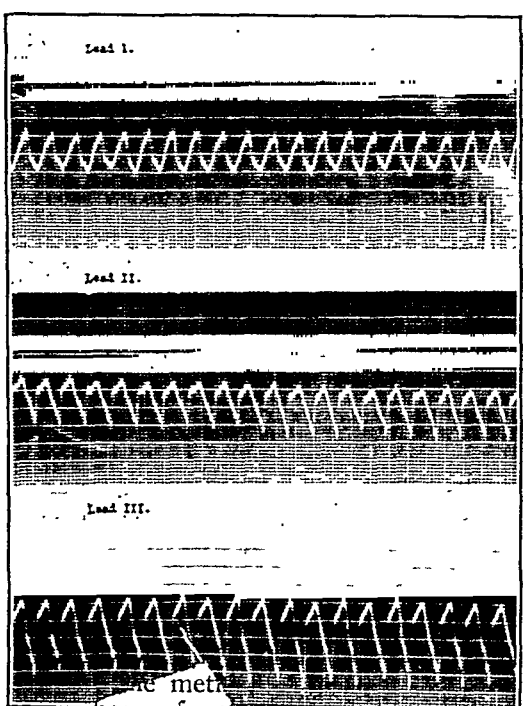
Next, we come to the use of quinidine in the paroxysmal tachycardias. Those that arise from ectopic foci in the auricles or in the junctional tissues may usually be stopped by the various methods of vagus stimulation and they rarely present serious difficulties. We have never found it necessary to resort to quinidine either to end an attack or to prevent recurrences. The tachycardias of ventricular origin are an entirely different matter however. They do not respond to vagus stimulation and they are nearly always associated with serious organic disease. All the older methods of treatment have been unsatisfactory and unless the attacks stopped spontaneously, serious heart failure and even death resulted. Scott, in 1922,[2] was the first to use quinidine in preventing and terminating attacks of ventricular tachycardia. Levine & Fulton,[12] have since confirmed his work and have called the attention of the profession to this real therapeutic agent. Since ventricular tachycardia is usually associated with serious organic heart disease, commonly with coronary thrombosis and since its results are so disastrous, no time must be lost once the diagnosis is made. The usual test doses are given and then the therapeutic doses the same day. Our practice has been to begin with 0.4 gm. every 4 hours and after one or two doses to increase the dose by 0.1 gm. at a dose until the paroxysm has been broken up. Levine recommends pushing the dose up to 1.5 gm. every 4 hours, if necessary. We have had the opportunity to treat three cases of ventricular tachycardia, two in young patients with cardiac enlargement of unknown etiolgy and one in a case of coronary thrombosis. In all three we were able to terminate the paroxysms, in the first two patients on two separate occasions each.

In order to illustrate the value of quinidine sulphate in ventricular tachycardia, one of our cases will be reported in detail.

S.M.N., age 29, male. Admitted to the Brooklyn Hospital, Jan. 30, 1929, and discharged February 9th, 1929. In his past history the patient gave no record of any of the rheumatic diseases except for two attacks of tonsillitis. Venereal disease was denied and the blood Wassermann was negative. The first attack of ventricular tachycardia was three years before admission after a game of tennis. Since then he has had two or three attacks a year always lasting less than twenty-four hours. Between attacks he is entirely free from cardiac symptoms. Physical examination then, reveals a heart which shows moderate general enlargement, a regular rhythm, no signs of valvular disease and no signs of congestive failure.

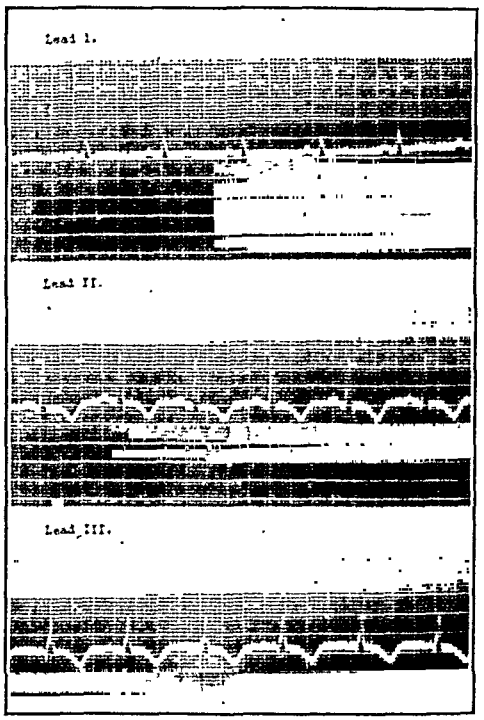
Diagnosis—cardiac enlargement, etiology—unknown. The attack to be described began January 29, 1929, but failed to subside in the usual manner. The heart rate was 230 per minute, blood pressure 90 systolic—70 diastolic. The patient was pale, anxious, sweating and troubled by attacks of vomiting and vague precordial distress. Electrocardiograms showed ventricular tachycardia. As the attack progressed the heart became larger to percussion, the liver became palpable and tender, 4 centimeters below the costal margin and numerous fine moist rales appeared in the anterior chest. After trying vagus pressure, without success, using large doses of morphine and other sedatives it became apparent that further measures must be taken to stop the paroxysm as congestive failure with pulmonary edema had begun. It was decided to use quinidine sulphate and the first dose of 0.4 gm. was given January 31st, at 8 P.M., and continued every four hours. After the 4th dose, or sixty-three hours from the onset, the paroxysm ceased. The signs of congestive failure rapidly cleared up and the patient recovered. There have been two recurrences since then, one in March, 1929, which was treated successfully at home and another in August, 1930. This attack was a severe one, the worst of all but was finally controlled by quinidine. Since then and to date the patient has been free from attacks. We have had no experience with quinidine sulphate intravenously but its use in this way has been reported. In serious situations, such as ventricular tachycardia, if quinidine fails by mouth, it would seem justifiable to give it intravenously. The dose recommended is from 0.2 to 0.4 gm. every 4 hours. Undoubtedly the most striking and dramatic results of the use of quinidine sulphate are seen in ventricular tachycardia.

There is one more use for quinidine in the



arrhythmias and that is in the treatment of premature beats. Ordinarily after careful examination has excluded organic heart disease, simple reassurance is enough to satisfy the patient. If the exciting cause of the irregularity cannot be found and eliminated, sodium bromide is usually the best remedy. Digitalis may also be useful in some cases. If these measures fail, small doses of quinidine sulphate 0.2 gm. three times a day may suffice to make the premature beats very infrequent and relieve the patient of their annoyance. There is a considerable group of people, however, in whom quinidine is unsuccessful.

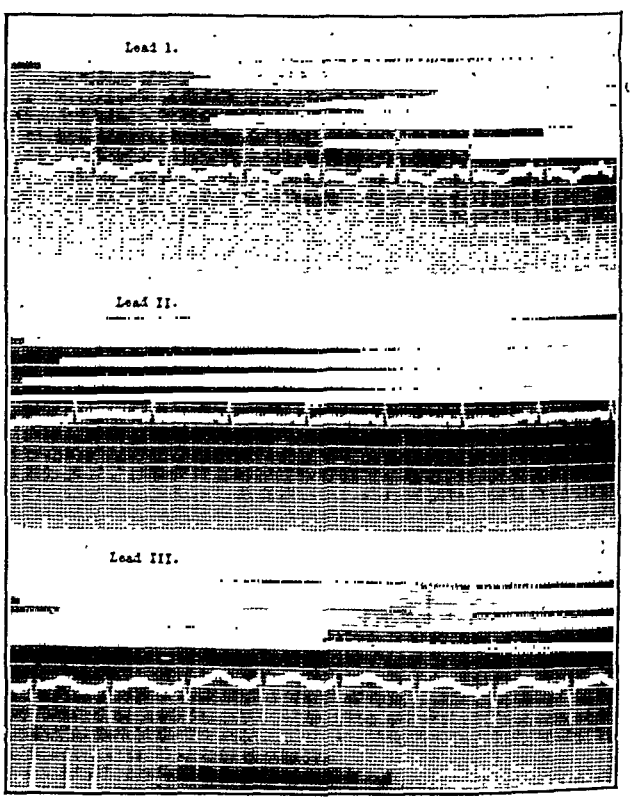
Summary



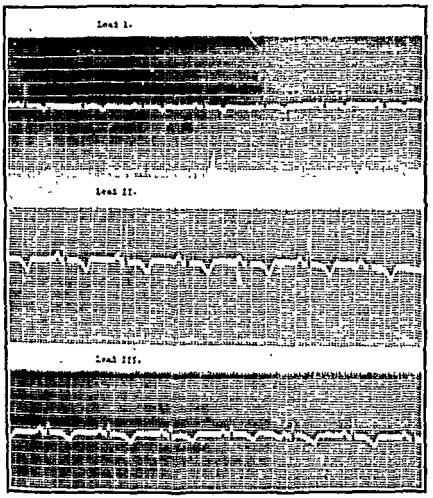
1. The use of quinidine sulphate in the treatment of chronic auricular fibrillation is described. The criteria for the selection of cases are discussed and the end results in our series of cases reported in 1928[3] are given. In properly selected cases quinidine sulphate is recommended in the treatment of chronic auricular fibrillation for the relief of the symptoms arising from the irregular action of the heart.

2. In the paroxysmal type of auricular fibrillation, quinidine sulphate was found to be highly successful in abolishing or greatly reducing the frequency of the paroxysms.

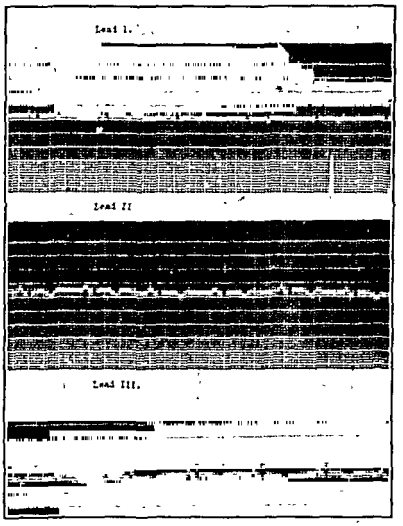
3. Auricular flutter does not respond so well and quinidine is only recommended in those cases in which digitalis has failed or in which the flutter has been converted to a type of fibrillation that does not readily revert to sinus rhythm.



Jan. 30, 1929. Ventricular Paroxysmal Tachycardia—before quinidine administration.



Feb. 1, 1929. Sinus rhythm after quinidine sulphate 1.6 gm. Note the deep inversion of T in leads II and III. No axis deviation.



4. In the paroxysmal tachycardias, quinidine sulphate is rarely necessary in the auricular or

THE GUTTADIAPHOT TEST*

By ISTVÁN GÁSPÁR, M.D., ROCHESTER, N. Y.

THE guttadiaphot is a new test for the detection of pathological changes of the blood. The name, guttadiaphot, means picture of a drop seen by transmitted light. The starting point of the whole idea was a fortunate observation of Meyer, a practicing physician in a country town. He observed a different behavior of the blood when a few drops were drawn into the salvarsan syringe, namely, the blood either sank or floated in the salvarsan solution, the first condition being in connection with a positive, the latter with a slightly positive or negative Wassermann reaction. Meyer tried to utilize this observation and simplify the Wassermann reaction, but the method did not work out in practice. Later on absorbent papers were used and the blood was dropped on them. Meyer stained the absorbent paper with sudan red, because he thought of catching the lipoids of the blood; while Bierast introduced a malachite green and an ocean blue stained paper strip. At this time the idea of substituting the Wassermann reaction was abandoned, and the thought was to bring out certain qualities of the blood in different diseases. Schilling replaced the third paper strip with a nile blue stained one and experimented on an abundant clinical material. He showed that the test is unspecific, but is a general and very sensitive indicator of disease.

The technic of the test is very simple. Three test papers, red, green and blue are placed in a little pasteboard frame, and kept ready for use in a dried condition. About one cc. of blood is withdrawn from the cubital vein with a perfectly dry syringe and needle. Immediately afterward two drops of blood are allowed to fall on the same spot on each of the test-papers. The blood drops will spread in a circular fashion. Now, the papers are kept in a horizontal position until the blood drops become dry. Technical mistakes should be avoided, because positive pictures may be simulated in a normal blood. Moist frames, or water mixed with the blood will cause much confusion.

The papers are read a few hours later; however, the blue strip is very often characteristically positive a few minutes after the test has been made. The dried drops are examined by transmitted light, by looking through them. The light is furnished either by daylight or by an electric bulb.

The healthy blood shows a characteristic picture. On the red strip, there is a dark red outline of the blood disc. The disc may be surrounded by a corona, which again is circled by a dark edge.

On the green strip, the disc is of a brownish red color and homogeneous. A corona with a sharp outline is not regularly observed.

On the blue strip, the reddish-green disc is bordered by sharp outline.

The picture of pathological blood presents numerous variations. The sharp edge of the disc may be repeatedly broken. There may be no distinct contour whatever, or a bright red corona without a sharp contour especially on the red strip.

The blood disc may clear up, indicating solution of the dyes in the blood, suggestive of anemia. In such instances the disc is lighter in color and may be mottled. An accumulation of color near the edge is most distinct on the blue strip. It appears here as a dark green edge, especially if viewed from above. Very strongly positive cases (sepsis, blood diseases, advanced syphilis, and tuberculosis) are accompanied by the formation of free light colored rings around the blood disc. This is due to the dissolved dye which has been carried beyond the extent of the red blood corpuscles. From a practical point of view the free colored rings mean pernicious anemia, but we have found an exactly similar picture in a case of undetected prostatic carcinoma with metastases to the ribs. The various discs represent only different gradations but not differential pictures.

In the mechanism of the reaction the red blood corpuscles are extremely important, because the blood serum or cerebrospinal fluid alone does not show different guttadiaphot pictures in healthy or diseased conditions.

Other factors which may have some important role in the reaction, are, electrolytic content, viscosity, surface tension of the serum and solubility of the dye in different serum components, and lipoid content of the serum.

According to Schilling a positive guttadiaphot indicates active infectious or anemic conditions or an endocrine blood disturbance (for instance due to hyperthyroidism) provided that physiological conditions, such as menstruation and pregnancy or faulty technic may be ruled out. In infections a positive guttadiaphot practically means activity. In chronic infections the test is more sensitive than the sedimentation reaction. In infectious conditions the anemia is also important to get positive reactions, but the parallelism is not absolute. Namely, there is a marked positive reaction even without a remarkable anemia in these conditions.

In a large majority of cases syphilis gives a

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 3, 1931.

positive guttadiaphot reaction. It also became evident that in a suspicious case of syphilis the guttadiaphot may almost be equal to the Wassermann reaction. This does not mean, however that it can be used as a substitute for the Wassermann reaction. Almost all cases of tuberculosis, which were reported, showed positive pictures. Mild, ambulant cases were similarly positive when tested with this method.

Anemias occurring in blood diseases give a strongly positive reaction. During the course of liver therapy the pathological pictures of pernicious anemia gradually return to normal, though marked neurological symptoms still may be present. Leukemias may give a negative reaction before anemia complicates them.

Non-infectious, internal diseases, especially unaccompanied by anemia or without endocrine disturbance show negative guttadiaphot pictures. An early diagnosis of malignancy by this test is impossible because the resulting blood changes are at first not remarkable.

In neurasthenia, neuroses, climacteric complaints, simulations and in health examinations a negative guttadiaphot confirms the functional nature of the complaints.

Our own experience, gathered at the Klinik of Prof. His in Berlin, and the results obtained in more than fifty selected cases at the Rochester General Hospital, showed that a negative guttadiaphot test was helpful in substantiating the functional nature of complaints in visceroptosis, in adult and child hysteria, in a case of fractured costal cartilage simulating gall bladder disease, and in a case of neurasthenia. On the other hand, a case of duodenal ulcer showed a positive picture with normal blood count, and a case of enlargement of the thyroid associated with nervousness presented a markedly positive reaction opposite to the basal metabolic rate, which was normal. In this way the functional nature of the nervousness was ruled out.

Though the test does not localize the disease and the reaction is uniform in widely different conditions, it is a valuable addition to our practical tests. It seems that the test will be used with success in the hospital and in the out-patient department. It seems, however that the practicing physician will gain much more.

With a simple office test his attention may be called to the presence of pathological conditions which might otherwise be overlooked. He may also use the test at the periodical health examinations or in compensation cases, and save the papers for a followup or as documents. A positive guttadiaphot will urge him to carry out more specific tests.

A SPLINT TO PREVENT TOE DROP IN POLIOMYELITIS

By T. WOOD CLARKE, M.D., UTICA, N. Y.

THE most important factor in the early treatment of poliomyelitis after paralysis has set in, is the prevention of deformities. The most common cause of deformity is the weight of bed clothing and gravity in cases of paralysis of the muscles of the leg, causing toe drop and resultant contraction of the tendoachilles.

To prevent this, physicians have made use of frames to hold up the bed clothing, boxes or sand bags below the feet, and bandages, splints, and plaster of Paris.

The frame, while keeping the clothing away from the toes does not offset the effect of gravity. Boxes and sand bags necessitates constant adjustment and immobility of the patient, a difficult accomplishment in children if the paralysis is not extensive. Bandages have too much play. Plaster of Paris is heavy and the ordinary ankle splints require the keeping in stock of a variety of sizes.

For the last fifteen years the author has been using a splint which combines rigidity and lightness, and can be made in a few minutes at the bedside to fit the individual case.

The material used is the fibre board* used by electricians. For a small child the board 1/32 inch in thickness is used. For adults 1/16 inch board is better. This fibre board has the characteristic of being very stiff in its normal condition, but after soaking in hot water for a few minutes it becomes soft and pliable. The large sheets can be soaked in hot water, cut into strips and rolled up into tight rolls which can be carried easily in a bag.

When the splint is to be made, a measurement is taken from one inch beyond the toes, over the heel, to the upper third of the calf. The roll of fibre board is soaked in hot water until it softens and unrolls, cut to the required length and width and the corners rounded off. A perpendicular cut is made opposits the tip of the heel from both edges, the two cuts coming to a point one to two

* The fibre board used by the author is that made by the Spaulding Fibre Co., Tonawanda, N. Y., and sold under the title of "black vulcanized fibre."

Lower: Completed Splint.

inches from each other according to the size of the patient. The splint is then bent at this point until it naturally stops at a right angle. The flap from the leg end should be outside, making a flat support for the heel. Near the upper edge of the angle so made, the two layers are held together by an eyelet applied with eyelet pliers** purchasable at any stationer's store. Usually one such eyelet at each side is all that is required, but for a large splint two may be needed.

Other eyelets are then inserted along the free edges of both the foot and leg portions of the splint through which are run shoe laces.

If the eyelets and eyelet pliers are not obtainable, the angle can be held in place by making several holes with a leather punch through both layers of fibre board and lacing these up with a shoe lace, and the holes for lacing the "shoe" may be made in a similar manner. These, however, do not hold the splint so firmly and the sharp edges of the fibre board, after drying, may cut the laces.

The leg and foot is then wrapped in absorbent cotton and bandage for warmth and protection, or if preferred, several thick stockings may be put on, the splint is applied and is laced up while still comparatively soft. It is well for a few hours to bind a small block or box to the sole of the splint to insure its flatness.

This splint being applied when the material is soft can be made to fit any foot, and in a few hours it becomes almost as rigid as steel. If the fit is not accurate, the splint can again be softened in hot water and remoulded to fit. Care must be taken that the heel slits are long enough so that the back of the heel is curved, not flat, as a flat heel may cause painful pressure against the child's heel. If this occurs the splint can be resoaked in hot water and a window cut in the back of the heel. The completed splint for a child of two years weighs one ounce and a half. These splints are intended for use only while the child is in bed or in a chair. They do not take the place of braces after the child is walking about.

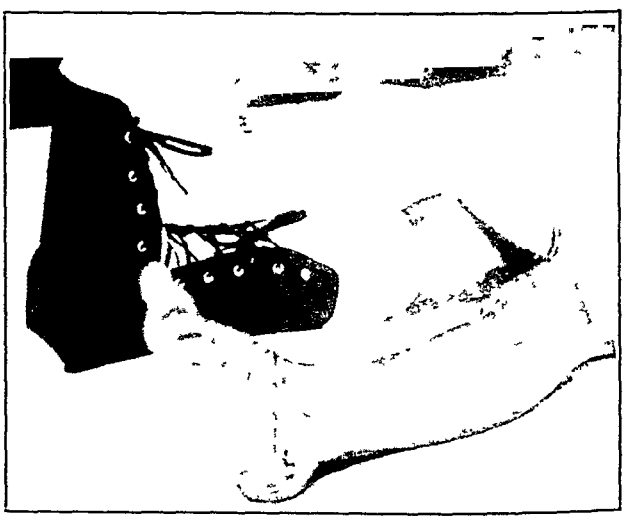

FIGURE 2
Splint Applied.

The accompanying illustration shows the materials used and the completed splint. The only other requirements are a pair of shears and a basin of hot water.

While the author has used this method of making a splint, especially for ankle splints in poliomyelitis, the same method can be used by surgeons and orthopedists in making splints for elbows or forearms.

WHAT HAS MODERN PROGRESSIVE PSYCHIATRY TO OFFER TO THE TEACHER-IN-TRAINING?*

By FREDERICK L. PATRY, M.D.

Neuropsychiatrist, State Education Department, Albany, N. Y.

IN a current editorial of an Albany newspaper the Prince of Wales's recent visit to South America was discussed in some detail. The Prince noticed that at least two things were necessary to success in selling goods for England. First, you must have what the people want and, second, you must let them know that you have it. Furthermore, he told a gathering engaged in trade and manufacture that "We must adopt, adapt and improve." The editorial wound up by stating that if your business is worth advertising (the art of transferring an idea from your mind to millions of other minds), get the best advertising agent you can to work at your problems. If you decide that your business is not worth advertising, advertise it for sale.

You, who represent the best fruits of the noble profession of teaching, may rightly protest that it is a far cry from the world of so-called "business" to that most important of all undertakings —the education of our nations most precious asset, its children and youths. Yet, I would ask your kind indulgence to reflect a moment on those somewhat mundane remarks of the Prince to consider if there is perhaps a modum of truth that might apply to some of the ramifications of progressive trends in education today. I refer particularly to the wisdom and perhaps necessity of "adopt, adapt and improve."

My purpose in joining with you today on this delightful occasion is not to beat the big drum in advertising a certain brand of psychiatry, but to communicate to you in brief a few of the rock-bottom, experience-born facts of common sense psychiatry as far as it is utilizable by those who have consecrated their lives to work with our school and college pupils.

What has psychiatry to offer our teachers-in-training? Allow me to arbitrarily select three aspects for you to mull over. First, practical psychiatry has to offer the student-teacher an important *point of view* regarding behavior and its deviations. Second, psychiatry has considerable worth while *information*, gleaned from years of diagnosing and treating the mentally ill, which may profit our students in their inevitable contact with such sick persons. Third, psychiatry can not only sensitize the teacher to *recognize* the importance of varying aberrations in mental health, but how to *help in handling* such problems in a more intelligent and fruitful manner.

If these three aspects of psychiatric contributions to education are absorbed and lived out by our teachers, there will be little room for such remarks, as I received this week by one of this nation's foremost psychiatrists, namely, "as a rule teachers are less socially minded than any other biological organism that I have met—at least among the vertebrates." Again within the past year, one of the world's most authoritative psychoanalysts, remarked to me that judging from his experience with teachers he has come to the conclusion that the pedagogue may be defined as a person who perpetuates his prejudices from one generation to another.

To what extent are such impressions true or justifiable? Are we as teachers too concerned in removing the mote from the eyes of our charges to the neglect of realizing our own defects and shortcomings?

As concerns the modern psychiatric viewpoint, let me first assure you that psychiatry has no dogma to offer. It builds upon a willingness to learn from experience and through creative experiment. It does not foster the "I tell you so" attitude. It claims no exclusive road to salvation. It begins with those who come to the physician on their own initiative, or that of others, because they are in trouble. It begins with the differences and variations in behavior in the intellectual and emotional tendencies, the lasting traits, the temperament and character, and the capacity to accumulate and use experience in their adjustment to life as they have to meet it.

The educator will immediately observe that the object of our problems are growth—and time-determined; that the body and minds with which we have to deal have a dynamic-genetic background, largely the result of environmental and educative influences of one sort or another. It is upon this common ground that the educator and the psychiatrist join hands in shaping the multifarious factors entering into the life development of our teachers and pupils.

In order to avoid arousing any discomfort in you by breaking cardinal principles of the science of education, I shall attempt to proceed from the known to the unknown and bring to the front the more concrete before branching off to the abstract. In view of the short time at my disposal my remarks will of necessity be of a general nature, although the specific aspects have not been lost sight of.

Dr. Charles E. Benson and Miss Louise E. Alteneder of the School of Education, New York University, have recently completed a survey of Mental Hygiene in Teacher-Training Institutions in the United States. It is a matter for congratulation to note that of the larger States of the Union, New York is easily in the

* Address before the New York State principals of Teachers Colleges and Normal Schools, Lake Mohawk, N. Y., May 23, 1931.

lead in the combined number of Teachers' Colleges, State and City Normal Schools and Private Institutions reporting regular courses and special lectures in Mental Hygiene.

Of our two Teachers' Colleges one reports special lectures; of eight out of nine of our State Normal Schools which sent data, two report regular course and five report special lectures; of our five City Normal Schools, one reports a regular course and five report special lectures; of seven out of eight private institutions sending data, three report regular courses.

It will be noted that the private institutions have a higher ratio of regular courses in Mental Hygiene than either the State or City Normal Schools or Teachers' Colleges. This is in keeping with the general tendency throughout the country for private institutions to have a higher percentage reporting psychiatric help available, mental hygiene clinics accessible, and opportunity for visiting institutions for feebleminded or other exceptional children.

Furthermore, this report brings to light the following facts:

A large and increasing number of teacher-training institutions realize the need and importance of including Mental Hygiene in their courses of study; in the introduction of courses in mental testing, and for teachers of mentally deficient and maladjusted children; in the recognition of the importance of mental hygiene and child-guidance clinics and in the increasing use of literature in the field of mental hygiene. In the large majority of these institutions the work of mental hygiene is under the department of psychology or in connection with work in that subject. In a number it is a part of the general health program. For the most part these courses are elective and are offered in the junior and senior years. The importance of reaching the pre-school child, and of educating parents, in order to make mental hygiene effective in the schools, is being more and more recognized by teacher-training institutions.

As compared with a similar survey made by Dr. Wm. H. Burnham in 1921, the present survey brings out the following data:

Emphasis in the field of mental hygiene has shifted from the abnormal to the normal, from the problem of treatment to that of prevention. The *individual* is becoming the focus of attention and education is striving to shape the school's curricula to the needs of the child. The significance of case studies must lie in the method and attitude employed. No two maladjustment problems can be treated alike. Environmental factors must be considered in the light of physical, mental (emotional as well as intellectual) and constitutional factors. Every teacher-training institution should include some work in the principles of mental hygiene in its curriculum. In order to keep the child normal and to adjust the maladjusted child, every teacher must apply the principles of mental hygiene in all her instruction and school relationships, and carry on her work with the mental hygiene point of view. It was the consensus of opinion that mental hygiene has given to child psychology and child guidance, and indeed all education, a new significance and greater responsibility to the work of the teacher. Richer and multifarious opportunities for pupil lifts and helps have been made known and put into daily classroom teaching experience.

Finally the survey revealed the following problems and difficulties encountered in carrying on mental hygiene work:

There is still some confusion as to just what mental hygiene covers and what needs it meets. There is some doubt as to the length and nature of a course to offer in a two- or three-year curriculum which is already overcrowded. The large amount of literature published in recent years covering various phases of mental hygiene makes it difficult to choose the best and most practical books and pamphlets for text and reference. Some institutions report that progress is impossible because of financial or administrative problems.

I merely bring the substance of this survey to you attention to give you a bird's-eye-view of the present general status of Mental Hygiene in teachers-training institutions, and not with the idea of offering a panacea for its specific problems. Perhaps the facts presented may suggest ways and means of furthering the inclusion and extension of this important aspect of education in the curricula of such institutions.

Realizing that I have already taken up too much of your valuable time, may I briefly mention what I consider to be the core of psychiatric contribution in a teacher-training-institution.

Appreciating the fact that there will always be problems of behavior, of personality difficulties and difficulties of well-being facing our teachers in the classroom, it behooves us to cause our teachers to become more psychiatrically intelligent.

In order to help others in difficulty of adjustment, the teacher must first grasp and accept the facts of her own genetic development and the many factors entering into it. Perhaps the best experience has shown that this can be most effectively developed by a thorough-going personality study of the teacher herself or of some one intimately known to her. This *personality study* should include a biographical sketch, a characterization of a few contrasting individuals, some preparation for heredity study and a general formulation of personality problems. This latter should include a general survey such as we might wish for when asked to advise and guide another person on the question of health, happiness and efficiency. This should include the enumeration and evaluation of past work, suc-

cesses and failures, daily routine and habits, recreations and hobbies, social activities, interests, strivings and ambitions, type of temperament, ratio of perception, dreaming, thinking and action, composure, estimation of self and others expectation of self and of life, and balancing the above in a satisfaction formula This personality study by the teacher should also include a special analysis of the psychological assets such as affective and emotional tendencies, topical processes, range and fluctuation of fitness with regard to the ratio of work, play, rest and sleep, social relationships, sex development and patterns, synthesis and balance of the personality, difficulties and handicaps, disappoints and reactions to them, special dynamic complexes or determining tendencies, etc

You will note that we start from what is within our immediate objective experience rather than from a text book course of more or less elementalistic and non personal experimental data We are primarily concerned in concrete performance, in what Adolf Meyer calls the experiment of nature and its reconstruction Our general formula for work in any problem is what are the facts, how do they work, how do they group themselves, under what conditions do they arise, what are the factors entering into them, what are the results, what has to be more or less accepted as unmodifiable, and what is modifiable or preventable

Applying this relativistic and inclusive formula to problems and situations which demand our attention it becomes obvious that we focus on *function* and *activity*, on the known rather than the unknown or theoretical, on the facts which have a meaning and which are *utilizable* Our perspective has a social background into which we strive to weave the maladjusted through capitalizing his assets, and balancing these with his habilities and opportunities in keeping with his capacity and needs

We would have the teacher in training realize and accept the fact that mind is not a separate entity from body Can you imagine a gastrointestinal tract or the brain stalking about without its host? Concepts of interactionism and dualism have already contributed too much in impeding the march of progress in the mental sciences It is high time that we realized that each of us reacts as an integrated unit, that mind is something more than the expression of one's intellectual faculties—reasoning, judgment, memory, and so forth Mind is the human being in action, and that action is started by a wealth of factors Mind as we use it in every day living is not something merely above the eyebrows It is you and I in action, it is the expression of the way we feel and think, it is the expression of our desires, cravings, anticipations, memories and a host of other factors—overt or implicit, involving primary and secondary symbolization We have learned that our mental life is so intricately bound up with our bodily functions of digestion, circulation, glandular activity and so forth that it would be the height of self deception to attempt to evaluate so called mental behavior without a grasp of all the facts entering into it—physical, mental, constitutional and environmental

It is very important that our students learn through their own personality study and of others that our behavior is chiefly dependent upon (1) the stuff out of which we are made, (2) the way in which environment and training—of home and school and neighborhood and church—have molded that stuff, (3) that although choice and decision mechanisms play a role in our life adjustments, we are not primarily guided by reason but by our emotions, cravings, desires and longings which often so subtly operate that our intellect is virtually hypnotized into doing almost anything they wish, (4) that habit training and habit patterns woven into the fabric of our lives during our most formative years to a large extent determine our successes and failures in adjusting to life

We perhaps copy and acquire as much as we inherit But our practical problem is what environment can give constitutional endowment its best chance of development, how may we best capitalize this experiment of nature in our midst so that we can help him to become a marketable product, a social asset

Psychiatry is not so much interested in judging behavior as it is in its interpretation—the unraveling of its causes and motivations, it is not our chief problem to classify human tendencies but to find out where they lead and direct them into wholesome, socially useful channels

The psychiatrist in the school system is not out with a spy glass tracking down candidates for a mental hospital He is primarily interested in bringing about a healthier balance of each pupil's personality integrated components in his efforts to adjust to life Where unwholesome traits and behavior characteristics show themselves, the psychiatrist concerns himself in shaping modes of approach for their modification He tackles the problems at hand without too much talk of prevention or raising alarmist ideas of what might happen if such and such a procedure is not carried out There are no reliable facts to substantiate any such program of propaganda We know that not all maladjusted or neurotic children turn out to be criminals or antisocial or "insane", and we also know that many adult delinquents and criminals and mentally sick persons showed no obvious abnormal traits when children Our chief concern is to handle in the best possible ways the problems and situations at hand

The psychiatrist feels he can be of considerable assistance in making the teacher's efforts

more effective and generally helpful through sensitizing her in the early recognition and handling of combinations of temperament and personality traits which psychiatric experience has found to be in many cases a liability and perhaps tend toward mental inefficiency or derangement. For example, experience shows that certain individuals withstand the strains of life poorly—the shy, timid, stand-offish, asocial persons, poor mixers, bad losers, those never able to talk of their difficulties, the hypersensitive, those with extreme emotional unevenness, the suspicious and exalted-ego types who fail to condescend to gain a consensus of opinion (in the sense of winning the approval of their best friends and judges) before embarking on some grandiose or revolutionary idea or program.

We want our teachers to appreciate the fact that there is no cut-and-dried formula in solving such behavior and personality difficulties; that before we can hope to guide or help them we must first have our own house in order and control; that it is absolutely essential that we learn to interpret behavior and shape our means of help in the light of individual, intellectual and personality limitations. I feel that this understanding can best be brought about by the concrete demonstration of problem children which teachers meet in their every day classroom experience; talks, lectures and writing articles are complementary but of secondary importance.

Finally let me urge upon you that no matter how vast our knowledge and so-called technique may become, we will never be able to dispense with critical common-sense. It is perhaps just as potentially dangerous to let loose upon our children highly trained teachers who have not learned to utilize trained common-sense as it is to possess the quintescence of common-sense without training.

Mr. H. L. Mencken has characterized the specialty of psychiatry as the weak-sister of medicine. Albeit, modern progressive psychiatry is rapidly becoming the cornerstone of sound medical practice. It is conservatively estimated that at least 40% to 60% of men and women who go to doctors with aches and pains are suffering from some personal, domestic, or economic worry which masquerades as a physical sensation of discomfort. Such symptoms are body protests to stress and strain of life for which the individual is inadequately prepared to meet. The proper application of efficient scientific therapy demands prerequisite thorough training and grasp of all the other biological and medical sciences in order to examine, evaluate and prescribe for the maladjusted or mentally sick person as a *total* individual.

Mental Hygiene is that aspect of preventive medicine and psychiatry which emphasizes the conservation and improvement of mental health and the prevention of mental ills of various degree. Its successful application necessitates the cooperation and sympathetic understanding of all community social agencies and especially the home, the church and the school.

The only justifications for my being a member of the State Education Department and talking with you today is to assure you that the fruits of what might be considered the best in psychiatric experience is at your disposal and that it is offered to you in the confident hope that it will be of vital service in the promotion of a larger measure of health, happiness and efficiency of our teachers and pupils.

Pestalozzi is credited with having said that the essential principle of education is not teaching; it is love. I would add that this is only of social significance in so far as the sympathy, understanding, and efforts of the teacher are successful in leading her to take a human, personal interest in each pupil under her wing, and to do her best to help him happily adjust to life in proportion to his capacity, needs, and opportunities.

THE USE OF SULPHOCYANATE IN THE TREATMENT OF HYPERTENSION*

By WILLIAM GOLDRING, M.D., AND HERBERT CHASIS, M.D., NEW YORK, N. Y.

From the Department of Medicine and the Third (New York University) Medical Division, Bellevue Hospital, New York City.

THE reintroduction of the sulphocyanates in the treatment of arterial hypertension has in recent years attracted wide attention. A number of investigators have attested to its effectiveness, in lowering both normal and abnormally elevated blood pressures. On the other hand it has been stated, that in a large group, the sulphocyanates appear to exert no more beneficial effect on hypertension than do certain so-called non-specific measures of therapy, classed under the general heading of "psychic and sedative treatment." Furthermore the great tendency toward variability of raised blood pressures and the not infrequent spontaneous remissions observed in the course of essential hypertension often render the true interpretation of any so-called therapeutic endeavor particularly hazardous.

A number of commercial drug concerns have placed sulphocyanate at the disposal of the medical profession, making positive claims for its effectiveness in hypertension but omitting or mere-

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 3, 1931.

ly alluding to its toxic properties. Ever since Claude Bernard's first pharmacological investigation in 1857, there have been many references to the toxic properties of sulphocyanate, but in examining the literature it is noteworthy that, with a few exceptions, mainly its hypotensive property is stressed. The appearance of toxic manifestations 13 times in a series of 74 trials on 50 patients under investigation by us seemed of sufficient importance to report. In two of these 13 patients there was a fatal outcome. We believe that this is the first report of death in man from sulphocyanate administered for therapeutic purposes.

A review of the literature indicates firstly, that the toxic effects of sulphocyanate in man are known and have been repeatedly observed by independent investigators; secondly, that while a given dose proves harmless and perhaps therapeutically effective in the hands of one investigator, it may produce severe and often dangerous manifestations in the hands of another.

Fifty patients with hypertension were selected and subjected to 74 different trials with sulphocyanate therapy. Of these, 69 had hypertension of the essential type and in 5, the hypertension was associated with chronic diffuse glomerulonephritis. Forty-four trials were made in the out-patient clinic and 30 were observed during a stay in the hospital wards. All blood pressure readings were made by the same group of observers. Readings were consistently taken from the right arm only and a standard mercury manometer was used. The auscultatory method was invariably employed. A satisfactory period of mental and physical rest was insisted upon before blood pressure readings were made. With the arm cuff in position, five and often more readings were made before the blood pressure level was decided upon. Where for any reason doubt existed or when a decided change from the previous reading was noted, two and usually three observers made independent readings before a final estimate of the blood pressure level was accepted. While on sulphocyanate, out-patients were seen weekly and ward patients at least once daily.

Being aware of the great tendency toward spontaneous variability of blood pressure levels, control periods were extended as long as feasible and as many blood pressure readings were made as we felt were reasonably necessary on each patient. The length of control period was principally determined by the history of known duration of the hypertension and the degree of variability of the blood pressure noted under our own observation. That is, the longer the history of hypertension as obtained from the patient and the less the variability of the blood pressure under our observation, the relatively shorter control period seemed necessary.

Both the sodium and potassium salts were used indiscriminately in our series and no record was kept of the particular salt administered to each individual patient. Such a record did not seem necessary in view of the evidence that the effective radical is the sulphocyanate only. In accordance with our stated intention of subjecting sulphocyanate therapy in hypertension to a severely strict evaluation we accepted as effective only such instances in which both systolic and diastolic blood pressures after treatment, fell to within or almost within the normal range. Furthermore it was insisted upon that the treated blood pressure must have fallen below the lowest of the control blood pressure readings within an average range of 45 mm. Hg. systolic and 31 mm. Hg. diastolic. In those instances in which we discontinued sulphocyanate before either a therapeutic or toxic effect occurred, the total amount which had been administered was with few exceptions greater than the amount frequently reported by others as an effective dosage.

In recent years a number of substances have been advocated as useful in artificially lowering the blood pressure in hypertension. Their effectiveness in this regard has not been generally confirmed. Sulphocyanate, on the other hand, has apparently met with approval among a large number of independent investigators. One fact seems true from our data; that is, that sulphocyanate will effectively lower blood pressure in one of about every three persons with hypertension. Our percentage of effectiveness (32.4%) is lower than that observed by many other investigators, probably because of our insistence upon the strict criteria of effect as stated. It seemed to us that only by adherence to such strict criteria could the effectiveness of sulphocyanate as a hypotensive drug be properly evaluated. Almost invariably fall in blood pressure was accompanied by subjective improvement. However subjective improvement occurred in many patients on sulphocyanate therapy, in whom no lowering of blood pressure occurred. This led us to believe that such improvement was largely psychic in nature Still, exclusive of toxic effects from the drug itself, no obvious harmful effects were noted from persistent lowering of a previously high blood pressure. Whether or not harmful effects occurred which were not immediately obvious, we cannot say from the data available.

In those individuals, in whom sulphocyanate was considered effective, the artificially lowered blood pressure returned to its previous level within 7 to 110 days. There was no constant relationship between the persistence of the hypotensive effect and the amount of sulphocyanate administered.

Where it is felt that sulphocyanate may be useful in a given patient the dose should not exceed 0.326 gm. (5 grains) daily. It is our expe-

more effective and generally helpful through sensitizing her in the early recognition and handling of combinations of temperament and personality traits which psychiatric experience has found to be in many cases a liability and perhaps tend toward mental inefficiency or derangement. For example, experience shows that certain individuals withstand the strains of life poorly—the shy, timid, stand-offish, asocial persons, poor mixers, bad losers, those never able to talk of their difficulties, the hypersensitive, those with extreme emotional unevenness, the suspicious and exalted-ego types who fail to condescend to gain a consensus of opinion (in the sense of winning the approval of their best friends and judges) before embarking on some grandiose or revolutionary idea or program.

We want our teachers to appreciate the fact that there is no cut-and-dried formula in solving such behavior and personality difficulties; that before we can hope to guide or help them we must first have our own house in order and control; that it is absolutely essential that we learn to interpret behavior and shape our means of help in the light of individual, intellectual and personality limitations. ly alluding to its toxic properties. Ever since Claude Bernard's first pharmacological investigation in 1857, there have been many references to the toxic properties of sulphocyanate, but in examining the literature it is noteworthy that, with a few exceptions, mainly its hypotensive property is stressed. The appearance of toxic manifestations 13 times in a series of 74 trials on 50 patients under investigation by us seemed of sufficient importance to report. In two of these 13 patients there was a fatal outcome. We believe that this is the first report of death in man from sulphocyanate administered for therapeutic purposes.

A review of the literature indicates firstly, that the toxic effects of sulphocyanate in man are known and have been repeatedly observed by independent investigators; secondly, that while a given dose proves harmless and perhaps therapeutically effective in the hands of one investigator, it may produce severe and often dangerous manifestations in the hands of another

Fifty patients with hypertension were selected and subjected to 74 different trials with sulphocyanate therapy. Of these, 69 had hypertension of the essential type and in 5, the hypertension was associated with chronic diffuse glomerulonephritis. Forty-four trials were made in the out-patient clinic and 30 were observed during a stay in the hospital wards. All blood pressure readings were made by the same group of observers. Readings were consistently taken from the right arm only and a standard mercury manometer was used. The auscultatory method was invariably employed. A satisfactory period of mental and physical rest was insisted upon before blood pressure readings were made. With the arm cuff in position, five and often more readings were made before the blood pressure level was decided upon. Where for any reason doubt existed or when a decided change from the previous reading was noted, two and usually three observers made independent readings before a final estimate of the blood pressure level was accepted. While on sulphocyanate, out-patients were seen weekly and ward patients at least once daily.

Being aware of the great tendency toward spontaneous variability of blood pressure levels, control periods were extended as long as feasible and as many blood pressure readings were made as we felt were reasonably necessary on each patient. The length of control period was principally determined by the history of known duration of the hypertension and the degree of variability of the blood pressure noted under our own observation. That is, the longer the history of hypertension as obtained from the patient and the less the variability of the blood pressure under our observation, the relatively shorter control period seemed necessary.

Both the sodium and potassium salts were used indiscriminately in our series and no record was kept of the particular salt administered to each individual patient. Such a record did not seem necessary in view of the evidence that the effective radical is the sulphocyanate only. In accordance with our stated intention of subjecting sulphocyanate therapy in hypertension to a severely strict evaluation we accepted as effective only such instances in which both systolic and diastolic blood pressures after treatment, fell to within or almost within the normal range. Furthermore it was insisted upon that the treated blood pressure must have fallen below the lowest of the control blood pressure readings within an average range of 45 mm. Hg. systolic and 31 mm. Hg. diastolic. In those instances in which we discontinued sulphocyanate before either a therapeutic or toxic effect occurred, the total amount which had been administered was with few exceptions greater than the amount frequently reported by others as an effective dosage.

In recent years a number of substances have been advocated as useful in artificially lowering the blood pressure in hypertension. Their effectiveness in this regard has not been generally confirmed. Sulphocyanate, on the other hand, has apparently met with approval among a large number of independent investigators. One fact seems true from our data; that is, that sulphocyanate will effectively lower blood pressure in one of about every three persons with hypertension. Our percentage of effectiveness (32.4%) is lower than that observed by many other investigators, probably because of our insistence upon the strict criteria of effect as stated. It seemed to us that only by adherence to such strict criteria could the effectiveness of sulphocyanate as a hypotensive drug be properly evaluated. Almost invariably fall in blood pressure was accompanied by subjective improvement. However subjective improvement occurred in many patients on sulphocyanate therapy, in whom no lowering of blood pressure occurred. This led us to believe that such improvement was largely psychic in nature Still, exclusive of toxic effects from the drug itself, no obvious harmful effects were noted from persistent lowering of a previously high blood pressure. Whether or not harmful effects occurred which were not immediately obvious, we cannot say from the data available.

In those individuals, in whom sulphocyanate was considered effective, the artificially lowered blood pressure returned to its previous level within 7 to 110 days. There was no constant relationship between the persistence of the hypotensive effect and the amount of sulphocyanate administered.

Where it is felt that sulphocyanate may be useful in a given patient the dose should not exceed 0.326 gm. (5 grains) daily. It is our expe-

rience that such daily dose may be effective in lowering blood pressure in as short a period as 14 days or it may be necessary to continue it as long as 78 days. At the first indication of toxic effect; fatigue, nausea and vomiting, or the first distinct fall in blood pressure, the drug should be discontinued. When the blood pressure, having responded by a satisfactory fall returns to its original high level, sulphocyanate may be safely readministered only when ferric chlorid added to the acidified urine indicates that the drug has been entirely excreted. If the blood pressure does not show a satisfactory fall after 26.16 gm. (5 grains daily for 80 days) have been taken, our data indicate that with few exceptions it is useless to continue the treatment.

The above scheme of dosage is purely arbitrary and based upon a consideration of our entire series as a group. However in considering individual patients, it must be concluded, that there is no constant dosage at which either toxic or therapeutic effects may be anticipated. Some of the inconsistencies observed are illustrated by the following: One patient who responded by fall in blood pressure on 3 successive occasions with 0.326 gm. (5 grains) daily subsequently failed to respond to a repetition of treatment with 0.326 gm. (5 grains) daily over a similar period of time. Another patient who responded by satisfactory fall in blood pressure on 0.326 gm. (5 grains) daily on 2 different occasions subsequently failed to respond to 0.652 (10 grains) daily given over a comparable period of time. A third patient who responded satisfactorily after a total dose of 13.2 gms. (202 grains), after complete elimination of the drug became severely toxic (hallucinations of sight and hearing, disorientation, etc.) on a subsequent total dose of 12.74 gms. (195 grains).

Our data lead us to believe that some individuals for reasons which are not clear, show a distinct susceptibility to sulphocyanate. This susceptibility manifests itself by certain symptoms of which the earliest are muscular weakness and nausea. It further appears from our observations that in certain individuals there is little or no margin of safety between the toxic and therapeutically effective dosage of sulphocyanate. At this time we know of no way of distinguishing those individuals who will exhibit susceptibility from those in whom the drug lowers blood pressure effectively without the development of toxic symptoms.

In an attempt to explain the occurrence of toxic phenomena, one is first concerned with the dosage used. It might be expected that toxic manifestations would occur only when the larger dosages were given. This is not so in the case of sulphocyanate. Severe toxic manifestations occurred in some individuals who had received less of the drug, both in total and average daily dosage, than others who developed no toxic signs.

Of the fifty patients with hypertension in this series, treated 74 different times with sulphocyanate, toxic manifestations occurred in thirteen. In eleven of these the toxic manifestations disappeared within a few hours to four days after discontinuance of the drug. The usual order in which the toxic symptoms made their appearance was as follows: muscular fatigue accompanied or followed by nausea; vomiting; disorientation and mental confusion; motor aphasia; hallucinations of sight and hearing, and in the two fatal cases progression to delirium; convulsive twitchings; coma and death.

Conclusions

Data are presented on 50 patients subjected to 74 different trials with sulphocyanate therapy. In 69 of these the hypertension was of the essential type and in the remaining 5, it was associated with chronic diffuse glomerulo-nephritis. Forty-four observations were made in the out-patient clinic and 30 with the patients confined to bed in the hospital.

Observations were made on the daily excretion rate of sulphocyanate in the urine and the number of days necessary for its complete elimination after continuous medication and after a single dose in patients with essential hypertension, nephritic hypertension and in normal persons. The slow excretion rate noted, indicated the marked tendency toward cumulation of the drug. This was most marked in the presence of glomerulo-nephritis.

Sulphocyanate was considered effective only when the blood pressure after treatment fell below the lowest reading of the control period within an average range of 45 mm. Hg. in the systolic and 31 mm. Hg. in the diastolic.

The dosage found to be the most effective in lowering blood pressure and least often attended by toxic manifestations, was 0.326 gm. (5 grains) given daily over a period of 14 to 78 days.

Thirteen patients showed toxic manifestations from sulphocyanate administered for therapeutic purposes.

Two of these patients died as a result of sulphocyanate poisoning. The order of appearance of the various toxic manifestations is noted.

Fall in blood pressure, occurrence of toxic manifestations, and death were found to be unrelated to the amount of residual drug in the body.

In some patients there is little or no margin of safety between the toxic and therapeutically effective dose of sulphocyanate.

Sulphocyanate effectively lowered the blood pressure in 32.4% of our series of 74 trials.

The incidence of toxic manifestations in this series was 17%.

RADIATION THERAPY OF RADICULITIS*

By LEE A. HADLEY, M.D., SYRACUSE, N. Y.

THE subject of radiculitis with its symptomatology and its association with spondylitis has been ably described by various authors in the English Literature. Results of its treatment by *X*-ray, however, have appeared almost entirely in the reports of European workers. It is then with the purpose of coordinating these that the following paper is presented.

Bechterew in 1893 and more recently Gunther and Kerr, Rosenheck, Mayer, Gordon, and others have mentioned the association of spinal arthritis with the radicular syndrome, i.e., a restricted mobility of the spine with motor or sensory alterations and root pains, aggravated by movement or coughing.

Neuralgic pains of this character may be of reflex origin; from systemic disease such as lues or anaemia; or from some local condition such as trauma, tumor or infection at any point of the tract from its origin downward. The most common pathology in cases of so-called radiculitis, however, seems to be a localized perineuritis at the foramen where the nerve leaves the cranium or spinal canal.

Gordon differentiates between radiculitis, i.e., inflammation of the nerve roots, and funiculitis or inflammation of that part of the nerve immediately beyond their junction: The roots are covered by the meninges and bathed in spinal fluid while the nerve is not. However, the clinical differentiation of these two is not readily made, the treatment is the same, and for the present consideration the term radiculitis will be used to include both conditions:

Anatomy and Pathology

Anatomically, the intervertebral foramen is bounded above and below by the pedicles of the adjacent neural arches, posteriorly by the superior and inferior articular processes and their interposed joint and anteriorly by the postero-lateral surface of the upper vertebral body, the intervertebral articulation, and to less extent the lower vertebral body. Above the level of the third lumbar occurs a strong ligament, not ordinarily described in the anatomies, crossing the intervertebral foramen dividing it into a small foramen below and a larger one above through which passes the nerve. Since this ligament extends from the lower part of the upper vertebral body to the superior articular process of the lower body it serves in the normal state to keep the nerve from coming directly in contact with the intervertebral articulation although of course the posterior articulation is in close relation to the nerve. Surrounding the nerve, within the foramen, are cellular tissue, lymphatics, the artery and a venous plexis, so that a congestive process, periostitis, inflammation or an osteophyte within this bony passage may cause radicular symptoms.

An early arthritic process may induce the localized neuritis or perineuritis of the intervertebral portion of the nerve, while chronic hypertrophic arthritis with spur formation may actually produce a narrowing of the lumen of its canal. Dorsal extension or lateral bending of the spine produces an encroachment upon the foramen by the superior articular process. Nathan as well as Bailey and Casamajor felt that the root symptoms were due to the mechanical irritation of pressure upon the nerve roots, but Parker and Adson who performed laminectomies on eight patients with nerve root and cord symptoms considered the process inflammatory with infection a common cause and trauma as a predisposing factor. This latter is the opinion of most writers on the subject. These authors also found that the hypertrophic bony process might be quite extensive without showing on the *x*-ray film.

This narrowing of the canal has been demonstrated by Nathan who produced a spondylitis experimentally in dogs by the injection of streptococci. This was characterized by hyperplastic changes about the joints, proliferation of connective tissue producing a nodular thickening of the periosteum, as well as organized epidural exudates within the intervertebral notches. These changes as well as the congested vertebral veins which he observed are said to correspond to the pathologic changes noted in spondylitis of man.

Clinical Picture

Most frequently encountered is that patient with midcervical radiculitis complaining of pain, aching or soreness, of the shoulder or arm. There may be a numbness or tingling of the fingers. Pressure of the arm, shoulder or along the course of the nerve is usually not painful. However, moderate pressure at different points along the two sides of the neck will elicit pain only over the corresponding nerve root. This is likely to be severe and constitutes a valuable diagnostic sign. The pain is usually aggravated by flexion or rotation of the cervical spine, hence the muscle spasm limiting spinal movements. It may be aggravated by sneezing, coughing, or increased intra-abdominal pressure, the so-called Dejerines sign which is said to be due to transmitted intraspinal pressure. This pain may be sharp or dull and occur in paroxysms or be constant. It seems to be influenced by weather, fatigue, exposure, toxemia, etc. Gunther and Kerr have demonstrated sensory changes to light touch. Muscle weakness and changed reflexes may also be present. When the condition is confined to the middle and lower

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 3, 1931.

cervical region it may be confused with bursitis or arthritis of the shoulder joint. In the absence of shoulder pathology, however, there is free passive movement of the arm and no tenderness upon deep pressure over the joint although the patient may complain of pain in the shoulder.

Pain is elicited upon deep pressure about one and one-half inches from the mid line of the back probably by the irritability of the corresponding spinal nerve roots, although tenderness of the posterior cutaneous nerve branches may be a factor. Discomfort is noted in the anterior chest when the patient bends or twists the back.

With involvement at different spinal levels the characteristic picture above described may vary somewhat. Upper cervical radiculitis produces occipital headache reaching upward to the vertex, frequently with painful palpable, nodules of increased tonicity in the muscles at the back of the neck. If the lesion is within the first five dorsal spaces, pain is complained of upon pressure between the scapulæ while the radicular distribution corresponds to the side of the chest and over the precordium. It is said that right-sided involvement is as frequent as left, but does not cause as much apprehension on the part of the patient. Intrathoracic diseases must be differentiated. Cases with severe pain down the left arm and anterior surface of chest probably constitute the so-called pseudo angina pectoris.

With radiculitis of the lower half of the dorsal and upper lumbar region the patient suffers abdominal distress, epigastric pain, burning, heaviness or gas pressure. Pain over the gall bladder, kidney, appendix or pelvic area may be complained of. These patients are the subjects of multiple, negative, laboratory tests and examinations. With pain referred to the ileoinguinal or ileohypogastric distribution they may be subjected to a cystoscopic and pyelographic examination. In search of relief for their pain, which is very real, they submit to multiple abdominal operations upon the appendix, pelvic organs, adhesions, etc., but they usually remain unrelieved and are finally labeled neurotics.

Carnett, in attempting to explain the 40% of failures to relieve chronic lower abdominal pain by appendectomy, concludes that this pain is often parietal, due to intercostal neuralgia and independent of any intraabdominal lesion. He states, "In my experience nearly all the patients who have multiple abdominal scars and are still complaining of abdominal pain and tenderness present definite signs of intercostal neuralgia." This author states that voluntary tensing of the muscles in the abdominal wall protects the intra-abdominal organs from palpatory pressure. So that, if the abdominal pain is still present when the patient raises the head or extended legs from the table it may be assumed as parietal, originating in the abdominal wall and will be associated with a tenderness of the corresponding intervertebral spaces.

With arthritis of the upper lumbar region the patient may complain of a burning pain on the lateral surface of the thigh corresponding to the distribution of the lateral cutaneous nerve. This symptom, the so-called meralgia paresthetica is considered by Rosenheck in a report of twenty-five cases as of radicular origin secondary to the arthritis.

And finally, involvement of the lower lumbar and first two sacral segments may produce pain over the gluteal region, the back of the leg, and especially the outer side of the lower leg if the fifth root is involved, a clinical picture which may be confused with sciatica. The nerve is not usually painful to deep pressure. Danforth and Wilson from studies of twelve anatomical specimens and twenty-one clinical cases conclude that the pain particularly with disturbance of the Achilles tendon reflex is a symptom or arthritic change at the lumbo-sacral junction or the inter vertebral canal between the fourth and fifth lumbar vertebrae. Arthritis of the sacro-iliac joints does not seem to be a factor in this condition. These writers also observed a definite tightening of the third, fourth, and fifth lumbar roots when the thigh was flexed with the knee extended. Hyperextension of the thigh or flexion of the knee appeared to relax these nerve roots.

There may be a progressive involvement with remissions or with different spinal root areas attacked at different times, the condition being one of considerable chronicity.

Protective muscle spasm may cause the patient more discomfort than the primary lesion and manifests itself as a myalgia of the neck or back muscles.

Treatment

Therapy is carried out along three lines: relief of symptoms, prevention, and treatment of the underlying pathology. For symptomatic relief, rest, sedatives, and heat in some form, diathermy, infra-red, therapy light or baking followed by massage to relax the muscle spasm are indicated. Strapping the back may afford additional relief. Prevention of recurrent attacks may be favored to some degree by wearing a supporting belt or jacket, or the development of an increased muscular tone and proper posture by corrective exercises.

The greatest measure of relief, however, is afforded by the use of radiation therapy applied to the nerve roots. While the *x*-ray cannot influence the bony changes that have already taken place, different authors state that it is able to produce an absorption of the localized inflammatory process about the nerve at the spinal foramen. Babinski in 1908 was the first to report the attenuation of neuralgic pain due to spondylitis by means of *x*-ray therapy, although the analgesic effect of

x-ray obtained in trigeminal neuralgia had been reported by Gocht as early as 1897. Carter, Richards, Del Buono, Walter and Cottenot also treated Tic Doulereux with good results providing surgery or alcohol injection had not been previously used. Following these therapeutic measures, however, radiation was not as efficacious and therefore should be used first since it is less radical and produces relief in about seventy-five per cent of the cases.

Mode of Action

The pain is said to be due to compression of the nerve by inflammatory swelling within the unyielding bony canal and may be temporarily aggravated for a few hours following the x-ray treatment; this however, is considered a favorable prognostic sign. Different authors state that the young radiosensitive cells of the inflammatory infiltration are destroyed by the radiation with a resulting decompression and disappearance of the pain. The younger cells are extremely radiosensitive which explains the superior results achieved in recent cases and by the use of only small doses of x-ray.

There seems to be general agreement as to the value of the method, the dosage, and the percentage of patients relieved, and while most authors state that the effect of the ray is upon the inflammatory cells other theories have been advanced to explain the clinical results observed. Langer, also Delherm and Beau believe that the effect is upon the sympathetic system, while Leonard and Desjardins feel that there is some specific analgesic action upon the nerve cells which are ordinarily resistant to x-ray. Phillips explains the effect by assuming that x-ray can stimulate the metabolic processes of the nerves. Hesnard and Pfender believe that connective tissue surrounding the nerve is softened while Boner, speaking of the effect of x-ray upon inflammatory conditions, explains that effect by the dynamic property of radiant energy.

There is a paucity of experimental evidence to explain the results observed. Schaefer, Businco and Motojima hastened the absorption of acute inflammatory reactions in experimental animals by x-ray while Maximo and Hesnard produced softening of chronic inflammatory tissue by this means. The latter treated eighty French war-wounded having nerves involved by scar tissue; of these, eighteen were completely cured and fifty more partially relieved. He then undertook animal experimentation and discovered that scar tissue subjected to x-ray became softened and that the incarcerated nerve after treatment could be readily separated by blunt dissection much the same as a normal nerve in a clean field. This was in marked contrast to the control scars involving nerves and not so treated. He also noted lessened infiltration following the radiation.

Technique

Both Heidenhain and Holzknecht urge the use of small doses at intervals of four to six days for a month if necessary. The radiation is applied to the nerve roots, not to the areas of pain distribution. If there is a complicating neuritis it may occasionally be necessary to radiate the peripheral nerve. A fairly high voltage with ample filtration is recommended. Improvement is usually noted about seven to ten days after instituting treatment, but may appear as early as twelve hours.

Results of X-ray Therapy

As previously stated most of the serial reports have come from European Clinics. Stembo in 1900 reported twenty-eight cases of neuralgia treated with x-ray of which seventy-five per cent were cured. Barre and Gunsett treated twenty cases with sixty per cent relieved and fifteen per cent improved. Cottenot treated one hundred and eight cases with almost identically the same percentages. Other than chronicity there has apparently been no explanation offered to account for the fifteen per cent failures that appear in nearly all reports. Recent Advances in Neurology for 1930 states as follows: "X-ray not only removes the neuralgic pain but also removes its cause by freeing the involved nerve roots from the pressure exerted by obstructed veins, connective tissue or swollen periostium. The results of this radiation are brilliant. The more recent the inflammation, the more sensitive the tissue and the more rapid the success of the treatment."

Personal Observations

The writer has treated 83 cases of which 70% were relieved, 24% partially relieved, and 6% received no benefit whatever.

Certain patients had more than one area involved. There were 53 cervical, 22 dorsal, 22 lumbar, 7 facial, and 2 trigeminal. Each patient received an average of 3.36 x-ray treatments, the number ranging from 1 to 10. 61 patients received diathermy and 49 massage in addition to x-ray. These improved more rapidly than those receiving x-ray only, although one of the cases of facial neuritis had not responded to heat treatment alone, but began to improve promptly following x-ray. Duration of symptoms varied from 2 days to 15 years, those of longer duration being more resistant to treatment.

One patient receiving 10 treatments was not benefited the condition being post-traumatic following an auto accident two months before. Another patient with trigeminal involvement was only partially relieved by 4 treatments. Hormone dysfunction was probably a factor since at repeated pregnancies she was entirely free of symptoms throughout the period of gestation. One patient only partially benefited was markedly anaemic.

cervical region it may be confused with bursitis or arthritis of the shoulder joint. In the absence of shoulder pathology, however, there is free passive movement of the arm and no tenderness upon deep pressure over the joint although the patient may complain of pain in the shoulder.

Pain is elicited upon deep pressure about one and one-half inches from the mid line of the back probably by the irritability of the corresponding spinal nerve roots, although tenderness of the posterior cutaneous nerve branches may be a factor. Discomfort is noted in the anterior chest when the patient bends or twists the back.

With involvement at different spinal levels the characteristic picture above described may vary somewhat. Upper cervical radiculitis produces occipital headache reaching upward to the vertex, frequently with painful palpable, nodules of increased tonicity in the muscles at the back of the neck. If the lesion is within the first five dorsal spaces, pain is complained of upon pressure between the scapulæ while the radicular distribution corresponds to the side of the chest and over the precordium. It is said that right-sided involvement is as frequent as left, but does not cause as much apprehension on the part of the patient. Intrathoracic diseases must be differentiated. Cases with severe pain down the left arm and anterior surface of chest probably constitute the so-called pseudo angina pectoris.

With radiculitis of the lower half of the dorsal and upper lumbar region the patient suffers abdominal distress, epigastric pain, burning, heaviness or gas pressure. Pain over the gall bladder, kidney, appendix or pelvic area may be complained of. These patients are the subjects of multiple, negative, laboratory tests and examinations. With pain referred to the ileoinguinal or ileohypogastric distribution they may be subjected to a cystoscopic and pyelographic examination. In search of relief for their pain, which is very real, they submit to multiple abdominal operations upon the appendix, pelvic organs, adhesions, etc., but they usually remain unrelieved and are finally labeled neurotics.

Carnett, in attempting to explain the 40% of failures to relieve chronic lower abdominal pain by appendectomy, concludes that this pain is often parietal, due to intercostal neuralgia and independent of any intraabdominal lesion. He states, "In my experience nearly all the patients who have multiple abdominal scars and are still complaining of abdominal pain and tenderness present definite signs of intercostal neuralgia." This author states that voluntary tensing of the muscles in the abdominal wall protects the intra-abdominal organs from palpatory pressure. So that, if the abdominal pain is still present when the patient raises the head or extended legs from the table it may be assumed as parietal, originating in the abdominal wall and will be associated with a tenderness of the corresponding intervertebral spaces.

With arthritis of the upper lumbar region the patient may complain of a burning pain on the lateral surface of the thigh corresponding to the distribution of the lateral cutaneous nerve. This symptom, the so-called meralgia paresthetica is considered by Rosenheck in a report of twenty-five cases as of radicular origin secondary to the arthritis.

And finally, involvement of the lower lumbar and first two sacral segments may produce pain over the gluteal region, the back of the leg, and especially the outer side of the lower leg if the fifth root is involved, a clinical picture which may be confused with sciatica. The nerve is not usually painful to deep pressure. Danforth and Wilson from studies of twelve anatomical specimens and twenty-one clinical cases conclude that the pain particularly with disturbance of the Achilles tendon reflex is a symptom or arthritic change at the lumbo-sacral junction or the intervertebral canal between the fourth and fifth lumbar vertebrae. Arthritis of the sacro-iliac joints does not seem to be a factor in this condition. These writers also observed a definite tightening of the third, fourth, and fifth lumbar roots when the thigh was flexed with the knee extended. Hyperextension of the thigh or flexion of the knee appeared to relax these nerve roots.

There may be a progressive involvement with remissions or with different spinal root areas attacked at different times, the condition being one of considerable chronicity.

Protective muscle spasm may cause the patient more discomfort than the primary lesion and manifests itself as a myalgia of the neck or back muscles.

Treatment

Therapy is carried out along three lines: relief of symptoms, prevention, and treatment of the underlying pathology. For symptomatic relief, rest, sedatives, and heat in some form, diathermy, infra-red, therapy light or baking followed by massage to relax the muscle spasm are indicated. Strapping the back may afford additional relief. Prevention of recurrent attacks may be favored to some degree by wearing a supporting belt or jacket, or the development of an increased muscular tone and proper posture by corrective exercises.

The greatest measure of relief, however, is afforded by the use of radiation therapy applied to the nerve roots. While the *x*-ray cannot influence the bony changes that have already taken place, different authors state that it is able to produce an absorption of the localized inflammatory process about the nerve at the spinal foramen. Babinski in 1908 was the first to report the attenuation of neuralgic pain due to spondylitis by means of *x*-ray therapy, although the analgesic effect of

x-ray obtained in trigeminal neuralgia had been reported by Gocht as early as 1897. Carter, Richards, Del Buono, Walter and Cottenot also treated Tic Doulereux with good results providing surgery or alcohol injection had not been previously used. Following these therapeutic measures, however, radiation was not as efficacious and therefore should be used first since it is less radical and produces relief in about seventy-five per cent of the cases.

Mode of Action

The pain is said to be due to compression of the nerve by inflammatory swelling within the unyielding bony canal and may be temporarily aggravated for a few hours following the *x*-ray treatment; this however, is considered a favorable prognostic sign. Different authors state that the young radiosensitive cells of the inflammatory infiltration are destroyed by the radiation with a resulting decompression and disappearance of the pain. The younger cells are extremely radiosensitive which explains the superior results achieved in recent cases and by the use of only small doses of *x*-ray.

There seems to be general agreement as to the value of the method, the dosage, and the percentage of patients relieved, and while most authors state that the effect of the ray is upon the inflammatory cells other theories have been advanced to explain the clinical results observed. Langer, also Delherm and Beau believe that the effect is upon the sympathetic system, while Leonard and Desjardins feel that there is some specific analgesic action upon the nerve cells which are ordinarily resistant to *x*-ray. Phillips explains the effect by assuming that *x*-ray can stimulate the metabolic processes of the nerves. Hesnard and Pfender believe that connective tissue surrounding the nerve is softened while Boner, speaking of the effect of *x*-ray upon inflammatory conditions, explains that effect by the dynamic property of radiant energy.

There is a paucity of experimental evidence to explain the results observed. Schaefer, Businco and Motojima hastened the absorption of acute inflammatory reactions in experimental animals by *x*-ray while Maximo and Hesnard produced softening of chronic inflammatory tissue by this means. The latter treated eighty French warwounded having nerves involved by scar tissue; of these, eighteen were completely cured and fifty more partially relieved. He then undertook animal experimentation and discovered that scar tissue subjected to *x*-ray became softened and that the incarcerated nerve after treatment could be readily separated by blunt dissection much the same as a normal nerve in a clean field. This was in marked contrast to the control scars involving nerves and not so treated. He also noted lessened infiltration following the radiation.

Technique

Both Heidenhain and Holzknecht urge the use of small doses at intervals of four to six days for a month if necessary. The radiation is applied to the nerve roots, not to the areas of pain distribution. If there is a complicating neuritis it may occasionally be necessary to radiate the peripheral nerve. A fairly high voltage with ample filtration is recommended. Improvement is usually noted about seven to ten days after instituting treatment, but may appear as early as twelve hours.

Results of *X*-ray Therapy

As previously stated most of the serial reports have come from European Clinics. Stembo in 1900 reported twenty-eight cases of neuralgia treated with *x*-ray of which seventy-five per cent were cured. Barre and Gunsett treated twenty cases with sixty per cent relieved and fifteen per cent improved. Cottenot treated one hundred and eight cases with almost identically the same percentages. Other than chronicity there has apparently been no explanation offered to account for the fifteen per cent failures that appear in nearly all reports. Recent Advances in Neurology for 1930 states as follows: "*X*-ray not only removes the neuralgic pain but also removes its cause by freeing the involved nerve roots from the pressure exerted by obstructed veins, connective tissue or swollen periostium. Personal Observations

The writer has treated 83 cases of which 70% were relieved, 24% partially relieved, and 6% received no benefit whatever.

Certain patients had more than one area involved. There were 53 cervical, 22 dorsal, 22 lumbar, 7 facial, and 2 trigeminal. Each patient received an average of 3.36 *x*-ray treatments, the number ranging from 1 to 10. 61 patients received diathermy and 49 massage in addition to *x*-ray. These improved more rapidly than those receiving *x*-ray only, although one of the cases of facial neuritis had not responded to heat treatment alone, but began to improve promptly following *x*-ray. Duration of symptoms varied from 2 days to 15 years, those of longer duration being more resistant to treatment.

One patient receiving 10 treatments was not benefited the condition being post-traumatic following an auto accident two months before. Another patient with trigeminal involvement was only partially relieved by 4 treatments. Hormone dysfunction was probably a factor since at repeated pregnancies she was entirely free of symptoms throughout the period of gestation. One patient only partially benefited was markedly anaemic.

Four patients returned for treatment of recurrence. *X*-ray in each case revealed advanced arthritic changes in the spine. Three of them had both dorsal and cervical involvement at different times. Those having definite *X*-ray evidence of arthritis were somewhat more resistant to treatment and the result in 5 of the 14 cases was not entirely satisfactory. Two of these patients were men with lumbar involvement and did not improve until spinal support was supplied.

On nervous patient with an extensive scar following chemical removal of the breast received little benefit from 8 treatments. Her pain may have been partially reflex in origin.

Another patient complaining of sciatica of six months duration whose *x*-ray showed a lumbosacral arthritis was temporarily relieved by three treatments, but later developed a malignant tumor of the corresponding ishium.

In certain cases the patient's pain was worse the day after treatment. This temporary aggravation, however, was always followed by improvement.

Conclusions: Radiculitis, usually associated with spondylitis, is characterized by pain in those peripheral areas supplied by the corresponding nerve roots, aggravated by coughing, sneezing, or twisting the back, and reveals tenderness to deep pressure along the spine. This condition is frequently relieved by fractional doses of *x*-ray applied to the nerve roots.

The treatment may well be supplemented by diathermy, rest, and support.

Factors apparently limiting the effectiveness of the treatment are: Advanced arthritis, anaemia, and continued toxic absorption.

There is no contraindication to radiation therapy in the small dosage used.

EXOPHTHALMIC GOITRE IN CHILDREN*

By GEORGE E BEILBY, M D, AND JAMES G CARLTON, M D, ALBANY, N Y

EXOPHTHALMIC goitre in children has always occasioned particular interest, both because of its comparative rarity and from the peculiar problems that naturally arise in its treatment Our interest was recently directed anew to this question by a case of true exophthalmic goitre in a child two years and nine months of age It seemed to us in reporting cases of goitre in children and reviewing the literature there should be a clear definition, first, as to the type of goitre considered, and, second, the age period in which the cases fall Because the development of children varies so greatly with age, it seemed proper to include only cases arising before puberty in the childhood group, and therefore in this report only such cases have been included We have not taken into consideration cases of adolescent goitre or colloid goitre with mild hyperthyroidism but only cases of exophthalmic goitre which have come to operation and in which the diagnosis has not only been proven clinically but by pathological report

In our own clinic in a series of 1,600 cases we have had five cases of exophthalmic goitre before puberty Their respective ages were one case two years and nine months, one case nine years, two cases eleven years, one case thirteen years The youngest child in this group was of particular interest because of the rarity of the disease at this age In reviewing the literature we were able to find only eight cases of exophthalmic goitre in children under five years of age Six of these cases only were three years of age or under Our own case therefore seemed of sufficient interest to place on record and at the same time to report briefly the other four cases occurring before puberty

While exophthalmic goitre is rare under five years of age it cannot be considered at all unusual under fifteen years of age or during the adolescent period We have had a considerable number of cases under fifteen years of age Most of these occurred between ten and fifteen years The eight cases five years of age or under found in the literature or by personal communications were as follows

Mayo Clinic[1]—Two cases, one five and one three years

Lahey Clinic[2]—One case, three years

DeWitt Sherman,[3] Buffalo—One case, two and one half years

Baird[4] of London—One case, two and one-half years

Barrett[5]—One case, two and one-half years

Klaus[6]—One case in infant nine months old

Schkarin[7]—One case, four and one-half years old

A report of the five cases which form the basis of this study follows

Case 1—J S Female Age Two Years, Nine Months

First seen January 27, 1931 Both parents living and well No history of goitre in the family For the past year the mother had noticed that the child's heart beat very rapidly and forcefully About the same time she also noticed that the child seemed to be shaky, and if she became excited would frequently drop anything she might have in her hand She was ravenously hungry all the time and very active There was no dyspnea She had great difficulty in keeping the child covered at night Previous to this illness the child had always been well She had had none of the usual diseases of childhood She was a normal full-term child, weighing 8 lbs 9 oz at birth, breast fed for six months, and her development was normal At about the age of two years two months the mother thought the eyes were staring She gradually became more nervous and irritable and her appetite seemed to increase She did not gain weight No medical advice was sought for about six months, at which time there was marked exophthalmos and on calling the family physician she was promptly referred to our clinic She was admitted to the Albany Hospital January 31, 1931

Physical Examination On admission the child weighed 32 lbs, rectal temperature 99 degrees F Pulse 130, respiration 24 She was well

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, July 2, 1931

nourished and well developed but very hyperactive. Skin was warm and moist. There was a tremor of all extremities. Exophthalmos was marked. Von Graefe, Stellwag and Moebius signs were all present. There was no nystagmus. Pupils reacted normally to light and accommodation. Eye grounds were negative. Examination of nose and ears was negative. There was a fine tremor of the tongue. Teeth were in fairly good condition. Tonsils were hypertrophied and cryptic. Tonsil glands were palpable. There was a diffuse, rather firm enlargement of the thyroid gland. Trachea was in the mid line and there was no evidence of pressure. There was a marked bruit over the gland but no thrill. Examination of the thorax showed a symmetrical development with expansion equal. Percussion and auscultation were normal. There was no widening of the upper mediastium. The heart was moderately enlarged to the left. A systolic murmur was heard over the precordium. The abdomen was negative. Blood pressure systolic 100, diastolic 0.

Laboratory Findings: Urine showed specific gravity of 1015, reaction acid, trace of albumin, sugar negative. Microscopic examination negative. Blood count showed, R.B.C. 4,950,000; W.B.C. 14,400. Differential count—polymorphonuclears, 35%; small mononuclears, 57%; large mononuclears, 7%; basophils, 1%. Several attempts to get a basal metabolism rate were unsuccessful. Finally a fairly satisfactory rate of plus 94 was obtained.

X-ray examination of the chest showed cardiac enlargement measuring 8.5 cm. in the greatest transverse diameter. Lungs were negative. There was no evidence of an enlarged thymus. *X*-ray of the skull was negative. In the preoperative period the pulse ranged from 110 to 150, averaging about 130. The rectal temperature averaged about 100 degrees F. Respirations normal. The child was very hyperactive and slept poorly. She was given luminol, grs. ½, every night for one week. On February 5th she was given Lugol's Solution, mm. 2, T.I.D. She was kept in bed with a high caloric diet and high fluid intake. On February 10th Lugol's solution was increased to M. 5, T.I.D., and she was allowed to be out of bed for a short time each day. Her nervousness decreased and she was not as hyperactive. She also began to gain weight. On February 18th her temperature rose to 101 F. and on the 19th to 102 F. At this time we could find no reason for the elevation. On the 20th her temperature was down but on the 21st was again elevated and the left ear drum was reddened. On the 22nd her temperature was 104 F. and the drum was edematous and bulging. A myringotomy was performed under very light ether anesthesia. Drainage was profuse and temperature returned to normal. On the 24th the same condition developed in the right ear and this likewise had to be opened. On the 27th her temperature had returned to normal. At this time she had lost all the weight she had gained. On March 1st Lugol's Solution was increased to M. 10, T.I.D., and on March 10th her pulse was ranging from 100 to 120, and we felt that we had obtained the maximum benefit that could be derived from treatment, and therefore on March 12th a bilateral subtotal thyroidectomy was performed under ether anesthesia. The operation was done in the usual manner and about the same amount of thyroid tissue removed as in an adult case. During the operation her pulse ranged from 100 to 128—it was regular and of good quality. The entire operation required 24 minutes and 1½ oz. of ether were used. Post-operative reaction was not severe, pulse ranging from 130 to 150 and rectal temperature from 100 to 102.

Pathological Report—Gross: Thyroid tissue in two portions of about equal size, and together weighing 17 gms. The portions are similar in appearance, each being partially covered by a thin fibrous capsule. The tissue appears dark red and meaty. One portion measures 5 x 2.5 x 1.7 cm. and the other 5 x 2.5 x 2.3 cms. The tissue is roughly lobulated. The cut surface appears to be finely lobulated, rather granular, and of a grayish-red color. Small colloid droplets can be seen. Fibrous septa incompletely divide the tissue into lobules of various sizes. There are no cysts, hemorrhages, areas of degeneration, or discrete adenomatous nodules.

Microscopic: Exophthalmic goitre.

The child was up and about the ward in a week and continued to improve satisfactorily and returned home in about three weeks after the operation. Up to the present time improvement has been steady. All symptoms have disappeared. On March 31st basal metabolic rate of plus 19 was obtained. We have not been able to obtain a satisfactory reading since that time.

Case 2—L. M. Age Nine. Female

First seen April, 1922. There was nothing of importance in the family histary. During the seven months preceding the mother had noticel a gradual increase in the size of her neck and that the child was becoming more nervous. She perspired freely and lost weight in spite of a ravenous appetite.

Physical Examination: Well developed, well nourished child, very nervous and hyperactive. Skin was moist. Slight exophthalmos present. Bilateral symmetrical enlargement of thyroid gland. Heart very rapid. Lungs negative—abdomen negative. Blood pressure 120/30.

Laboratory Findings: Urine negative. Basal metabolism plus 51. Preoperative treatment consisted of rest in bed, high caloric diet and high

fluid intake On the third day bilateral subtotal thyroidectomy was performed Post operative reaction was not severe and she was discharged from the hospital the 8th day after operation Microscopical examination confirmed pre operative diagnosis of exophthalmic goitre The child remained well and up to the present time has had no return of symptoms

Pathological Report—Microscopic Hyperplastic thyroid

CASE 3—M. L AGE ELEVEN FEMALE

First seen October, 1929 Mother first noticed swelling in the anterior part of neck two years previous At that time she was given a little iodine which seemed to help her and decrease the swelling About six weeks ago the patient began to lose weight and have slight muscular incoordination She perspired freely and tired very easily Her appetite increased in the last month History otherwise negative

Physical Examination Child well nourished and well developed Skin warm and moist Eyes slightly staring Thyroid gland shows a symmetrical enlargement, rather firm and of moderate degree Heart—slight enlargement to the left Rate, 120 to 130 Lungs, negative Abdomen, negative All tendon reflexes were hyperactive

Laboratory Findings Urine, negative Blood count, normal Basal metabolism plus 41 Pre operative treatment consisted of Lugol's Solution, rest in bed, high caloric diet, increased fluid intake and several hours each day in the open air On the 12th day after admission a bilateral subtotal thyroidectomy was performed Post operative reaction was not severe and the child was discharged on the eleventh day after operation This patient had no return of her symptoms at all and was well until December, 1930, at which time the mother thought she showed some of her former symptoms On examination we find some evidence of a recurrence of the hypertrophy Basal metabolism showed a rate of plus 20 This child is being kept under observation and it is quite possible that a second operation may be necessary

Pathological Report—Gross Hemorrhagic, glandular tissue External surface is covered partially by a smooth membrane On section tissue is firm and slightly edematous

Microscopic Hyperplastic thyroid gland with considerable colloid

CASE 4—M K AGE THIRTEEN FEMALE

First seen in August, 1929 Well developed and well nourished girl, with rather marked exophthalmos Family history negative Patient had always been well until June, 1929, when she had a dry nonproductive cough and began to sleep poorly Soon after this she began to lose weight, and her mother noticed that she was very nervous There has been a tremor of her hands, excessive perspiration, and increased appetite Her eyes have become more prominent for the last six weeks

Physical Examination Well developed and well nourished female child, very hyperactive Skin warm and moist Moderate exophthalmos Von Graefe, Stellwag and Moebius signs were present Ears, teeth, nose and throat negative There was a firm symmetrical hypertrophy of both lobes of the thyroid and the isthmus Examination of chest and lungs negative Heart was not enlarged Soft systolic murmur heard over the entire precordium—rate very rapid—abdomen negative Extremities—fine tremor of fingers Tendon reflexes were all hyperactive Blood pressure 140/60

Laboratory Findings Blood count, hemoglobin, 85%, R B C, 4,500,000, W B C, 9,000 Clotting time, 2 minutes, 20 seconds Urine, negative Basal metabolism, plus 55 Pre operative treatment consisted of Lugol's Solution M 10 T I D, rest in bed, fresh air, high caloric diet and high fluid intake On admission pulse rate was 140 Under treatment this came down to between 90 and 100 in nine days On the tenth day a bilateral subtotal thyroidectomy was performed She had a very quiet convalescence and was discharged on the 12th day after operation This patient has remained well and has had no return of symptoms Her exophthalmos also improved

Pathological Report—Microscopic Exophthalmic goitre

CASE 5—M P AGE ELEVEN FEMALE

First seen in November, 1925, complaining of nervousness Family history negative For the past three years there has been a slight swelling in her neck During the past year this has increased in size She has lost weight, sleeps poorly, and is irritable and has a tremor of her hands

Physical Examination Well developed and well nourished girl, very restless and irritable Skin warm and moist Eyes prominent Von Graefe, Stellwag and Moebius signs present Ears and nose negative Thyroid gland shows a firm, bilateral smooth hypertrophy Chest and lungs negative, heart slightly enlarged to the left Sounds snapping with systolic murmur over the precordium Pre operative treatment, rest in bed, high caloric diet, high fluid intake, Lugol's, M 10, T I D A bilateral subtotal thyroidectomy was performed on the 10th day There was a moderately severe post operative reaction Patient was discharged on the seventh day after

operation. She has been in good health and has developed normally up to the present time.

Pathological Report—Microscopic: Diffuse, moderately hyperplastic thyroid with lessened colloid and pronounced acinar, hyperplasia and some epithelial metaplasia.

It will be seen, therefore, that primary hyperthyroidism or exophthalmic goitre in children differs in no way in its symptomatology and course from the disease in adults. The thyroid gland shows the same characteristic enlargement. Exophthalmos, tachycardia, tremor, hyperactivity, irritability and nervousness with increased appetite and weight loss are present in the same manner and to a degree proportionat to the severity of the intoxication, just as we find it in the adult patient.

The diagnosis of the disease is not difficult in children; in fact, all of the symptoms stand out more prominently in the youthful patient. Because the disease is apt to progress rapidly in children early recognition is extremely desirable before serious complications develop.

In approaching so serious a disease as exophthalmic goitre in childhood we have always had a feeling of extreme caution and conservatism. In our early experience with these cases we had little to guide us. Very few cases had been reported under puberty—and many questions and doubts naturally arose in our minds. Usually every method of treatment had been tried, without success, before the case had come into our hands. We were therefore left with no alternative but an operation. A determination had to be made of the best method of procedure—whether single or multiple stage operation was best suited to patients of this age. Our experience with primary goitre in children under puberty has not been great in point of numbers, but these five cases operated upon and followed, some of them for eight to ten years during their periods of adolescence and development, have given us an opportunity to formulate some rather definite conclusions.

First, as to the operation itself—it is my belief that the same principles should guide us as in the handling of the adult case. I think it might be said that after a long period of hospitalization (and I believe these cases should have a longer period as a rule than an adult) we are practically free from one serious element which contributes to the operative risk, and that is fear on the mental state. I think it is recognized by all operators that fear contributes greatly in adults to the operative risk. This has been one great advantage of the lengthening the pre-operative preparatory period, made necessary by the administration of Lugol's Solution for ten days or two weeks before operation. These patients become acclimated, so to speak, gain confidence and largely lose the fear of an operation which they almost all have on admission to a hospital. Since the advent of Lugol's Solution in the preparation of toxic as well as primary goitre cases we have had no severe post-operative crises in these young patients. The complete operation has been done in every instance. In fact my personal feeling is that multiple operations are very rarely necessary, either in children or adults, where a sufficient time is given for preparation. I believe, where one is in doubt, it is better to add a week or two or even more to the preparation than it is to do an incomplete operation and require a patient to submit to a second or a third operation in a few weeks or months. I have always felt that where a part of a hyperactive gland is left following an operation that the post-operative reaction is more severe than where the complete operation is done. The added time required is usually but a few minutes and is more than compensated for by completely ridding a patient of a hyperfunctioning gland. The only exception I think should be where some serious complication arises during the operation which necessitates a rapid termination of any further operative procedure for the time being.

Another important problem in connection with subtotal thyroidectomy in children is the amount of gland tissue that should be removed. I think if we are to obtain as high a percentage of cures as we do in adult patients, we must be guided by about the same principles. Realizing the important role which the thyroid gland plays in the physical and mental development of children we have always been somewhat more conservative and left behind slightly larger amounts of the gland than is our practice in adults. We can better take the risk of a second operation than to deprive a growing child of needed thyroid function. Experience may teach us that thyroid tissue regenerates more readily in the young individual and that we can safely remove an amount at least proportionate to the older patient. In the five cases which we have reported, three of them have remained well, with no evidence of recurrence for periods of two to nine years. Development has been normal. One case operated upon two years ago has a slight recurrence. The fifth case is of too recent date to determine the final outcome.

Annual meeting Buffalo, May 23 25, 1932

MEDICAL SERVICE

The immediate problem before the medical profession of the State of New York is that of an increased participation of the State in giving medical service to the people Medical service consists not merely in the professional assistance rendered by the family doctor and the consultant It also consists in providing the means for applying that service, such as hospitals, laboratories, public health nursing and social service These accessory services are needed not only by the indigent but often by those of moderate financial means, and even by the rich in emergencies These services do not conflict with the private practice of medicine but they are welcomed by doctors generally They are the subject of constructive investigation by the Joint Committee which is considering the report of the Governor's Health Commission

AMERICAN COLLEGE OF SURGEONS

The Clinical Congress of the American College of Surgeons held in New York City and Brooklyn during the week beginning October 12, was an outstanding event in American medicine. This was the annual meeting of the College, and was attended by over 2,900 leaders in that half of medical practice called surgery. The headquarters of the College, the principal meetings, and the exhibits were held in the new Waldorf-Astoria Hotel, which housed the Congress comfortably. The Grand Ball Room with its spacious corridors and its connecting rooms were fully occupied with the meeting, the exhibits and the demonstrators.

The Congress was composed of three distinct features:

1. The clinics.
2. The exhibits.
3. The meetings.

The very name of the Congress emphasized its *clinical* feature, for the daily practice of a surgeon is largely in hospital operating rooms and wards. The great magnet that draws surgeons together is the opportunity to see the routine activities of the several hospitals of a great city, in which work of the highest standard is exemplified.

Teaching clinics were held daily and almost hourly, in practically every hospital in Greater New York. Even those in Nassau County, adjoining the city on the East, were included as illustrations of the high class of surgical work done by the rank and file of surgeons, in distinction from those of wide fame in the large cities. It is in hospitals of the smaller communities that the majority of surgeons are working; and the results attained in them are equal to those of the teaching hospitals of the great cities, as is attested by the admission of these surgeons as welcome members of the College.

Simply to enumerate the hospitals and clinics required about thirty feet of column space in the announcement; and the amount of information dispensed was encyclopedic.

The collection of exhibits was the feature which first struck the eye of the visitor at the headquarters. These exhibits were both scientific and commercial; but scientific information was emphasized at the commercial booths as well as those devoted to purely scientific demonstrations.

Of special interest were the numerous pieces of apparatus used in treating fractures of bones and dislocations of joints. An intensive study of this part of the exhibit for half a day would well repay any doctor who does emergency work in either the city or the isolated community.

The scientific meetings were open to all physicians, and the addresses were front page news to the metropolitan daily papers. Every morning paper of the better class gave at least half a page to the proceedings of the Congress, and reported the addresses with remarkable wisdom and restraint. Every business man took an interest in the Congress to such an extent that his usual greeting of a doctor friend was "I suppose you are on your way to the medical convention."

The crowning event of the sessions was the meeting on Friday evening when new members were initiated into the College with an impressive ritual and ceremony.

The annual Congress is a prelude and inspiration to its major work which is carried on by the members throughout the year, as they perform their daily tasks in accordance with the high standards which they themselves have voluntarily adopted. Two of those standards apply to hospitals. In order that a hospital may receive the approval of the College, the members of the staff must—

1. Hold regular meetings at least once a month at which all cases of death are reported and discussed.
2. The history of every patient shall be written in full form, so that anyone reading it may get a clear picture of the sickness.

These standards are great incentives to good work, both surgical and medical, for the record of every doctor affects all the other members of the staff. Developing a consciousness of these standards in the minds of all doctors is perhaps the most outstanding accomplishment of the College.

The Medical Society of the State of New York was honored by the election of its President-elect, Dr. Charles Gordon Heyd, as Vice-President-elect of the College.

THE FAMILY DOCTOR

No one need to be told to consult a doctor in the presence of severe pain or a crippling condition; but when the immediate crisis is over, both the patient and the doctor are usually willing to end their professional relations.

A family doctor is the medical advisor in health as well as in sickness; but the doctor hesitates to impose his advice unasked, for ignorance and financial economy deter the people from seeking medical advice between periods of acute sickness.

A typical example of the need for so-called preventive advice is that of a child who has recurring attacks of mild disturbances, either respiratory or digestive The doctor calls only during the attacks, and gets credit for the relief which would have come spontaneously anyhow Here are two distinct conditions

1 The acute attack

2 The underlying cause or susceptibility

People are not accustomed to submit to the inconvenience and expense of securing a diagnosis of the underlying cause of the attacks

A family doctor is not accustomed to study the patients in the intervals between the attacks. Possibly the examinations can be done only by an expert, or a series of laboratory tests may be needed In any event the doctor is likely to develop an inferiority complex and to tell the family "If there were anything possible to do, I would do it" If the doctor confesses his helplessness, of course the people do not seek his services in preventive lines

The people are ready and willing to cooperate with the doctor in an investigation of susceptibility between acute attacks of sickness Whatever examination may be needed, an accurate history is always necessary, and is often more valuable than an expert physical examination A history is not a history until the facts are written and the record placed on file If a mother makes a crude record of certain facts relating to her child's daily life at home, that record has a greater value than a similar record made by an expert physician and nurse in the artificial environment of a hospital or sanitarium

When a mother keeps such a record of her child, she will expect the doctor to make use of it, but the initiative must come from the doctor

It is not sufficient that a family doctor advise a parent to take a child to a specialist, for the first thing the expert will ask for will be an accurate history What must be the mother's opinion of her family doctor when he cannot answer the simple questions of the case history which the specialist emphasizes? The general practitioner has the opportunity to restore himself to the honored position of family doctor, provided he shows himself to be interested in the individuals during health as well as in their acute diseases

The people a half century ago had confidence in their family doctor because he "Understood their constitutions" The modern doctor will acquire the same reputation when he practices the periodic health examination

---

LOOKING BACKWARD

This Journal Twenty-Five Years Ago

Reciprocity in Medical Licensure This Journal of November, 1906, contains an editorial on reciprocity in licensure, which says

"The preliminary education required for admission to the medical schools must be the same in each State, and the certification of the education department of the State as to standards maintained by secondary schools will be accepted by the education department of other States The effect of this agreement between licensing medical bodies will be to harmonize the requirements for admission to the other professions, thus bringing about reciprocal relations between the stronger States in the licensure in law, dentistry, pharmacy, veterinary medicine, etc

"The agreement between the State mentioned is undoubtedly the beginning of a movement in the direction of medical reciprocity which will spread from State to State until the State lines, so far as the legal right to enter into medical practice goes, shall be obliterated It is fortunate that this movement has begun with the high standard of New York State as the index of requirements, and we are glad that our own regents have been instruments in inaugurating this important action"

The fulfillment of the prophecy regarding uniform medical licensure throughout the United States is as remote as ever New York has reciprocity with eight States,—California, Delaware, Indiana, New Jersey, Ohio, Utah, Virginia, and Wisconsin

MEDICAL PROGRESS

Intracranial Extension of Sinus Infections Treated by Roentgen Therapy.—According to E. J. Hirtz, unquestionably objective anomalies have been revealed by many roentgenograms of the skull which could not be interpreted otherwise than as an index of increased density of certain tissues (fibrosis, calcification, hyperostosis) due to the irritant action of chronic infections which, originating in the deep sinuses, have penetrated into the cerebral ventricles and the midbrain, possibly by way of the cerebrospinal fluid. Such infection, generally occurring very early, and expressing itself in acute attacks at intervals during the course of the life, has given rise to troubles of slow, progressive development. Prominent among the symptoms, in addition to chronic coryza and posterior sinusitis, are headaches of various intensity, including migraine; vertigo, neuralgia, auditory and ocular disturbances, psychic and motor troubles, epilepsy, vascular spasms, vago-sympathetic disturbances, and various glandular symptoms. Treatment in such cases consists of irradiation by rather deeply penetrating roentgen rays (0.30 m. spark-gap), well filtered (0.5 and 1 mm. aluminum); dosage per field very weak. Four portals of entry are used, limited by a leaf of anti-*x*-ray perforated tissue: one frontal, two temporo-sphenoidal, of about 40 sq. cm. each, and one much larger in the occipital and upper cervical region. Sittings given twice a week may be continued over a long period (100-200 sittings) without any injury to skin or blood. The rays reach not only the deep sinuses but also the brain and its integuments. In the great majority of cases the treatment causes no reaction; if such appears at the outset, it is mild and disappears rapidly. Hirtz has used this treatment on over 200 patients since the beginning of 1925. In 35 the symptoms have entirely disappeared; improvement has been striking in 70, definite in 33 others; slight in 18, none at all in 2; there was intolerance in 2, and in 17 the treatments have as yet been insufficient. Disappearance of headaches and migraine has been especially striking in 59 of 74 cases. The soothing effect upon the nerves has been one of the most notable results. On an average it takes 3 months to show a distinct improvement. The favorable response of psychoneuroses opens up interesting perspectives for psychiatry.—*Bulletin de l'Académie de Médecine,* July 7, 1931.

Modified Prolonged Sleep Treatment in States of Depression.—A report is made by Ferdinand Segerath and Theo. Wember on 80 mental patients whom they have treated by the prolonged sleep method. Of these, 21 were suffering with schizophrenia, 9 with various psychoses (mania and paranoia), 1 with severe hysteria, 1 with compulsion neurosis, and 48 with states of depression, including simple melancholia, melancholic insanity, and depressions of the climacteric and postclimacteric. The results were not very satisfactory in the schizophreniacs, but were considerably better in states of depression of the cyclic series, in simple melancholia, and in depression of the climacteric, three-fourths of whom showed improvement or cure. The treatment lasted 12 to 15 days, and was as follows: At 7 a.m., 0.4 gm. phanodorm; 10 a.m., 0.3 gm. luminal; 1 p.m., 0.2 gm. phanodorm; 3 p.m., 15 gtt. somnifen (replaced at a later time by 0.2 gm. luminal); 6 p.m., 0.4 gm. somnacetin; 8 p.m., 0.3-0.5 gm. veronal. It is to be noted that an innovation was used in the substitution of less dangerous substances for the somnifen usually employed. More powerful substances must be used in the insane than in normal persons, since the former have a morbid insensibility toward irritants of the vegetative nervous system. It is important that the patients be awakened at intervals and set upright in bed for their nutriment, to promote better aeration of the lungs and to prevent danger of hypostatic affections. No patient over 55 should be given the treatment, nor any person suffering with cardiac, pulmonary, or renal debility. As a test of the profoundness of the sleep the reaction to a call was found more satisfactory than the corneal reflex. Even in the modification used by the authors the sleep treatment is a method not devoid of danger. It should accordingly be undertaken only upon strict indications, and the patients should be carefully watched by a trained personnel. Relatives should always be informed of the degree of danger to life involved. The treatment should be undertaken only when the disease is very severe and when the alternative of a long or permanent stay in an institution has to be taken into account. There is good reason to expect that safer methods of applying the therapy will by degrees be achieved, as a wider experience demonstrates the best combination and strength of the drugs to be employed—*Deutsche medizinische Wochenschrift,* July 10, 1931.

Tuberculosis and Morale.—W. Froehlich, writing in the *Schweizerische medizinische Wochenschrift* of August 1, 1931, declares that there is a general conviction today that the first symptoms of a tuberculous lesion do not appear

until long after the contamination has occurred, being awakened to activity by one or another occasional factor. Among such factors the chief are of a mental or psychic nature. A study of the history of many tuberculous patients reveals a mental factor as the cause in more than 75 per cent of cases. The parallelism of tuberculosis and mental misery is apparent to anyone who makes a systematic examination of the social, familial, intellectual, and moral conditions of these sufferers. The removal or relief of the psychic factor determines the removal or relief of the tuberculous manifestations, and conversely, the reappearance of the former is capable of provoking a relapse. Ancient and modern writers have drawn attention to the pernicious rôle played by that state of mind commonly defined by the word "disgust." The study of conjugal tuberculosis has clearly established that tuberculosis of the wedded partner was the result not only of contamination by cohabitation but also of a state of mind rendered unhappy by discords and material difficulties Many victims of this disease are subjects who are by nature hyperemotive and who suffer with exaggerated susceptibility. Modern teaching places them among the neuropathic and sympathicotonic. The classification matters little; the essential thing is the fact that an excess of emotionality and sensitivity, plus an intellectual exhaustion, overworks the nervous system if not compensated by intervals of repose and contentment. The same hyperemotivity is habitually present in the parents of the subject and in the general family atmosphere; thus he finds in his family not only the germ of the disease but also a constitutional mental atmosphere which will favor its development. The same observations apply to adolescents. The state of mind of the child and that of his associates exercise an immense influence upon his health, and especially upon his predisposition to tuberculosis. The physician should examine the mental condition of every tuberculous patient as one of the principal causes of the disease, and should provide an adequate therapy, taking into account not only the patient but also his origins, environment, associates, family, and his daily occupations and preoccupations.

Cancer, a Compensatory Phenomenon in the Organism.—In order to understand the genesis of cancer, says Erich Simons, writing in the *Schweizerische medizinische Wochenschrift* of July 11, 1931, we must first establish what we mean by predisposition, by the influence of irritation at a given place, and by the significance of irritation in the development of cancer. We must know why irritation without predisposition does not produce cancer, and vice versa. In Simons' opinion irritation has been incorrectly judged according to its action, when the really important thing is the reaction, the response of the organism. Irritation is of no interest until the organism answers back. The word provocation is more exact in this connection. The organism responds to the provocation with a process of regeneration. We know that a regenerative process that will not come to a halt may result in a cancer. Cancer predisposition may properly be termed an absence or lack of trephones in the organism—the name given by Carrel to the substances contained in embryonal cells, which promote growth processes. In the organism predisposed to cancer these important substances are wanting. If a wound will not heal, it may be assumed that an absence of trephones is thereby shown, which is accordingly a presupposition for cancer development. Thus the observation of processes of regeneration may make the early diagnosis of cancer possible; in other words, it may establish predisposition. Irritation is of interest to the student of cancer only as giving opportunity for a regenerative process. If trephones are wanting, and an irritation is applied to the organism at any point, we may deduce that the latter sends cells of higher function to the site of injury to replace the functions of the weakened cells. The increased function is shown sooner or later in a proliferation of cells. This is the beginning of cancer, which is, accordingly, only a compensatory phenomenon. These replacement cells which do compensatory work are called by Simons precancerous. They do not always lead to cancer, for we know that spontaneous healings can occur. The increased function of these cells is definitely for the purpose of supplying the wanting trephones to the body. This explains why spontaneous tumors are not readily transplantable into a healthy organism: the latter has no need of more powerfully functioning cells.

Late Results of Operative Treatment in Toxic Goiter.—In a follow-up of 42 patients who had been operated upon for toxic goiter, Charles S. C. Don found that there were 18 in whom exophthalmos had been well marked. In five of these patients this symptom was absent, in 11 it was much improved, while in two there was no change; in these, toxic symptoms were still present. He concludes that the disappearance of exophthalmos does not necessarily follow the complete relief of hyperthyroidism, yet a diminution of toxicity is usually followed by an improvement in this sign. Exophthalmos is likely to persist in those cases in which the metabolism has not dropped to within normal limits. Nervousness and tremor, which were present to a greater or lesser degree in every case before operation, were greatly improved in 39 of the 42 patients. The majority of patients gained in

weight after the operation, yet occasionally an otherwise successful result was not accompanied by any increase. Failure to gain in weight is at times associated with glycosuria, which is sometimes seen in Graves' disease, and may become more severe after operation. In only 23 of the 42 patients in this series was the metabolic rate determined before operation. In 21 of these 23 patients there was an immediate fall in the rate after operation. There are cases in which the metabolic rate remains above normal limits in which no increase of thyroid tissue can be detected, and in which no focus of sepsis can be discovered; worry and too little leisure are probably the factors which prevent a good result in these cases. Removal of one lobe of the thyroid was followed by relief of hyperthyroidism in three cases in this series. A satisfactory result also followed ligation in two cases, so that the complete operation was not required at a later date. Ligation alone is not regarded as a curative measure, and while it is of interest to note that a normal metabolic rate can follow this simple procedure, it is probable that the operation had little effect on the ultimate outcome. If the clinical condition of the 42 patients, their ability to do work, and the rhythm and rate of the pulse are considered in conjunction with the basal metabolic rate, the result of operative treatment has been good in 28 cases, with improvement in nine, while in five the operation has been of little value.—*British Medical Journal,* August 15, 1931, ii, 3684.

Anesthesia in the Second Stage of Labor in Primiparæ.—Jane . King and Joyce Morgan, writing in *The Lancet,* August 15, 1930, ccxxi, 5633, present a study of the comparative safety and efficiency of chloroform-ether, a mixture of chloroform (2 parts) and ether (3 parts), and nitrous oxide-oxygen in the second stage of labor in primiparæ. In each case a record was kept of the character, duration, and frequency of the pains, pulse rate, and fetal heart rate, and the condition of the mother and child after delivery. The tabulated results of the investigation indicate that there is a definite advantage in the use of gas oxygen in the second stage of labor. Relief of pain was evident in all cases. Uterine contractions increased in length and efficiency in 50 per cent of the cases. There was a definite decrease in the length of the second stage with gas and oxygen in comparison with the other anesthetics employed. There were no deleterious after-effects on the mother, and no serious effects on the child, though slight cyanosis was not uncommon. The anesthetic is pleasant to take, easy to give, and the depth is readily controlled. The disadvantages are the expense, the special apparatus, and the fact that the services of an anesthetist are required. The method employed was as follows: A mixture of four parts of nitrous oxide and one part of oxygen was given at first, the proportion of the two gases being varied to meet the needs of the individual patient. The patient was instructed to take two deep breaths of the mixture at the beginning of each pain, administration being continued throughout the contraction. Toward the end of the second stage, deep anesthesia was required, and the anesthetic was continued between the pains. The percentage of oxygen was increased at this point, because if the patient were allowed to become cyanosed there was a chance of the infant being rather blue.

The Rôle of Grippe in the Genesis of Fatal Infections in Puerperal Women.—H. Pigeaud calls attention, in the *Journal de médecine de Lyon* of August 5, 1931, to a relation existing between epidemics of grippe and the mortality from infection in obstetrical services. On the basis of 33 such cases that he has personally observed during 10 years at the Lyons Charité, he states that a certain number of women already infected with grippe at the time of their arrival at the hospital die of influenzal septicemia soon after their delivery. An interesting feature in six of the cases was the uterine and periuterine localization of the infection. During epidemics of grippe the increased mortality among these women is especially marked. This is due to the existence of (*a*) endogenous puerperal infection carried through the blood stream, and (*b*) exogenous puerperal infection, transmitted by neighbors or attendants who are carriers. The infection may be due to the influenzal virus itself, but frequently it is apparently due to a streptococcus rendered hypervirulent by its association with the pathogenic agent of grippe. During the winter of 1918 a total of 32 women who died with generalized puerperal infection represented a mortality of 25 per 1,000 puerperal cases. During the same epidemic the general grippe mortality in Lyons was approximately only 2 per 1,000 of population. The contrast between these two rates shows what a dangerous period the puerperium is for women during an epidemic of grippe, and what an increase of mortality results among lying-in patients under such conditions. That the high mortality was not due to the fact of hospitalization with its milieu essentially favorable to infection is proved by that fact that in the surgical wards of the same hospital the mortality from grippe was only 4 per 1,000. One is therefore justified in saying that influenzal infection runs a particularly severe course in puerperal women, and frequently terminates fatally. In several of the author's cases, the infection was observed to begin in the nasopharynz and a few days later to become localized in the periuterine tissues, which from that time on became the cen-

ter of the picture. The interest of these cases lies in the fact that they appear to prove the reality of puerperal infections by way of the blood stream, thus constituting true endogenous infections which to a certain extent defy such prophylaxis as is ordinarily exercised in obstetrical cases.

Why Terminal Cancer?—S. S. Marchbanks, writing in the *Southern Medical Journal*, September, 1931, xxiv, 9, asserts that it is largely the fault of the public that so many persons are dying of cancer. While the public is becoming more and more interested, it has not yet arrived at the point where it can be separated from enough money to supply the seriously needed hospitals for cancer work. Further, the profession as a whole is not prepared accurately to diagnose, and even less to treat, cancer. It is believed that the fact that we do not know the specific cause of cancer is largely responsible for the failure to raise money for hospitals. For the information of possible donors of hospitals and for the purpose of getting on with a program of treatment while waiting for a fundamental discovery, Marchbanks states that cancer is caused by irritation, mechanical, chemical, thermal, and the irritation of infection. The first three are predisposing causes, infection being the immediate cause. The irritants break down the normal defenses and allow the entrance of micro-organisms which produce the direct irritation to the cells, leading to an exaggeration of the repair mechanism. The number of different kinds of germs likely to be implicated in the process is very great. The personal habits of the individual which are more or less necessitated by the stress and strain of modern life are the principal factors tending to produce cancer. However, moderation, temperance, simple life, and physical examinations once a year will go far toward prevention. It is the consensus of opinion among those who have made a study of the facilities the world over for cancer service that a very definite improvement in the service must precede any substantial progress in cancer control. The new methods of cancer therapy require deliberate conference between the surgeon, the pathologist, and the roentgenologist. These three, assisted by members of other branches, can give the best service only when they can work in properly equipped institutions and hospitals. Dr. James Ewing, with Drs. Greenough and Gerster, acting as a committee of the American Society for the Control of Cancer, have recommended a plan for cancer service, which includes cancer institutes strategically situated and costing about $10,000,000 each. Affiliated with the larger institutes there should be special cancer hospitals, state, municipal, university, and private, as well as organized cancer service in general hospitals. As to the treatment of cancer the people need to know that the authoritative consensus of opinion is that the family physician is the key man, that diagnosis must be made earlier, and that the only treatments thus far justified are surgery, radium, and *x*-rays.

The Relations between Vascular Lesions, Exostosis and Traumata.—Writing in the *Riforma medica* of July 27, 1931, E. Fiorini describes a case that presented unusual difficulties of diagnosis, with reference to a claim for industrial insurance. A stonemason, 29 years of age, with a history of malarial and syphilitic infection but with negative Wassermann reaction, a heavy smoker and drinker, bearing an exostosis of the left humerus on the median surface of its upper third, said to be of 10 years' duration, had lately received a blow from a falling beam on the external surface of the same humerus, and likewise at its upper third. Shortly afterward he began to perceive disturbances throughout the entire limb, with arrest of arterial circulation and threatened gangrene of the hand. The question to be decided was, which of the etiological factors cited (malaria, syphilis, nicotine, alcohol, trauma, exostosis) could be held responsible for the disturbances of arterial circulation. Upon surgical removal of the exostosis, the humeral artery, which was almost without pulsation, was found transformed into a hard cord, but was so disposed as not to have undergone any compression or stretching. Rarely is an exostosis alone the cause of circulatory disturbances, and the lack of improvement after its removal dismissed it from the list of possible causes. On the other hand a course of vasodilator and antiluetic treatment, combined with rest, massage, and diathermy, produced distinct benefit. The arsenobenzols were avoided because of the labile state of the vascular apparatus. With the antiluetic mercury and bismuth was associated a treatment with acetylcholin, atropine, histamine and sodium citrate, to diminish the viscosity of the blood. Disappearance of the pains, reappearance of the obliterated pulse, restoration of the part to nearly normal conditions, confirmed the utility of the treatment adopted. But it is impossible to exclude the possibility of the nicotine and alcoholic intoxication having predominated over the luetic factor, or that the time elapsed between the lues and the appearance of endarteritic symptoms might seem too brief. Furthermore the Wassermann was not positive, and the antisyphilitic treatment alone did not suffice to cure the case. None of these etiologic and pathogenetic considerations can be disregarded when one reflects that these forms of gangrene are those which offer hope for the success of physical and pharmaceutical treatment.

LEGAL

CONFIDENTIAL COMMUNICATIONS—AN INTERESTING CASE

By LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

"A person duly authorized to practice physic or surgery, or a professional or registered nurse, shall not be allowed to disclose any information which he acquired in attending a patient in a professional capacity, and which was necessary to enable him to act in that capacity; . . ."

This language is taken from Section 352 of the Civil Practice Act of the State of New York. The statute is a wise and salutary one. It has been stated by one of the higher courts of this State that the purpose of the statute is to "protect the relationship of physician and patient, and to save the patient from possible disclosure by his physician which might result in his embarrassment or disgrace. It was supposed that the good accomplished by preventing disclosures by a physician and by inspiring confidence between patients and their physicians would outweigh the injustice in particular cases which might be caused by the exclusion of the physician's testimony under the provisions of such statute."

Certain statutes or ordinances of this State impose upon the physician a legal duty to report to the health authorities the presence of contagious diseases. But suppose a physician acting in good faith, with a view to the protection of others, reports the disease to a person other than the health authorities, can it be said that he has thereby violated the statute safeguarding confidential communications? We do not know of any reported case on this subject in the State of New York, but in one of our Western States the court had occasion to pass upon this interesting question on the following state of facts:

The plaintiff, who was an employee of a large corporation, was stopping at a small hotel in a town in the West operated by a Mrs. B. He was a stranger in the town. Becoming afflicted with sores on his body, he consulted the defendant who was the hotel physician and the family doctor of Mrs. B. The physician took his history from the plaintiff, gave him a thorough physical examination and informed him that he had reason to believe that the disease from which the plaintiff was suffering was syphilis. The physician stated, however, that it would be impossible to be positive without Wassermann tests, but that he had no equipment for making these tests. He also advised the plaintiff of the danger of communicating the disease to others at the hotel and requested him to leave the hotel, which the plaintiff agreed to do.

The next day the doctor called upon Mrs. B, who was ill, and discovered that the plaintiff had not kept his promise and was still at the hotel. The physician then told Mrs. B that he thought the plaintiff was afflicted with a contagious disease, warning her to be careful and to take particular care of his bed linen, etc. The woman, heeding the warning, fumigated the room, put the plaintiff's things out into the hallway and forced him to leave the hotel.

Going to another town, the plaintiff consulted a second physician who made a single Wassermann test which was negative. The patient then sued the first physician claiming that the law absolutely forbids the disclosure of any confidential communication under any circumstances, and that the breach of the duty of secrecy gives rise to an action for damages in the patient. At the trial the facts were undisputed. The second physician testified on the trial that a single Wassermann test was not conclusive as to the presence or absence of syphilis, and further that the defendant had acted reasonably upon the history and symptoms under the circumstances. At the close of all the testimony the court directed a verdict in favor of the defendant physician, and the plaintiff appealed.

In the State in which the case arose, the statute on confidential communications was contained among the acts of unprofessional or dishonorable conduct justifying the revocation of a physician's license. In the language of the statute, such a license could be revoked where there was a "betrayal of a professional secret to the detriment of a patient." The court defined the purpose of the statute in question to be as follows:

"By this statute it appears to us, a positive duty is imposed upon the physician, both for the benefit and advantage of the patient, as well as in the interest of general public policy. The relation of physician and patient is necessarily a highly confidential one.

It is often necessary for the patient to give information about himself which would be most embarrassing or harmful to him if given general circulation This information the physician is bound, not only upon his own professional honor and the ethics of his high profession, to keep secret, but by reason of the affirmative mandate of the statute itself A wrongful breach of such confidence and a betrayal of such trust, would give rise to a civil action for the damages naturally flowing from such wrong '

The court then took up the interesting question as to whether under the facts of this case the statute was subject to any qualifications or exceptions It should be kept in mind that in this situation there was no positive express legal enactment imposing upon the physician the strict duty to report the disease in question to the person to whom this information was communicated In holding that the decision of the court exonerating the physician was correct and that no liability attached to the physician in the case under consideration, the appellate court said

"The doctor's duty does not necessarily end with the patient, for, on the other hand, the malady of his patient may be such that a duty may be owing to the public and, in some cases, to other particular individuals Recognition of that fact is given by the statutes in this State which delegate power to the State Board of Health, and to municipalities generally to require reports of, and provide rules of quarantine for, diseases which are contagious and dangerous

"When a physician, in response to a duty imposed by statute, makes disclosure to public authorities of private confidences of his patient, to the extent only of what is necessary to a strict compliance with the statute on his part, and when his report is made in the manner prescribed by law, he of course has committed no breach of duty toward his patient and has betrayed no confidence, and no liability could result

"The statute making the 'betrayal of a professional secret' misconduct on the part of a physician is in derogation of the common law and should be strictly construed We believe, the word 'betrayal' is used to signify a *wrongful* disclosure of a professional secret in violation of the trust imposed by the patient

"No patient can expect that, if his malady is found to be of a dangerously contagious nature, he can still require it to be kept secret from those of whom, if there were no disclosure, such disease would be transmitted The information given to a physician by his patient, though confidential, must, it seems to us, be given and received subject to qualification that, if the patient's disease is found to be of a dangerous and so highly contagious or infectious a nature that it will necessarily be transmitted to others, unless the danger of contagion is disclosed to them, then the physician should, in that event, if no other means of protection is possible, be privileged to make so much of a disclosure to such persons as is necessary to prevent the spread of the disease A disclosure in such case would, it follows, not be a betrayal of the confidence of the patient, since the patient must know, when he imparts the information or subjects himself to the examination that, in the exception stated his disease may be disclosed "

The court then pointed out that in order that such a privilege of making a disclosure be available to a physician, he must have had ordinary skill and learning as a physician and must have exercised ordinary diligence and care in making his diagnosis, otherwise he could have been subjected to an action for negligence in making a wrongful report The court further laid down three tests to be used in *determining whether the physician would* be free from liability in a situation of this kind First, that he must prove that a disclosure was necessary to prevent the spread of the disease, second, that the communication was to one who it was reasonable to suppose might otherwise be exposed, and third, that he himself acted in entire good faith, with reasonable grounds for his diagnosis and without malice

We believe that the decision under the circumstances here disclosed is a sound one It appears patent that to hold a physician liable under the circumtances of this case would be to work an injustice, not only upon him, but upon the public as well It is, of course, impossible to say whether the decision would be followed by our New York courts if the question were squarely presented to them It should be noted that the statute in the Western State upon which this decision was based made "a betrayal of a professional secret to the detriment of a patient" an act of misconduct on the part of the physician, whereas the New York statute forbids a physician to disclose any information acquired by him in a professional capacity It would seem, however, that the decision in question would be a persuasive precedent in favor of the physician if the question were squarely raised in one of the courts of this State

NEGLIGENT TREATMENT OF EMPYEMA

A boy about ten years of age was stricken with pneumonia and was under the care of his family physician for about two weeks when the boy developed signs of empyema. The family physician upon discovering this called in the defendant, a physician and surgeon who specialized in surgery. He diagnosed the case as one of empyema and suggested an operation. The parents consenting, the boy was removed to the hospital where the doctor made an incision between the ribs and drained considerable pus. He attended the child until the boy was able to return to his home about two weeks later.

Several days thereafter the child's temperature rose to 103 and the defendant was again called to treat the boy by the physician who was attending him at his home. The defendant doctor probed the wound carefully and there was evidence of an obstructed pus pocket. He advised immediate *x*-rays, and it was agreed that an *x*-ray should be taken and the pictures submitted to him. This was never done, however, and the defendant never saw the child again in a professional capacity.

Thereafter suit was instituted against the defendant doctor to recover damages for alleged malpractice. It was claimed that at the time of the call at the child's home the defendant had negligently inserted his fingers into the incision which had been made in connection with the first operation, without washing or cleaning his fingers in any way, and that he had pushed the ribs apart and twisted his fingers around in the child's body in search of pus, causing the child great agony and a resulting infection. It was claimed that by reason of such negligence a subsequent operation had become necessary to remove pus. The action came on for trial before a judge and jury and the evidence on both sides having been submitted, the jury rendered a verdict in favor of the defendant, terminating the matter in the doctor's favor.

ALLEGED NEGLIGENT TREATMENT OF TONSILS

The defendant in this case, a general practitioner, was called to attend a three-year-old girl whom he found to be in bed suffering from fever and sore throat. The doctor after examining the child found a condition of badly diseased and inflamed tonsils and prescribed certain medications and ordered cold compresses for the neck and forehead. The patient responded to the treatment and the inflammation subsided but the fever persisted. The doctor tested the child's urine and found that she was suffering from pyelitis. He prescribed certain other medicines and her condition improved.

Some time later he was again called to attend the child and found similar symptoms together with a condition of abscess on the middle ear. The ear condition was treated and improved promptly, and the pyelitis subsided satisfactorily. The child, however, continued to suffer from tonsil trouble and the doctor advised the removal of both the tonsils and adenoids. This was consented to. The doctor in charge of the case brought a throat specialist into the case who performed an operation removing the tonsils and adenoids, which operation was uneventful. Some time later the child was brought into the first doctor's office, the parents complaining that the child had a running nose and a swelling in the neck. He prescribed the application of hot camphorated oil on cotton. At this time he advised the parents he feared there was possibly an abscess in the throat for which the doctor expected to return to treat further, but the child was taken by his parents to a doctor who supplanted the physician who originally had charge of the case.

Some time thereafter a suit was instituted against both the first doctor and the surgeon who operated, in which it was claimed the operation was negligently performed and that both doctors were negligent in failing to disclose to the parents of the child the fact that the adenoids and tonsils were not completely removed by the said operation, and that because of the negligence by the defendants, surgical treatment had been necessary for the child. Investigations showed that about four months subsequent to the operation a retropharingeal abscess had developed in the child's throat which had been incised, but which had promptly healed up.

The case came on for trial before a judge and jury and after all the evidence had been put in, the plaintiff having failed to convince the court that there was any failure on the part of the defendants to follow approved practice, the court, on motion of the defendant, dismissed the complaint.

NEWS NOTES

EXECUTIVE COMMITTEE

The regular monthly meeting of the Executive Committee of the Council of the Medical Society of the State of New York was held on the afternoon of Thursday, October eighth. Reports from the several standing and special committees were received.

Venereal Diseases: Dr. James N. Vander Veer, liaison officer in venereal diseases with the Division of Social Hygiene of the State Department of Health, gave a report of his activities along the lines described on page 712 of this JOURNAL of June 1, 1931. Since April he had visited the following fifteen county societies accompanied by Dr. Albert Pfeiffer, Director of the Division of Social Hygiene of the State Department of Health:

Cortland	Schoharie	Yates
Onondaga	Seneca	Jefferson
Ontario	Tompkins	Rockland
Otsego	Warren	Washington
Saratoga	Wayne	Sullivan

In addition he addressed the Suffolk County Medical Society and Dr. Pfeiffer addressed the Herkimer and Columbia County Medical Societies. Dr. Vander Veer's report continues:

"While we were on these trips we have visited local clinics, and have consulted and advised the health officer and local doctors of the changes in laws and procedures, especially those requiring physicians to report the diseases as contagious, and those providing for compensation for doctors treating patients who are unable to pay. It has been the policy of the Committee to inform doctors of the provision of the law requiring the community to provide the means by which the doctor is assured of his pay.

"A doctor need not treat cases in his private practice beyond their ability to pay and thus carry them as nonpaying or indigent cases later, for the law now puts the nonpaying or indigent type of case squarely upon the local health officer to treat or provide treatment, at the expense of the local board of health. In a few instances a local health officer has informed his board of health that he could not adequately treat syphilis, or was unfamiliar with its treatment, and through his records and recommendation, funds have been voted by the local board of health for such treatment, and outside physicians have benefited economically.

"In a number of instances, the local health officer would prefer to see such an arrangement made whereby some physician better acquainted with the diagnosis of syphilis would take this upon himself for the extra economic gain. Or again, we have interested some physicians in taking up the study of syphilis in the smaller communities, to which the local health officer, or board of health can refer these cases and thus the patients get earlier, better, more systematic, and longer treatment, as we know is now necessary for the control and cure of this disease—to the betterment of the community, the control of the disease, and to the increased income of a doctor.

"We have also told physicians that they can obtain standard makes of the arsphenamines of soluble and insoluble bismuth, and in needed cases tryparsamide, free from the Division of Social Hygiene of the State Department of Health, in return for which they are simply asked to report at the end of each month how many packages they have drawn and the number of cases treated, so that the Division may, in this manner, be kept advised as to whether the cases are receiving sufficient treatment.

"In our talks before county societies, and with individuals, we have stressed the importance of a dark field examination of each suspicious lesion; and of the necessity of a Wassermann on all persons seen for the first time in the regular first physical examination made; and of Wassermann examination in every case of suspected syphilis, every case of gonorrhea, and every case of chancroid, over a period of time, thereby hoping that as physicians we may pick up quickly the 'silent case,' especially in pregnant women, which may so readily be a spreader of infection, or from the congenital type which may thus saddle later upon a community, and upon us as tax payers, the latent cardiovascular, and neuro-syphilides, now crowding our local and state institutions, to say nothing of our recognizing the disease in its inception.

"We have been called upon to answer many questions extraneous to our talks, mostly of economic bearing; and having spoken in rural counties mostly, we believe the frequent visitations of state and district society officers, who keep themselves up by contact and reading with the present day trend of medical practice in its social and economic features, will do much to advance the position of the everyday doctor, who is at present at sea in his thoughts as to his rights and privileges."

Press Publicity: A Press Publicity Committee was appointed in accordance with the action taken

by the House of Delegates on June first (see this JOURNAL, July 1, 1931, page 830). The resolution provided for a Special Committee of sixteen members, two from each District Branch. Those appointed by the Executive Committee were as follows:

Samuel J. Kopetzky, Chairman.

First District:
Samuel J. Kopetzy, New York
Edward C. Povdin, Bronx

Second District:
Alec N. Thomson, Brooklyn
Carl Boettiger, Long Island City

Third District:
James N. Vander Veer, Albany
Arthur J. Bedell, Albany

Fourth District:
Edwin MacD. Stanton, Schenectady
Leo F. Schiff, Plattsburg

Fifth District:
Hyzer W. Jones, Utica
Lynn B. Chase, Morrisville

Sixth District:
Charles D. Ver Nooy, Cortland
Arthur S. Chittenden, Binghamton

Seventh District:
Walter A. Calihan, Rochester
John R. Williams, Rochester

Eighth District:
Louise Beamis, Buffalo
Peter J. Di Natale, Batavia

This committee was given general powers to devise its own methods of investigation and procedure in "providing the press with authentic medical news and placing the views of organized medicine before the public."

Committee on Public Health and Medical Education: Dr. Thomas P. Farmer, Chairman of the Standing Committee on Public Health and Medical Education, reported on the activities of the committee during the months of June, July, August and September.

Poliomyelitis: Dr. Farmer's committee and a sub-committee of experts, cooperated with the State Department of Health in organizing the physicians of the State under their county societies, as described in the JOURNAL of August 15, 1931, page 1048. The services were planned along three lines:

1. Medical Society meetings for discussing the subject of poliomyelitis.

2. Immune serum, its collection, control, and use.

3. A consulting diagnostic service.

Meetings were immediately arranged for all the county societies in the region of the Hudson River. These meetings were addressed by Dr. George Draper, whose services were secured by the State Department of Health. The meetings, however, were arranged by Dr. H. L. K. Shaw for this committee and included the following county societies: Schenectady, Albany, Rensselaer, Saratoga, Warren, Washington, Ulster, Sullivan, Orange and Dutchess-Putnam. Dr. Ayer of Syracuse addressed the counties of Broome, Tompkins, and Chenango. Dr. Ludlum arranged for a meeting in Kings County, and a meeting was held in New York County.

A meeting was also held in Nassau County and was addressed by Dr. Lloyd Aycock of Boston (see page 1048 of the August fifteenth JOURNAL).

"The Medical Society of the State of New York can take credit to itself for the way in which its members prepared themselves to handle a greater outbreak of the disease had it occurred. The sub-committee on poliomyelitis will probably meet once again during the fall to review the records of the disease and make recommendations for the control of future outbreaks."

The sub-committee also issued a statement on the diagnostic signs of poliomyelitis during the pre-paralytic stage, when treatment was most effective. (See this JOURNAL, August fifteenth, 1931, page 1038.)

Governor's Health Commission: On June thirtieth the chairman of the committee met with the Public Relations Committee at which time the latter committee discussed the proposed study of the Report of the Governor's Special Health Commission. The Committee on Public Health adopted the method of dividing this report into sections for study by its individual members. On September eleventh the first meeting of the committee was held in Albany for this purpose and it voted to join with the Committee on Public Relations as one committee for this study.

Graduate Education: The graduate courses to be given to county societies during the fall of 1931 are as follows:

Monroe, Pre-clinical Medicine, September 21, 1931. (With Livingston, Genesee and Ontario.)

Rockland, Internal Medicine, October 14 and 23, 1931.

Cortland, Traumatic Surgery, October 16, 1931.

Schoharie, Dermatology and Syphilology, October 13, 1931.

Otsego, Dermatology and Syphilology, October 13, 1931.

Seneca, Traumatic Surgery, October 8, 1931.

Wayne, Traumatic Surgery, October 8, 1931.

At the request of the Schoharie and Otsego County Societies, lectures will be given in their courses each month. The Monroe county course

was arranged especially so as to provide instruction on pre-clinical medicine to the profession preparatory to a campaign in that county for periodic health examinations. The subjects were outlined by Dr. Nellis B. Foster.

The Committee has arranged during the summer for speakers at regular meetings of the Wayne and Greene County Societies and also arranged for speakers in the Fifth, Sixth, and Seventh District Branch meetings. The chairman of the committee has attended meetings of the Wayne and Oneida County Societies, the Executive Committee of the Sixth District Branch, and the annual meetings of the Sixth and Seventh District Branches.

The Committee on Public Health and Medical Education has suffered a great loss in the sad and sudden death of Dr. John O. Polak. Because of his vast knowledge of matters of public health and medical education he was an unusually helpful member in the work of the committee. It is not too much to say that a large part of the credit for any real accomplishments of the committee belong to him. Dr. Polak's record as a member of the committee stands out because of his faithful and devoted attendance at the committee meetings. He was never absent unless he was a long distance away from New York State by reason of attendance at some scientific meeting; never allowing private work to interfere with what he felt was his obligation to the State Society. He willingly accepted tasks no matter how inconvenient or difficult they might be to handle. The Committee most of all will miss Dr. Polak, however, because of his agreeable personality and pleasant companionship.

JOINT COMMITTEE ON THE GOVERNOR'S HEALTH COMMISSION

The Joint Committee on the Report of the Governor's Health Commission held its second meeting on Thursday, October 8, 1931, in the building of the New York Academy of Medicine, with fourteen members present. The Committee devoted the greater part of the session to a consideration of the broad features of the proposal for the establishment of a county health department in every county that shall take the place of the present system of a local board of health in every village and town. The recommendations of the Governor's Commission on the County Health Unit appears on page 1211 of the October first issue of this Journal.

The Joint Committee plans to hold sessions in several sections of the State and to invite representatives of the County Medical Societies to be present and express their views on any or all the subjects discussed in the report of the Governor's Health Commission. Ample notice of the sessions will be sent to the societies in order that the members may prepare themselves with constructive suggestions.

The Committee requests that each physician or delegation prepare and present a written abstract of the plans and arguments that are advanced, in order that they may be clearly understood and recorded.

The following schedule of hearings has been arranged:

October 27—Hotel Statler, Buffalo, at 2 P.M.
November 10—Hotel Syracuse, Syracuse.
November 17—DeWitt Clinton Hotel, Albany.
November 24—New York City.

MEDICAL FILMS, 16 mm. SIZE

Moving pictures on medical subjects have a recognized value, and are used more and more widely with the increasing number of those available. Moreover, the use of the sixteen millimeter film brings the movies within the reach of the smaller societies, for two reasons:

1. Projectors are available in every village.
2. The film is non-inflammable and may be shown without restrictions of permits or licenses.

County medical societies and hospital staffs would doubtless use the sixteen millimeter medical movies frequently if they had a list of films from which to choose. The best list, and indeed the only comprehensive one, that has come to the attention of the editors of this JOURNAL, is that compiled by the Educational Division of the Bell and Howell Company, 1801 Larchmont Avenue, Chicago, Illinois, manufacturers of moving picture apparatus. The company has issued a mimeographed list of twenty-six pages containing descriptions of 362 films. It also gives the names and addresses of forty-eight producers of the films, and the prices for their sale or rental. Some excellent films are owned by commercial companies, who will send the films free of charge and even supply a projector and an operator. At the other end of the scale are films for sale only, at prices ranging from a small sum to over one hundred dollars. The films are divided into two classes:

1. Technical, for medical men.
2. Popular, for lay audiences and students in public schools and colleges.

An indication of the scope of the professional pictures is shown by the following list from the first two pages of the catalogue:

Alpha Film Laboratories, 4 films on cell development.

Amateur Cinema League, Inc., eight films on a variety of medical topics for exchange among the members.

American College of Surgeons, fifteen films.

American Heart Association, a film on the acting valves of a steer's heart.

American Society for the Control of Cancer, the "Canti" film, and one on living cancerous cells.

The list is by no means complete, for it includes only those which are publicly listed as generally available to all who apply. The Bell and Howell Company does not deal in the films, or assume any obligation for supplying them; but will send the mimeographed catalogue to any county medical society that will apply for it; or to any health organization that sponsors public meetings.

An editorial suggestion is that every secretary who sends for the catalogue shall preserve it with care, ready for use on a moment's notice.

A similar list of dental films is also available.

FIFTH DISTRICT BRANCH

The twenty-fifth annual meeting of the Fifth District Branch of the Medical Society of the State of New York was held on September 29th, in the Marcy State Hospital, at Marcy, near Utica, with 170 members registering and over 200 in all present. The large attendance was undoubtedly due partly to the fine weather. Some of the Watertown doctors flew to the meeting by airplane—something new in medical transportation in New York. The President, Dr. A. B. Santry, presided.

An address of welcome was given by Dr. William W. Wright, Superintendent of the Marcy State Hospital.

The following papers were read:

"Pernicious Anemia, Differential Diagnosis and Treatment," Kenneth R. McAlpin, M.D., New York City.

"Modern Methods of Treating Syphilis of the Nervous System," Charles W. Hutchings, M.D., Marcy State Hospital.

Joseph Colt Bloodgood, M.D., Baltimore, Md., talked on cancer for one hour and forty minutes, and held everyone's attention closely with lantern slides.

An address on "Some of the Compensation Problems Encountered in Surgical Practice," by Percival K. Menzies, M.D., and a talk on "Compensation Law and the Physician," by Mark A. Daley, General Secretary, Associated Industries of New York, Buffalo, N. Y., closed the session. There was considerable discussion from the floor on most of the papers.

Dr. W. D. Johnson, President of the State Society, Dr. D. S. Dougherty, Secretary, and Dr. John A. Card, Speaker, explained some of the problems of the State Society.

At the election held following the luncheon at one o'clock, Edward R. Evans, M.D., Utica, was moved from First Vice-President to President, William A. Groat, M.D., Syracuse, from Second Vice-President to First Vice-President. Le Roy Hollis, M.D., Laconia, N. Y., was elected Second Vice-President.

Dr. Fred C. Sabin, M.D., was elected Secretary in place of William J. McNerney, M.D., Syracuse, who held the office twelve years.

Hermann G. Germer, M.D., was re-elected Treasurer.

RURAL MEDICAL PUBLICITY

One of the poliomyelitis consultants for the State Department of Health in one of our rural counties reports the following incident illustrating how news can travel in rural sections.

"Making a call with a local doctor about thirty miles from town, we found patient "A," a small boy, suffering with meningitis following internal ear infection, and decided to send him to the hospital. The doctor asked me to go with him to see patient "B" from whom he had just received a call for suspicious poliomyelitis. On arriving at the home of patient "B," I undertook to telephone to the hospital about the meningitis patient. The telephone was on a party line with some twenty extensions, and the following conversation attracted my attention:

"There's one case has it up at the corner. The doctor put a sign up yesterday, and Brown's has it too, I guess. They had Dr. C. yesterday for two of them, and there's two more sick there today, I hear. I haven't seen

the doctor there yet today. And I hear they've got it at B.'s and are going to have the State Doctor."

"Yes, he's there now with Dr. A. and a nurse. Don't you think they ought to close the schools?"

It was necessary to interrupt the talk and ask for a chance to use the telephone. When the message to the hospital was put through, it was almost impossible to hear or to be heard. The local doctor said that was because as soon as the "State Doctor" put in a call, every receiver on the line was down and the whole countryside listened in. Quarantine placards, he stated, were practically unnecessary, as the telephone broadcast spread the news so rapidly. By the way, patient "B" did not have "it."

WASHINGTON COUNTY

At the Washington Medical Society meeting at the Hudson Falls Court House on October 6th, Dr. Russel C. Paris, of Hudson Falls, one of the older practitioners of the county, having received his degree in 1883, was presented with a memorial in the form of Da Costa's "Modern Surgery." The book was inscribed with a dedication as follows:

"Presented to Dr. Russel C. Paris by the Medical Society of Washington County as a token of their respect and esteem for him as a man and a physician. Also in grateful appreciation of his long and faithful service as a member and officer of this society. Official record: Treasurer from 1911 to 1920 inclusive; vice-president in 1921; president in 1922; treasurer from 1923 to 1930 inclusive."

The book was autographed by all the physicians present as follows: B. C. Tillotson, president; Silas J. Banker, secretary; Charles A. Prescott, treasurer; D. F. MacArthur, J. Leonard Brynes, W. C. Cuthbert, William L. Munson, W. A. Leonard, H. W. Gillette, Denver M. Vickers, John H. Ring, Arthur E. Falkenbury, J. E. Armstrong, Z. V. D. Orton, Samuel Pashley, Jr., L. R. Oatman, Samuel Pashley, J. T. Park.

Dr. Samuel Pashley, Sr., who was the chairman of the committee in charge of the memorial, made the presentation, and Dr. Paris responded.

S. J. BANKER, *Secretary.*

GREENE COUNTY

The annual meeting of the Medical Society of the County of Greene was held on October 13th at the Kaksakee Inn in Coxsackie, N. Y., with fifty per cent of the membership present. Dinner was served at 6.45 o'clock. The President, Dr. Atkinson, presided, and the business session was held immediately after dinner.

There was no scientific session, it being felt by the officers that there were several matters of interest that should be attended to, and that if proper consideration was to be given, all the time available would be required.

Reports were received from the Chairman of the Legislative Committee, and the Committees on Public Relations and Public Health. The Treasurer reported the financial condition of the Society.

The Chairman of the Public Relations Committee introduced a resolution requesting that the Board of Supervisors appoint physician members of the Public Health Nursing Committee from a list submitted by the Society; and that in the future arrangements be made for the payment of physicians conducting clinics, as had been done in the past in certain cases; also urging the appointment of physicians to membership in the various lay organizations engaged in Public Health Work.

A second resolution was introduced by the same Committee urging uniform fees for medical school inspections, pre-school examinations and immunization clinics.

After a thorough discussion these resolutions were adopted.

An amendment to the by-laws was offered by Dr. Rapp, whereby the term of office of the officers of the society would be two years instead of one.

The following recommendations relative to County Health Departments were adopted:

1st. Approval of the fundamental idea of County Health Units.

2nd. That all counties under 30,000 be permitted to have a full-time County Commissioner of Health.

3rd. That all Health Officers be retained in office at the discretion of the county board of health.

4th. That a majority of the county board of health be physicians.

5th. That only cities be excluded from County Health Units.

6th. That county boards of health meet at least every two months for the consideration of health matters.

W. M. RAPP, *Secretary.*

DUTCHESS-PUTNAM

A dinner meeting of the Dutchess-Putnam Medical Society was held Wednesday evening, October 7, 1931, at the Nelson House, Poughkeepsie, N. Y. The officers of the Medical Society of the State of New York were entertained. There were addresses during the evening by Drs. William D. Johnson, President, D. S. Dougherty, Secretary, C. Gordon Heyd, T. P. Farmer, F. E. Sondern, J. N. VanderVeer, Joseph D. Lawrence, and John A. Card. Doctor William A. Krieger presided.

The meeting adjourned at 11:00 P.M.

The following members and guests were present: Drs. J. N. VanderVeer, F. E. Sondern, R. P. Folsom, D. S. Dougherty, C. Gordon Heyd, T. P. Farmer, William D. Johnson, Joseph D. Lawrence, Albert Pfeiffer, Dineen, C. T. Caldwell, C. E. Lane, G. S. Tabor, C. O. Davison, H. St. John Williams, R. H. Breed, Nelson Borst, John I. Cotter, M. Gosse, C. K. Deyo, J. J. Toomey, James Harrington, J. F. Rogers, L. E. Rockwell, C. A. Crispell, A. W. Thomson, H. Percy Dawe, Earle W. Voorhees, V. A. Bacile, Aaron Sobel, H. P. Carpenter, H. A. Benson, Donald Malven, W. A. Krieger, E. G. MacKenzie, J. E. Sadlier, G. E. Lane, J. M. Cronk, John A. Card, J. H. Dingman, E. A. Stoller, M. B. Morrison, B. E. Roberts, T. J. Morrison, H. Weston, B. Stibbs, J. N. Boyce, H. J. Christensen, W. T. Rivenburgh, J. Coborn, and Mr. Charles Murray—50 in all.

H. P. CARPENTER, M.D., *Secretary.*

COLUMBIA COUNTY

A special meeting of the Columbia County Medical Society was held on September 22, 1931, for the purpose of considering the advisability of recommending to the Board of Supervisors, the establishment of a County Health Department. The following resolution was passed:

"Resolved, that the Columbia County Medical Society go on record as in favor of the establishment of a County Health Department, to include the entire county, under the provisions of the present County Aid Law applying thereto, on the conditions that four of the members of the County Board of Health be chosen from a list of its members selected by the County Medical Society and also that the county's share of the expense shall not exceed the present cost of administration of health activities in the county."

L. VAN HOESEN, *Secretary.*

The annual meeting of the Columbia County Medical Society was held on October seventh, in the Worth House, Hudson, beginning at 11 o'clock. The following officers were elected:

President: Samuel James Post, Philmont.

Vice-President: S. V. Whitbeck, Hudson.

Secretary-Treasurer: L. Van Hoesen, Hudson.

Censors: W. D. Collins, L. J. Early, N. D. Garnsey, E. Niver, L. M. Niesen.

Dr. G. E. Stevens was elected to membership.

After a noon luncheon the following scientific program was carried out:

Cases of Undulant Fever: Dr. L. J. Early.

The Importance and Interpretation of Chemical Studies of the Blood, Dr. Arthur Wright.

Moving Picture: The Diagnosis and Treatment of Infections of the Hand.

L. VAN HOESEN, *Secretary.*

RENSSELAER COUNTY

A meeting of the Medical Society of Rensselaer County was held on the evening of October 13, in the Medical Center in Troy, N. Y. Dr. W. B. D. Van Auken was appointed reporter for the Society.

Dr. A. J. Hambrook, past delegate to the State Society, spoke of the desirability and advisability of a county society retaining its delegates, if they are good ones, from year to year. He stressed the importance of the delegate's actual attendance at the State meetings.

The attention of the Society was called to a recent advertising scheme of a newspaper published in a nearby city. It was pointed out that complimentary biographies of physicians could be published in the columns of this paper for $25.00.

Some of the members had been inviegled into the scheme. A warning was issued.

Dr. Edward H. Hume of the Harvard Medical School, gave an address on "The Significance of Graduate Study to the Practitioner." Dr. Hume emphasized the social and community effects that will follow the demonstration and application of scientific medical developments in the daily practice of physicians. Dr. Hume said: "Medicine does not mean scientific contacts primarily, but a social relationship which can be furthered only when public confidence in the doctor is thoroughly entrenched."

Dr. W. Irving Walsh of Troy discussed "The Present Status of Syphilis."

Dr. Harry W. Carey spoke on the subject of "Hereditary Syphilis."

W. B. D. VAN AUKEN, *Reporter.*

NASSAU COUNTY

The first regular meeting of the fall season of the Medical Society of the County of Nassau was held on the evening of Tuesday, September 29, 1931, at the Garden City Hotel, with about 75 members present. As is the custom of the society, the meeting was preceded by an informal dinner at 7:30 o'clock.

The scientific session was furnished by two excellent men. Robert A. Cooke, M.D., Assistant Professor of Applied Immunology at Cornell Medical College, spoke very completely on allergy, enumerating the many manifestations which we now know to be of allergic nature. He offered concise and worthy suggestions for diagnosing and managing such conditions.

William L. Sneed, M.D., Attending Surgeon at the Hospital for Ruptured and Crippled, New York City, and Consulting Orthopedic Surgeon at Nassau and North Country Community Hospitals in Nassau County, delivered a timely address on the after-care of poliomyelitis. He stressed the hopeful prognosis of the cases which have occurred this summer where early immobilization was secured in the paralyzed part, followed by proper massage, and quoted excellent results from the newer surgical procedures familiar to all orthopedic surgeons.

Dr. Ernest Dickey, of Rockville Center, reporting for the Public Health Committee, stated that in Nassau County to date were 214 cases of poliomyelitis, with a mortality of 15. Serum had been administered to 130 pre-paralytic children.

Resolutions were adopted thanking the Long Island Lighting Company for donating a Drinker Respirator for the use of physicians of the county in combatting bulbar cases of poliomyelitis, and thanking the North Country Community Hospital for the excellent way in which it handled the 34 cases of poliomyelitis which were admitted to the hospital.

H. G. WAHLIG, *Secretary.*

SULLIVAN COUNTY

The annual meeting of the Medical Society of the County of Sullivan was held at the Lenape Hotel, Liberty, N. Y., on October 14, 1931.

The meeting was preceded by a dinner which was tendered to the Society by its President, Dr. J. M. Rosenthal of Monticello, N. Y.

At the business session which followed the dinner, the following officers were unanimously elected to serve for the ensuing year.

President: J. M. Rosenthal, M.D., Monticello.
Vice-President: George F. Herben, M.D., Loomis.
Secretary-Treasurer: Luther C. Payne, M.D., Liberty.
Board of Censors: V. G. Bourke, M.D., Livingston Manor, N. Y.; S. W. Wells, M.D., Liberty; J. H. Moore, M.D., Loomis; Harry Jacobs, M.D., Hurleyville; Benjamin Abramowits, M.D., Monticello.
Chairman on Public Health and Relations Committee: Harry Golembe, Liberty.
Chairman of Committee on Legislation: R. S. Breakey, Monticello.
Delegate to State Society for Years 1932 and 1933: L. C. Payne, Liberty.
Alternate: R. S. Breakey, Monticello.

A heated discussion on ethical "advertising," especially as it relates to the peculiar conditions existing in Sullivan County during the summer, was held. Dr. Herben of Loomis was appointed a committee of one to draw up a resolution in regard to this matter,—the resolution to be presented and discussed at the next meeting of the Society.

The Society voted to have as its next postgraduate course a group of six lectures on internal medicine. These lectures will be delivered by eminent specialists from New York. The secretary was also instructed to try and arrange a course of lectures on physio-therapy. The chair appointed as a committee of arrangements Dr. Harry Golembe, Liberty, Dr. J. H. Moore, Loomis, and Dr. Benjamin Abramowits, Monticello.

HARRY GOLEMBE

THE DAILY PRESS

LEISURE FOR THOUGHT

An editorial writer in the New York *Times* of October 15 comments on the opportunity for thought afforded by enforced leisure and says:

"Some philosophers have seen in the prolonged depression the incidental benefit of causing many people to use their brains as they never did before. It is undoubtedly true that there is a new army of thinkers abroad in the land. Never were there so many of what Carlyle called 'great thoughts' put forward as a solution of all our troubles. Panaceas are, in fact, thicker than blackberries.

"Among so many it might seem invidious to single out one. But the originality of the proposals put forward by one analyst of our woes fairly demands their citation. One of them is the adoption of a 'universal calendar.' This is recommended as one of the ways to bring about the 'actual end of the present world business depression.' Another is adjustment of the world's currencies to a 'Universal Numismatic Standard.' Still more striking, and presumably effective, is 'The Equalization of the Barometric Systems of the World.' This work alone is guaranteed to 'employ millions from all classes.' Only a bold man would deny this—if he understood at all what was meant.

"Truly this is an age of self-expression. But the question is whether the self-expressers have anything worth expressing."

SEA FOOD

The New York *Herald Tribune* of September-13, has an interesting editorial on the abundance of the leading sea foods in the New York markets, and says:

More than a hundred varieties of sea food have a commercial value in the United States, according to the most recent tabulation by the Bureau of Fisheries of the Department of Commerce, but twelve of these groups constitute 80 per cent of the entire annual yield of more than 2,600,000,000 pounds. Of first importance is the salmon, basis for the gigantic canning industry of the Pacific Northwest, while the second on the list is the pilchard, which in California is canned as a sardine. Haddock is only the third in importance and is used mainly for the manufacture of filets, now widely shipped by the fresh and frozen fish trade. Sea herring, the Maine sardine, is fourth in order; oysters, the gourmet's delight, are fifth, while shrimp, cod, mackerel, flounder (customarily the basis for "English sole"), tuna fish, halibut and crabs complete the list.

YOUTHFUL OLD AGE

An editorial in the New York *Times* of Octobe 16 comments on an address by Dr. Mayo at the American College of Surgeons, on the subject of prolonging life, and says:

"When the Sibyl was promised by Apollo anything that she might ask, she took a handful of sand and said: 'Grant me to see as many birthdays as there are grains of sand in my hand.' But she forgot to ask for enduring youth, and her body shrank with the years till she was lost to sight and nothing remained except her sayings. So if the years which Dr. Mayo says have been added to the average life by taking thought—that is, by giving heed to hygienic and medical science—have given more birthdays to millions, they have not brought freedom from age's withering touch.

"Tennyson's Tithonus asks as a gray shadow:

"Why should a man desire in any way
To vary from the kindly race of men,
Or pass beyond the goal of ordinance
Where all should pause, as is most meet for all?"

"But the answer is the passion for life almost universally strong in man even in death. And science has, after all, not only robbed the added years of labor and sorrow, but made them the crowning glory of life.

"What causes greatest anxiety for many is the fear not of the 'destruction that wasteth at noonday,' which one can fight in the open, but of the insidious diseases that walk in darkness (referring to cancer).

"As for extending youth with the years, that can be only if, as Dr. Mayo says, 'we begin to care for our health in early life.' To be young when old, one must be old when young."

VITAMIN, THE FAIRY

One would think that vitamins were intelligent fairies, judging by the panegyrics written in their honor by popular health authors. James J. Montague praises them in the following matter-of-fact verses in the *New York Herald Tribune* of September 9:

"Unseen, unhonored and unsung,
In times beyond our ken
When our now aging race was young,
You've been the friend of men.
You've never flinched nor begged for terms,
You've never sought repose,
But sternly battled with the germs
That were your mortal foes.

"Man never knew, when he lay ill,
Afraid that he might die
From some mephitic form of chill,
That you were standing by,
The role of ally to assume—
In unrelenting strife
To hound the microbes to their doom
And thus to save his life.

"But all the while, like guards on post,
Through anguished days and nights,
You've flung yourselves upon a host
Of microscopic mites.
You never asked as much of him
As three good grateful cheers
When your amazing pep and vim
Prolonged his earthly years.

"But now your worth we recognize;
We know that day by day,
Infinitesimal though your size,
You hold the germs at bay.
But though we praise and honor you
And your heroic brood,
There's nothing we can ever do
To show our gratitude."

PSYCHIATRIC EXAMINATIONS

The New York *Times* of October 14 comments editorially on the impracticability of some psychiatrists, and gives examples as follows:

"A 'psychiatric social worker' struggled to analyze a 'problem boy' who was unhappy, unmanageable and always getting into fights. His father and mother were the white janitors of an apartment house for colored people in Harlem. After five weeks of tests, the investigator decided: 'It begins to look as if there would have to be a change of environment.' Another boy who didn't get on well at school was taken to a clinic where he was submitted to intelligence tests, emotional tests, test of his reflexes, and a thorough going-over of his school and family history. Finally, an examination revealed that he needed eye-glasses.

"In the examination of a man whose commitment for insanity was sought, a New York jurist halted proceedings to say that the pronouncement of the experts 'doesn't mean much to me.' 'What's wrong with this man, anyway?' The reply was: 'He has no insight into his condition.' 'Then half the people in the world must be crazy,' replied the judge, and the man was discharged.

"When elaborate 'happiness tests' in college laboratories reach such astounding conclusions as that happiness and health 'tend to accompany each other,' and that worry, ill health and sex difficulties generally cause unhappiness 'in even the smallest groups,' a protest against ponderous hocus-pocus and high-sounding verbiage seems in order."

NEW CHEMICAL ELEMENT

News of a scientific discovery is sometimes found in the daily press before it is available in scientific journals. The New York *Herald Tribune* of October 16 carries the announcement of the discovery of element 87, leaving out number 85 not yet identified among the 92 possible ones listed in the chemistries. The discovery was made by Dr. Jacob Papish, professor of spectroscopy in Cornell University, working with a mineral called samarskite. The *Herald Tribune* says:

"Samarskite is a mineral rich in rare alkalis. It is found in Norway, Siberia, a[illegible] States of this country. Element No. 87 has certain definite characteristics. It is an insoluble solid and cannot be isolated because of its high inflammability. It is unusually sensitive to light, and because of this fact it may have interesting possibilities for use, say, in connection with photo-electric tubes, and the like.

"Its presence in the samarskite sample used was in such small proportion, one part element 87 to 2,000,000 parts of the material, that Professor Papish believes it will never be abundant in the [illegible]"

BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.

CLINICAL DIETETICS: A Textbook for Physicians, Students and Dietitians. By HARRY GAUSS, M.S., M.D. Octavo of 490 pages, illustrated. St. Louis, The C. V. Mosby Company, 1931. Cloth, $8.00.

AMERICAN PHYSICIANS AND SURGEONS: A Biographical Directory of Practicing Members of the Medical Profession in the United States and Canada. Prepared by JAMES CLARK FIFIELD. Quarto of 1737 pages. Minneapolis, The Midwest Company, [1931]. Cloth, $30.00.

A TEXTBOOK OF MEDICAL DISEASES FOR NURSES INCLUDING NURSING CARE. By ARTHUR A. STEVENS, A.M., M.D., and FLORENCE ANNA AMBLER, B.S., R.N. Octavo of 503 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1931. Cloth, $2.75.

A CLINICAL STUDY OF ADDISON'S DISEASE. By LEONARD G. ROWNTREE, M.D., and ALBERT M. SNELL, M.D. 12mo of 317 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1931. Cloth, $4.00. (Mayo Clinic Monographs.)

PROCTOSCOPIC EXAMINATION AND THE TREATMENT OF HEMORRHOIDS AND ANAL PRURITUS. By LOUIS A. BUIE, B.A., M.D. Octavo of 178 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1931. Cloth, $3.50. (Mayo Clinic Monographs.)

SURGICAL CLINICS OF NORTH AMERICA. Volume 11, No. 3, June, 1931. (New York Number.) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues): Cloth, $16.00 net; paper, $12.00 net.

THE ANATOMY OF THE NERVOUS SYSTEM from the Standpoint of Development and Function. By STEPHEN WALTER RANSON, M.D., Ph.D. Fourth edition. Quarto of 478 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1931. Cloth, $6.50.

COLLECTED PAPERS OF THE MAYO CLINIC AND THE MAYO FOUNDATION. Edited by MRS. H. M. MELLISH-WILSON, RICHARD M. HEWITT, B.A., M.A., and MILDRED A. FELKER, B.S. Volume XXII, 1930. Octavo of 1125 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1931. Cloth, $13.00.

INJURIES AND SPORT: A General Guide for the Practitioner. By C. B. HEALD. Octavo of 543 pages, illustrated. New York, Oxford University Press, 1931. Cloth, $8.00. (Oxford Medical Publications.)

GOULD'S MEDICAL DICTIONARY containing the words and phrases generally used in medicine and the allied sciences, with their definition, pronunciation and derivation. By GEORGE M. GOULD, A.M., M.D. Third edition, revised and enlarged, based on recent medical literature. Edited by R. J. E. SCOTT, M.A., B.C.L. Quarto of 1538 pages, illustrated. Philadelphia, P. Blakiston's Son & Company, Inc., 1931. Fabrikoid, Plain, $7.00; with Thumb Index, $7.50.

MEDICINE, SCIENCE AND ART: Studies in Interrelations. By ALFRED E. COHN. Octavo of 212 pages. Chicago, The University of Chicago Press, 1931. Boards, $4.00.

CUNNINGHAM'S TEXTBOOK OF ANATOMY. Edited by ARTHUR ROBINSON, M.D., F.R.C.S. Sixth edition. Quarto of 1554 pages, illustrated. New York, William Wood and Company, 1931. Cloth, $11.00.

DIAGNOSIS IN JOINT DISEASE: A Clinical and Pathological Study of Arthritis. By NATHANIEL ALLISON, M.D., F.A.C.S., and RALPH GHORMLEY, M.D. Quarto of 196 pages, illustrated. New York, William Wood and Company, 1931. Cloth, $11.00.

MEDICAL CLINICS OF NORTH AMERICA. Vol. 15, No. 1, July, 1931. (Mayo Clinic Number.) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues): Cloth, $16.00 net; paper, $12.00 net.

DISEASES OF THE GUMS AND ORAL MUCOUS MEMBRANE. By SIR KENNETH GOADBY, K.B.E., M.R.C.S. Fourth edition. Octavo of 496 pages, illustrated. New York, Oxford University Press, 1931. Cloth, $13.00. (Oxford Medical Publications.)

THE CAUSATION OF CHRONIC GASTRO-DUODENAL ULCERS: A New Theory. By J. JACQUES SPIRA, M.R.C.S., L.R.C.P. Octavo of 78 pages. New York, Oxford University Press, 1931. Cloth, $2.50. (Oxford Medical Publications.)

ENCEPHALITIS LETHARGICA: ITS SEQUELAE AND TREATMENT. By CONSTANTIN VON ECONOMO. Translated and adapted by K. O. NEWMAN, M.D. Quarto of 200 pages, illustrated. New York, Oxford University Press, 1931. Cloth, $6.00. (Oxford Medical Publications.)

FRACTURES OF THE JAWS. By ROBERT H. IVY, M.D., D.D.S., and LAWRENCE CURTIS, A.B., M.D. Octavo of 180 pages, illustrated. Philadelphia, Lea & Febiger, 1931. Cloth, $4.50.

A TEXTBOOK OF PATHOLOGY. By FRANCIS DELAFIELD, M.D., LL.D., and T. MITCHELL PRUDDEN, M.D., LL.D. Fifteenth edition, revised by FRANCIS CARTER WOOD, M.D. Octavo of 1339 pages, illustrated. New York, William Wood and Company, 1931. Cloth, $10.00.

MODERN PROCTOLOGY. By MARION C. PRUITT, M.D., L.R.C.P. Octavo of 404 pages, illustrated. St. Louis, The C. V. Mosby Company, 1931. Cloth, $8.00.

CUTANEOUS X-RAY AND RADIUM THERAPY. By HENRY H. HAZEN, A.M., M.D. Octavo of 166 pages, illustrated. St. Louis, The C. V Mosby Company, 1931. Cloth, $3.00.

COMMUNICABLE DISEASE CONTROL. Report of the Committee on Communicable Disease Control, George H. Bigelow, M.D., Chairman. White House Conference on Child Health and Protection. Octavo of 243 pages. New York, The Century Co., [c.1931]. Cloth, $2.25.

BOOK REVIEWS

THOMSON & MILES' MANUAL OF SURGERY By ALEXANDER MILES, M D, LL D, and D P D WILKIE, M D, F R C S Eighth edition Volume 1, General Surgery 12mo of 574 pages, illustrated New York and London, Oxford University Press, 1931 Cloth, $3.80 (Oxford Medical Publications)

This is the first volume, devoted to General Surgery of the eighth edition of a well known manual It is deserving of highest praise Concise, detailed, well illustrated and excellently phrased, it is highly recommended as a text book to all medical students and as a table reference book to the practitioner

GEO WEBB

A TEXTBOOK OF MATERIA MEDICA FOR NURSES By GEORGE P PAUL, M D, C P H Sixth Edition, thoroughly revised Octavo of 356 pages Philadelphia and London, W B Saunders Company, 1930 Cloth $1 75

As a textbook for nurses this excellent volume deserves a place among the standard works on this subject It is well written, concise, and gives the student nurse in a practical way exactly what she is required to know regarding this important branch of medicine In addition, it does not burden the student with a lot of material that is beyond her comprehension, a fact that is so often lost sight of by authors and teachers

F S

HANDBOOK OF THERAPEUTICS By DAVID CAMPBELL, M A, M D 12mo of 411 pages New York and Edinburgh, William Wood & Company, 1930 Cloth, $4 50

This book is a valuable asset to the library of both student and practitioner It embraces, in concise form the salient facts regarding modern therapeutics There are chapters devoted to diet, biological products, physical methods of treatment, and the use of water, heat, cold and climate as therapeutic agents

The various chapters devoted to the specific infectious diseases and those of the nervous system, heart, lungs, kidneys, etc, are of special interest to those who want a quick and ready reference without reading the more voluminous textbooks on this subject

F S

BACTERIOLOGICAL TECHNIQUE A Laboratory Guide for Medical, Dental, and Technical Students By J W H EYRE, M D M S Third edition Octavo of 619 pages, illustrated New York, William Wood & Company, 1930 Cloth, $7 50

This book is an excellent addition to any laboratory library and is invaluable to the advanced student or technician in bacteriology The author gives in exact detail the more advanced unusual procedures as well as those in common use The work is profusely illustrated

It is rather surprising, however, that the author does not mention such subjects as the typing of pneumococci nor the Widal and Wassermann reactions

I COHN

THE INTERNATIONAL MEDICAL ANNUAL A Year Book of Treatment and Practitioner's Index Editors CAREY F COOMBS M D, and A RENDLE SHORT, M D Forty ninth Year, 1931 Octavo of 551 pages, illustrated New York, William Wood and Company, 1931 Cloth, $6 00

It is manifestly impossible for a reviewer to discuss more than but a few of the many topics summarized in this latest issue of the Medical Annual Whatever the virtues or shortcomings of these many novel remedies may be, one is left with the impression of ceaseless energy in all branches of medical practice A cursory review of the material shows much of it to be in the nature of repetition of well established data There are, however, a number of articles which do reflect a distinct progressive trend

The routine use of digitalis in lobar pneumonia is now disparaged as being useless and dangerous, while formerly its omission in the regimen of the pneumonia patient would have been regarded as ignorance or criminality Dextrose seems to win praise in definitely lowering the mortality rate of that disease

Rickets seems to be becoming more and more complicated with the growth of pediatric research The latest addition to medical terminology is renal rickets, a rare symptom complex

Medical students and practitioners often fail to recognize the potential seriousness attending every contusion of the eyeball but rely on external signs in judging prognosis Detachment of the retina is one of the serious considerations of every ophthalmologist, and in recent years a number of successes in replacing this detachment have been effected by the galvano cautery method of Gonin

Scarlet fever antitoxin which prematurely gained such prominence as a reliable therapeutic agent is now dealt with rather cautiously

In the prophylaxis of tuberculosis the BCG vaccine of Calmette is subjected to much criticism' in spite of the fact that about 400 000 infants have been vaccinated without apparent ill results

The treatment of burns by spraying a freshly made aqueous solution of 2½% Tannic acid until the skin has become tanned is now widely adopted

The problem of giving insulin by mouth is definitely set at rest with the terse statement that "at present there is no other way of therapeutic administration of insulin but with the needle '

There are encouraging reports on the beneficial effects of r ray therapy in selected cases of Pituitary tumors

EMANUEL KRIMSKY

INSOMNIA An Outline for the Practitioner By H CRICHTON-MILLER, M A, M D Octavo of 172 pages London, Edward Arnold & Company, New York, Longmans, Green & Company, 1930 Cloth $4 20

Genial well written, interesting, and admirably printed The author grants we know nothing of sleep,—and yet discusses it at length and with great wisdom Mental harmony adjustment equilibrium balance stability are emphasized as prerequisites of slumber Many cases are noted, some in detail and English in type His literary jottings range all the way from Kipling and Yale locks to French quips, with sly play of humor In fact his style is more French much as some Americans since the War love an Anglo philiac pose

His choice of hypnotics when forced to use them is duly conservative, though he takes little account of arterial or psychic tension, i e, of physiologic suitability

His inability to give material aid to the depressed (cyclothymics) is more frank than encouraging, though he incidentally notes the grave danger in the common practice of urging travel

He makes extensive references to Pavlov Freud and Jung and a brave effort to find some use of their theories to his field

A table of Contents and a consulting Bibliography but no Index

W

MEDICAL CLINICS OF NORTH AMERICA. Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues): Cloth, $16.00 net; paper, $12.00 net.

Vol. 14, No. 1. July, 1930. (University of California Number.)

This issue is contributed entirely by Dr. Lewellys F. Barker and the material is based on lectures he delivered at the University of California in 1929. The first chapter deals with a now rare case of typical Typhoid Fever.

The chapter on Polyposis of the Colon should be of interest to the general practitioner for it depicts in convincing words and by *x*-ray pictures how this malady can be specifically cured by *x*-ray therapy.

The rest of this volume is a clinico-pathologic consideration of certain chronic ravaging diseases which unfortunately do not lend themselves to prevention or to medical treatment. Such diseases include, for example, progressive muscular atrophy, chronic epidemic encephalitis, and cirrhosis of the liver.

Vol. 14, No. 2. September, 1930. (New York Number.)

This issue of the Medical Clinics has been of far more absorbing interest to the reviewer than any of the recent numbers. A number of the common maladies met with in everyday practice are brought to the reader's attention with consistent advice as to their best management. And even though there may not be much in the way of news it is consoling to find some of the established ideas reiterated in systematic practical fashion.

For example, in cases of myocardial disease, Dr. Williams admits that it is a "land of mystery." But an electrocardiogram will occasionally clarify matters. In the chapter on the pathogenesis of peptic ulcer we are again reminded that "quite a large percentage of recurrences occur after medicine or surgery." The chapter on diseases of the thyroid gland is a splendid article on that subject. The practitioner is advised in clear terms when to use iodine and when to avoid it. The writers of this article have witnessed many cases of iodine poisoning and thyroid intoxication from its indiscriminate use. The chapter on "Object Lessons in Pediatrics" has one or two valuable pointers which will offer a surprisingly different outlook to some established routine practices.

Vol. 14, No. 3. November, 1930. (Mayo Clinic Number.)

This issue deals in a practical way with certain of the office cases seen by the average practitioner. The controversial question of the significance of gastric secretion as regards cancer of the stomach is settled by one contributor who holds that "high acidity in the absence of free hydrochloric acid is invariably significant of carcinoma." Duodenal ulcer of the perforating type, it is stated, is most benefited not by medical treatment but by early surgical intervention. Splenomegaly associated with chronic ulcerative colitis is discussed and although the reason for the splenomegaly cannot be accounted for, the writer warns his readers against splenectomies because of the danger of a complicating nephritis.

The comparative responses of various tumors to irradiation are considered and the respective diagnoses interpreted on the bases of these characteristic responses. Typhoid vaccine is conclusively stated to be far less effective in the treatment of neurosyphilis than malarial injections.

There are a number of chapters which may be of academic interest. For example, systemic blastomycosis; electrocardiographic localization of myocardial infarcts; and fistula between the oesophagus and the tracheobronchus.

Vol. 14, No. 4. January, 1931. (Philadelphia Number.)

This number is not quite as instructive or progressive as its immediate predecessors. In fact the average practitioner will take issue with some of the methods advocated for various maladies because they are so directly contrary to established practices and because they seem so impractical. For example, in visceroptosis the writer advises against abdominal supports and instructs his patients to lie generously on the left side and to eat five meals daily.

Not satisfied with our already pregnant terminology one contributor has chosen to make a further contribution in a review of 26 cases which he has diagnosed as "duodenitis," but he admits that the "diagnosis has not been proved in any of these 26 cases." One contributor states that "for more than fifteen years I have used colon (bacillus) vaccine, and I believe that I have seen very definite clinical improvement in certain cases." In the light of increasing skepticism with regards to questionable vaccines what should the attitude of the general practitioner be in the absence of unsupported facts?

One writer convincingly tells us of the need for cystoscopy in suspicious urogenital cases and illustrates by case histories typical clinical mistakes as proven by cystoscopy. And while he urges the more frequent use of the cystoscope he also warns the ambitious worker that the "nephritic, anemic patient beyond the age of 50 . . . is sometimes killed by the passage of the cystoscope."

We often associate achlorhydria with a cancer of the stomach. Hitzrot has studied 100 random cases of achlorhydria and found it to occur very often as part of or in association with gastritis, cholecystitis, neurosis, and other entirely unrelated disorders. Even though he insists that "adequate treatment of achlorhydria demands more than the mere prescribing of hydrochloric acid" he nevertheless includes it as a major part of his treatment. Pepsin is avoided.

Vol. 14, No. 5. March, 1931. (Chicago Number.)

Much of the material in this number is an academic presentation of certain common clinical conditions and the information in general does not deviate much from that of previous numbers.

For example, one chapter records a study of 309 cases of ringworm but the writer does not know its etiology or its treatment. Some of the contributors in the absence of definite means of therapy suggest attacking foci of infection. Possibly an investigation of the effects of the eradication of foci of infection might be a much saner method of research. In the chapter on rheumatic fever we are told that "extraction of one badly diseased tooth was followed by no serious consequence. The extraction of a second was followed by an embolism which terminated the patient's life."

Vol. 14, No. 6. May, 1931. (New York Number.)

The case reports depicted in this issue of the Medical Clinics conform more to the types encountered in everyday clinical practice than a number of its predecessors. Gonorrhœa, rheumatism, pneumonia and their respective clinical features occupy quite a proportion of the text. And while there is nothing strange in the type of information offered it should nevertheless serve to refresh the practitioner's mind with certain important details which may well be forgotten, and at the same time keep him on his guard for some of the more unusual complications which may follow any of these diseases.

The problem of low basal metabolic rates is further evaluated in conjunction with constitutional asthenia without hypothyroidism, such as allergic asthma and psychoneurosis. The ever-interesting problem of renal glycosuria is again interpreted for us from the prognostic standpoint through case reports.

EMANUEL KRIMSKY.

AN INTRODUCTION TO PHARMACOLOGY AND THERAPEUTICS By J A GUNN, M D, D Sc Second edition 12mo of 233 pages New York and London, Oxford University Press, 1931 Cloth, $1 50 (Oxford Medical Publications)

This small book of pocket size provides in a condensed form the principal facts of the subjects of which it treats and is convenient for a quick general review, as for examinations

In this edition there is a new chapter dealing with the action of drugs on the respiratory system and additions to some of the other chapters have been made

W E MCCOLLOM

THE COMMON SENSE OF DRINKING By RICHARD R PEABODY Octavo of 191 pages Boston, Little Brown and Company, 1931 Cloth, $2 00

Whether or not you believe that prohibition is a boomerang which has made drinking fashionable, if you have hit the booze until you can't leave it or take it and are shot to pieces unless you are loaded up, read Mr Peabody's book It holds no brief either for or against prohibition or for the morality of drinking Nor does it undertake to explain the physical ills which may arise from drinking These are subjects which Mr Peabody prefers to leave to what he terms more authoritative sources

There are individuals who can drink normally and safely Others exhibit a reaction to drink so extreme and abnormal that they cannot afford to indulge unless they are willing to sacrifice everything to drink As a result of extended experience in treating chronic alcoholism, Mr Peabody is primarily concerned in showing how the drinker who is slipping his hold on business, health and personal relationships may cultivate abstinence and like it 'It is a far easier task than the alcoholic has any idea of," Mr Peabody asserts

Mr Peabody's approach is psychological His discussion will go far toward helping the 'continuous drinker' and 'the bad actor" to understand themselves Incidentally the book will help the drunkard's family to understand also The book should be of value to general practitioners who may be called upon to be of assistance to patients in any walk of life who, though they would recoil horrified at addiction to the hypodermic needle, need advice about excessive drinking

FREDERIC DAMRAU

PRACTICAL ANAESTHETICS for the Student and General Practitioner By CHARLES F HADFIELD M B E, M A Second edition Octavo of 336 pages illustrated New York, William Wood & Company, 1931 Cloth, $3 50

The author justifies this second edition on the ground that the new methods introduced within the past eight years have materially affected the art if not the science of his subject, even though he decries the tendency toward mechanization ' Inasmuch as the book is written mainly for the student and the general practitioner" its key word is 'simplicity" Yet it is not so simple and rudimentary but that the expert anaesthetist will keenly relish the evident indications of the experience and skill of the author which the manner and method of its matter affords Hadfield's extended service at St Bartholomew in teaching students gives him peculiar qualification to determine what they need to know Likely he had their nebular knowledge in mind when he wrote the "fear of the matter" into the opening chapter "Anaesthetics may, then be regarded as poisons, the use of which demands not only all the skill and knowledge at the command of the administrator, but also the greatest care and attention throughout" So, consistently, while careful explanation is made of the scientific aspect of the subject, the author, page after page, in needed detail takes up the manner, and gives the reason for the manner of the administration In all this the American readers are compelled to think in terms of our own armamentarium, this is of course a bother, and to that extent interferes with ready understanding However to one who knows the subject there is a sympathetic appreciation of the author's triumphs over common difficulties, and the tricks which we must all develop to protect our patients as well as to keep the operator happy

The new subject matter is mainly the recently adopted Ethylene and the several preliminary drugs but particularly four chapters on regional and vertebral methods Hadfield's book is not merely another book it is another good book

A F E

THE HARVEY LECTURES Delivered under the auspices of the Harvey Society of New York, Series 25, 1929 30 Octavo of 225 pages Baltimore, Williams & Wilkins Co, 1931 Cloth, $4 00

With this volume the series of lectures of the Harvey Society of New York attains the quarter of century mark of these publications They form an interesting and valuable contribution to the medical literature of this period This volume, like its predecessors, covers a varied group of subjects such as Water Metabolism, Cardiac Output of Man, Filterable Virus Diseases, Immunity in Syphilis, Pituitary and Thyroid Glands, Pathogenesis of Tuberculosis, Electrical Phenomena in Living Cell These lectures are presented by such well known scientists and teachers as Ernest Pick, E K Marshall Jr, E W Goodpasture A M Chesney, Philip E Smith, Esmond R Long, Winthrop Osterhout In connection with the twenty fifth anniversary of the founding of the Society this volume contains a very interesting lecture by Rufus Cole on the 'Progress of Medicine during the past twenty five years as exemplified by the Harvey Society Lectures"

Comparatively few are privileged and able to attend these lectures but it is fortunate that they are made available in book form to the many who cannot be present to hear them delivered

F

HYPERTENSION AND NEPHRITIS By ARTHUR M FISHBERG, M D Second edition Octavo of 619 pages, illustrated Philadelphia, Lea & Febiger, 1931 Cloth, $6 50

The first edition of Fishberg's Hypertension and Nephritis appeared about one year ago It soon acquired the well deserved reputation of being the most complete and reliable presentation of the subject available The enormous literature was reviewed in a masterly manner, and presented so smoothly that the reader was surprised to find that so many references had been cited, when he came to the table at the end of each chapter (There are over seventeen hundred references in the new edition) This vast material was woven into a story that read simply and clearly It was of course dominated by the author's own experience and judgment and this was done in a very well balanced manner Debatable points were squarely labelled as such, even though the author had an opinion of his own upon the subject On the other hand he did not hesitate to contradict tradition if the evidence pointed to such a conclusion

The new edition incorporates some important developments of the past year It necessitates the enlargement of the book by about fifty pages The teacher or specialist will find in it the most complete exposition of the subject, and the general practitioner clean cut clinical pictures and sound advice

F H

OUR NEIGHBORS

MALPRACTICE SUITS IN TEXAS

The September issue of the *Texas State Journal of Medicine* devotes a lengthy editorial to "The Malpractice Damage Suit," as it affects Texas. While the principles of defense are the same throughout the nation, yet Texas handles the cases somewhat differently from New York. Texas does not begin to have as large a proportion of malpractice suits as New York. The editorial says:

"Before the State Medical Association undertook to defend its members against such unjust damage suits, the industry was not really a very thriving one. Our investigations at the time disclosed that there had been nine suits filed for each of the previous two years. Last year, according to the report of our Council on Medical Defense, eighteen cases were filed. That is a one hundred per cent increase. Doubtless the figures are not accurate in either instance. It is rather customary now for physicians to carry indemnity insurance, and the cases filed against such physicians are not all reported to the Council, for the reason that the Council does not assume financial responsibility in such cases."

The eligibility for defense by the Texas State Society is as follows:

"The Council on Medical Defense is not required to defend cases as they arise. Indeed, it is required to defend only those cases which investigation discloses nonculpability on the part of the defendant physician. It may fairly be concluded, therefore, that when the Council on Medical Defense defends a physician or cooperates with an insurance company in defending him, the defendant is not guilty. There is a vast difference of opinion as to what constitutes guilt in such cases."

Examples of suits are given:

"Nor should any physician feel that he is beyond the reach of the damage suit lawyer. He is not. No physician is who practices medicine, whether general or special. Our records show that a physician was sued for malpractice because he dropped a gum lancet in a child'e eye. There were several cases of suits following burns from water bottles. There is now pending a case for mistreatment for snake bite. A patient reacted unfavorably to potassium iodide, and she sued her physician. A physician performed an autoposy without proper authority. He had been told to go ahead, but not by the proper party. He was sued. Incidentally, few insurance companies will defend such a case. Our Council on Medical Defense decided that it was a proper case for our Council to defend. There is a case pending in which it is alleged that the practicing physician was negligent in the care of a child's eyes at the time of birth. Another physician gave a dose of pituitrin at the time of childbirth, and was subsequently sued for malpractice. These are cases any one of which might easily be that of the average practitioner of medicine."

While the Texas State Society advises every member to take out indemnity insurance, it does not seem to assume the leadership in the choice of the company as New York does:

"The Council does not assume control in cases where there is indemnity insurance. This position of the Council is frequently misunderstood. It is not altogether a matter of saving money, even though it would seem foolish for the Council to furnish additional legal services to those furnished by a reputable insurance company which stands to lose several thousand dollars in the instance of failure. It is deeper than that. Should the Council intervene and assume any part of the control of a case where there is indemnity insurance, the insurance company might easily refuse to pay the indemnity should there be a verdict against the defendant. Always the Council offers to co-operate, and more frequently than otherwise it is given opportunity to do so. Should it be shown that a member is inadequately defended and the member involved is willing to take a chance on the indemnity feature of the case, the Council will not hesitate to take charge of such a case.

"The Council on Medical Defense unhesitatingly advises our members to provide themselves with indemnity insurance. It advises, however, that such insurance be taken out with reliable companies only, and that the policies purchased be carefully read and thoroughly understood. It is of great importance to the insured to know that when his time of trouble comes, there will be money in the hands of the insurance company with which to defend him and to pay any loss incurred through court verdict. . . . . Sometimes insurance companies are so busy with other and more important lines of work that they take little or no interest in such small matters as malpractice indemnity suits. We have known of such cases. It is also important, and most important, that an indemnity policy provide that no compromise should be effected in any case except upon the consent of the policyholder. It is unquestionably a fact, as we have already said, that

(*Continued on page* 1358—*Adv. xvi*)

The new reduced price of Mead's Viosterol in Oil 250 D in the original 50 c.c. bottle now makes vitamin D available to the patient at a cost of only 2 to 2½ cents per day. This economic phase is important at all times but is especially important during times of unemployment and financial stress.

Not only has the price of Mead's Viosterol been reduced, but the bottle has been improved. As packed, it is capped with the metal cap shown at the left. The patient removes this and replaces it with the combination dropper-and-stopper shown in the bottle illustration. This has a screw thread and fits tightly when not in use.

For vitamin D therapy, the new reduced price of Mead's Viosterol when prescribed in the original 50 c.c. bottle, makes it less expensive to the patient than Mead's Standardized Cod Liver Oil or any cod liver oil concentrate. For vitamin A therapy, Mead's Standardized Cod Liver Oil continues to be 4 to 11 times as economical as cod liver oil concentrates.

(*Continued from page* 1356)

success in one suit will tend to produce other suits, either against the same physicians or other practitioners."

The Texas law of statute limitations seems to be different from that in New York.

"It is important that those physicians who carry indemnity insurance preserve their old policies for at least twenty-three years. This advice seemed ridiculous at first thought, but it is a matter of legal limitation as to time. An adult cannot sue a physician for malpractice, for instance, after the lapse of two years. It is different in the case of a minor. The limitation does not begin to apply until the minor has attained his majority. A Texas physician was recently sued for alleged damage to a throat in a tonsil operation several years ago. Plaintiff in the case was twenty-two years old at the time suit was filed, hence only one year of the period of limitation had expired. The defendant in this case carried indemnity insurance at the time of the operation, but he had changed his company several times and had thrown away his old policies."

The Texas Editor advises prevention as more effective than defense, as it says something that New York doctors may well heed:

"In the malpractice scourge, as in contagious diseases, prophylaxis s the thing. There can be little doubt but that a large proportion of malpractice suits are incident to thoughtless or unintended expressions of physicians. Certainly, prophylactic treatment is applicable here. All the physician needs to do is to keep his mouth shut if he cannot conscientiously enter into a defense of his fellow-practitioner. Frequently a physician is so certain of conditions that he fails to take universally used precautions. Ninety-nine times out of a hundred that is all there is to it, but it is the hundredth case in which there is an unfortunate development, which may or may not be the result of negligence. Whether it is or not, the shrewd lawyer can make it appear so."

POLIOMYELITIS WORK IN MICHIGAN

When poliomyelitis threatened the people of Michigan, the physicians immediately responded to an appeal of the State Commission of Health in a way that is described in the October issue of the Journal of the Michigan State Medical Society, as follows:

"On August 20, telephone information came

from Lansing expressing apprehension that a poliomyelitis epidemic was threatening. It was intimated that the State Society might render effective assistance by warning the doctors to be alert and endeavor to make an early diagnosis in suspected cases.

"This cooperation and assistance to the State department of health was immediately accorded in the following manner:

"Within twenty-four hours a poliomyelitis bulletin containing a table of diagnostic symptoms and a request that members be alert when called to suspicious cases was mailed to 3,800 doctors.

"Representatives of the Society met with the Commissioner of Health for the purpose of instituting preventive plans, consultant services and laboratory assistance and the formation of a state commission.

"On August 24 it was deemed desirable to hold an educational clinic and such a clinic was arranged for on the twenty-seventh. Again within twenty-four hours 3,800 cards were sent to our members notifying them of this clinic and the program that would be carried out.

"From the letters received and the response made by our members we feel that this mobilization of doctors throughout the State created a corps of men who were on the alert to abort what promised to be an epidemic of considerable magnitude. It also revealed the Society's willingness to respond to and cooperate with health officials. This response re-affirms the statement frequently made that the greatest success of any health movement or activity is dependent upon the cooperation of the practicing physician—the bedside doctor."

The same Journal describes a commission on infantile paralysis of seven members, and tells of the plans as follows:

"The plan of work of the commission includes providing diagnostic assistance upon request and furnishing convalescent serum for treatment of cases.

"The State has been divided into eight districts, with a regional consultant in charge of each district.

"These consulting physicians are prepared to go themselves or to send a physician who is capable of clinical diagnosis and doing spinal puncture if indicated. Any physician who desires this service should call the regional consultant of his district.

"The collection of blood from convalescent cases for the preparation of serum is being handled for the most part by health officers and rep-

resentatives of the Michigan Department of Health. The serum is distributed at the discretion of the regional consultant. A payment of $10 is made to each donor. The serum is furnished only for pre-paralytic cases, upon a diagnosis confirmed clinically and by spinal fluid test. It is not for sale, and no charge is made for it, but those able to contribute toward its cost are invited to do so. The cost is from $15 to $20 per patient. The supply of serum is limited, and it is not given to cases already showing paralysis or for immunizing purposes.

"One of the first activities of the Commission was the holding of a clinic on infantile paralysis on August 27 at Herman Kiefer Hospital. Between three and four hundred doctors from all over the State attended.

"The work of the commission is being financed jointly by State and voluntary agencies."

BIBLIOGRAPHIES IN NEBRASKA

The question of publishing a bibliography at the end of a medical article is frequently discussed in the State medical journals. The policy of the *Nebraska State Medical Journal* is stated in the July issue as follows:

"That bibliographies are a valuable part of reports of research work need not be discussed—it is freely admitted. Medical editors and publishers have been brought face to face with the problem of space required to publish bibliographies, especially when the references are numerous. To give a specific instance: Very recently we saw an article in an exchange with a bibliography of five and one-half pages in seven point appended. It will be admitted that giving so much space to a bibliography is an injustice to the average reader who is willing to take the facts stated in the body of the article for granted and cares nothing for the bibliography. Several years ago the *Journal of the A.M.A.* declared against voluminous bibliographies and has cut them down to a minimum. The position is taken that if the author desires all the references he may have them appended in the reprints. Space in the *Nebraska State Medical Journal* is not so plentiful that we can afford to publish pages of references to articles. It shall be the policy hereafter to cut references to a possible half dozen or dozen, and authors will kindly govern themselves accordingly."

LIQUID PEPTONOIDS WITH CREOSOTE

COMBINES the active and known therapeutic qualities of creosote and guaiacol with the nutritive properties of Liquid Peptonoids and is accordingly a thoroughly dependable product of definite quantities and recognized qualities as shown by the formula:

Each tablespoonful represents

ALCOHOL (By Volume)	12%
PURE BEECHWOOD CREOSOTE	2 min.
GUAIACOL	1 min.
PROTEINS (Peptones and Propeptones)	5.25%
LACTOSE AND DEXTROSE	11.3%
CANE SUGAR	2.5%
MINERAL CONSTITUENTS (Ash)	0.95%

It acts as a bronchial sedative and expectorant, exhibiting a peculiar ability to relieve *Bronchitis—acute or chronic.* It checks as well a persistent winter cough and without harsh or untoward effect. It is agreeable to the palate and acceptable to the stomach—with merit as an intestinal antiseptic. Supplied in 12 oz. bottles.

THE ARLINGTON CHEMICAL COMPANY

YONKERS, NEW YORK

CHIROPRACTOR IN OKLAHOMA HOSPITAL

It seems incredible that a chiropractor should be given the privilege of treating his patients in a public hospital. Aside from the matter of "schools" and scientific qualifications, there are two cogent reasons that the chiropractor should be excluded from a hospital:

1. Hospitals conform to the standards of the American College of Surgeons—that a complete history of every case be written and kept on file for study, with a diagnosis conforming to a standard list of diseases and conditions, such as that used by the Medical Department of the Army of the United States; and, further, that every case be subject to review at a monthly staff meeting.

2. Physicians have a standard of ethics not only in their conduct toward their patients, but also toward one another; and it is extremely unwise to compel the members of a professional staff of a hospital to recognize as an associate one who lacks the fundamental experience and knowledge which even a trained nurse possesses.

Yet a chiropractor was forcibly injected into the staff of the Hospital of the University of Oklahoma in the manner described in the September issue of the Journal of the Oklahoma State Medical Association:

"On July 27th, 1931, the Governor issued an executive order that a chiropractor be admitted to the University Hospital for the purpose of treating a patient in the free teaching service. This was done immediately after a telephone conversation with Dr. LeRoy Long, Dean, with the Governor refusing to permit Dr. Long to present reasons opposing such an order, and which order Dr. Long protested most earnestly and vigorously. Two or three days later the President of the University advised Dr. Long that the Governor had turned the entire matter over to the Board of Regents to be settled according to law. It was then urged that the President of the University ask the Board of Regents to meet and take action, the President later advising that he was unable to get the Board together."

Then follows a description of the efforts of the authorities of the Hospital to secure a meeting of the Regents, but without success The article continues:

"In the meantime the chiropractor was going to the hospital, students were asking for their credits, interns were greatly disturbed, and the general morale was bad.

"After careful consideration, on August 7th, Dr. Long called the faculty together, briefly went over the situation, telling them he would resign the next day, and advised them to elect a chairman so they might consider the emergency in an orderly manner. This was a very trying time for Dean Long, for about a score of those in the meeting were with the school when he took charge of

it about sixteen years ago. Many feeling speeches were made in which Dr. Long was urged to reconsider his decision. A motion expressing confidence and urging him to remain was passed unanimously, but Dr. Long thought that it was best under the situation, that he resign and for the following reasons:

"1. The Governor had, by a formal executive order, interferred with the fundamental functions of the school and hospital without giving the faculty an opportunity to be heard.

"2. Dr. Long felt that his resignation was the only possible way to secure prompt action by the Board of Regents.

"3. It was necessary to emphasize the actual scope and purpose of legitimate medicine as opposed to the cults.

"The resignation went in August 8th and it was almost immediately announced there would be a meeting of the Board of Regents on August 12th. Dr. Long and his committee, under authority given them by the Council, employed Ex-Justice of the Supreme Court, Thomas H. Owen, who, after exhaustive investigation, prepared a brief in which he stated that, under the law, the cults could not be admitted to University Hospital.

"The Board of Regents met at the School of Medicine on August 12th, and by a vote of 5 to 2 the cults were excluded from University Hospital. Dr. Long's resignation was formally accepted, and Dr. L. J. Moorman, Oklahoma City, a most estimable member of the profession was elected dean.

"It is only fair to say that the President of the University, Dr. Bizzell, as well as the members of the Board of Regents were anxious to do everything legally possible in the interest of the School of Medicine, but apparently, they were unable to understand the necessity of prompt action if the standing of the School was to be preserved."

The Journal praises Dean Long and his inestimable service to the Medical School and medicine generally. Since only sixteen days elapsed between the executive order of the Governor and the meeting of the Regents, it is hard to understand why the Dean retired. However, the article closes:

"Dean Moorman will have the support of every member of the Medical Association of Oklahoma. The cults will be kept out of that school if it is legitimately possible to keep them out, but if they are permitted to enter, its doors will soon be closed as a medical school."

MEDICAL LICENSES IN MICHIGAN

Physicians in the State of Michigan have a separate board for the examining and licensing

(*Continued on page* 1365—*Adv. xxiii*)

Fills the need for a dependable antacid mineral water

VICHY CÉLESTINS

This long renowned naturally alkaline mineral water assists in neutralizing excess acid and in regularizing functions of the digestive tract.

Bottled at the Spring in Vichy, France, under Government supervision, it meets the great need of the physician for constancy of composition.

(*Continued from page* 1364—*Adv. xxii*)

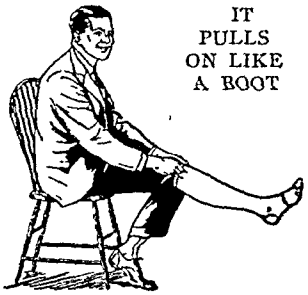
of candidates in fifteen vocations,—accountants, architects, engineers, surveyors, barbers, chiropodists, embalming, dentistry, law, medicine, nursing, optometry, osteopaths, pharmacists, and plumbers. The Committee on Legislation of the Michigan State Medical Society has proposed one central certifying and licensing agency under the control of the State Department of Education. The plan is similar to that of New York State and is set forth at length in the annual reports of the Committee on Legislation printed in the September number of the Journal of the Michigan State Medical Society. The report says.

"A State Department of Education is the one agency of the State which should be best equipped to look into, evaluate and determine the educational qualifications of him who desires to practice a profession or certain other vocations seeking legal recognition.

"Far too much time and effort, with all the accompanying irritations, lobbying, trades, suspicions and so on, are now taken up by the state legislature in enacting legislation relative to licensing or certificating regulations. This type of legislation is concerned with:

1. Amending existing laws which must be continually amended in order to conform with the ever-changing trends in professional education and,
2. With the creating of new laws and new boards of registration for the ever-increasing new professions and trades seeking legal recognition in the form of regulations relative to educational qualifications and to the setting up of special licensing and certificating boards.

"How much more simple and effective it would be to establish a strong State Department of Education and refer to it the functions and powers of licensure and certification for all professions and other vocations. Assuredly, if this is done, future legislatures would have much more interest, time and energy for important and constructive legislation.



"Moreover, the Governor would be spared the vexing problem of making almost innumerable appointments to the many and ever-increasing boards of registration.

"1. The functions and duties of our State Education Department and State Superintendent of Public Instruction are centered on the teaching

profession, its training and certification. This Department of Education, therefore, is regarded as one which is of concern only to the teaching profession. 2. Now, if all the functions and powers pertaining to educational qualification for the professions and other vocations seeking legal recognition were centered in the State Department of Education, this Department would become a much more effective and important agency in the State government.

"This can and should be done without an increase in the State's tax supported budget. Let us refer to the following: The total disbursements of the State of Michigan, fiscal year ending June 30, 1931, for the Department of Public Instruction (administrative) was $123,995.78. The total receipts credited to twelve other licensing and registration boards during this fiscal year were approximately $167,000. Examination and registration fees and annual registration fees which should be paid in by members of each profession or other vocation, combined, should go far toward the support of the State Department of Education."

The procedure necessary for centering the new powers in the State Department of Education is as follows:

"Article XI, Section 2 and Section 6 of the Constitution should be amended in order to establish a strong State Department of Education. In general, the amendment should provide for an increase in the membership of the Board of Education to, let us say, seven or nine, to enlarge the duties and powers of this Board, and to give this Board the powers to appoint a Commissioner of Education who shall serve during the pleasure of the Board.

"The idea of centering thte functions and powers of certification and licensure in a strong Department of Education has been discussed before several groups representing several professions. In general, the reaction has been that a State Department of Education should be set up which should be given all the functions and powers of certification and licensure for vocations which will seek legal recognition in the future and for all vocations now legally established which desire to transfer these functions and powers to the State Department of Education in the future."

HEALTH MAGAZINE IN KANSAS

The first numebr of the popular health magazine, called "Folks," established by the Kansas Medical Society, was reviewed in this Journal of October first, page 1238. How the magazine has been received by the home doctors is told in the following editorial in the September issue of the Journal of the Kansas Medical Society:

(*Continued on page* 1367—*Adv. xxv*)

(*Continued from page* 1366—*Adv. xxiv*)

"Every member of the Society should have received by this time a copy of the new magazine, 'Folks'—a sample copy in a good many instances in which a subscription blank was inserted.

"Advance subscriptions amounting to nearly one thousand were received from members of the Society before the proposition was presented to the House of Delegates, and before the first issue was ready to mail this number had been increased to almost two thousand.

"Not every member of the Society has subscribed. There are quite a good many who have not even subscribed for a copy to keep on the office table. On the other hand, there are a good many who have sent in several subscriptions, some ten, twenty and in one case fifty. But by no means all of these advance subscriptions came from members of the Society or from doctors; a considerable number of them came from nurses and a considerable number also from dentists.

"Members of the Society could easily secure a large number of subscriptions from the people they know in the community. A magazine of this class at fifty cents a year does not require high-powered salesmanship, it practically sells itself. But it is necessary to give the people a chance to look it over and this the members of the Society could do without any loss of dignity or self esteem.

"We have been asking the secretaries of County Societies to send in names of people they can recommend for solicitors. . . According to the list in the society calendar, there are 61 secretaries of county societies, but that list must be very inaccurate for, according to the replies received to our letters, there are only four.

"We trust that no member of the Society will feel humiliated when he is solicited for a subscription to the magazine published by his State Society. That will certainly happen to those whose subscriptions have not been received at the office of publication. Solicitors will all be given the names of those who are always subscribers, and they will be expected to see all the others.

"Getting this magazine started has occasioned a great deal of extra work for the Bureau, and there is still a great deal to be done The extreme gratification experienced on seeing the last of the first issue in the mails was considerably modified by the realization that work must be immediately started on the next issue So far the members of the Society have been very generous in assisting us in getting material and this is and will continue to be the most difficult part of the work. During the next ten months a large number of short articles will be required and they should be furnished by members of our own organization. There is no excuse for waiting to be asked to contribute something, every member should be willing to tell the people something they ought to know."

HERE

is one of the advertisements of The Sugar Institute

THE advertisement reproduced here is one of the series appearing in newspapers throughout the country. In order to keep the statements in accord with modern medical practice, they have been submitted to and approved by some of the leading authorities in the field of human nutrition in the United States. The Sugar Institute, 129 Front Street, New York.

MEAT-COUNTER bargains ARE MORE delicious

WHEN SEASONED WITH

sugar

In cooking meat, the combination of sugar and salt blends tastefully with the meat juices.

EVERY day your meat dealer offers cheap cuts of meat which have an irresistible appeal to your sense of thrift And you can give most of these cuts an *irresistible* taste appeal by seasoning them with sugar

Of course salt should be added to the meat as it cooks, to overcome flatness But the value of adding sugar is that it develops and heightens the flavor of the meat in a way no other ingredient can.

Try a dash of sugar to season pot roasts, braised lamb and veal, stews and meat loaf In boiling corned beef or ham, add a half cup of sugar, more or less, to the water A dash of sugar to a pinch of salt is also a fine seasoning for many fresh or canned vegetables Flavor and season with sugar The Sugar Institute.

"Flavor and season with Sugar"

PUBLIC HEALTH JOURNAL OF CALIFORNIA

The health magazine called *Better Health* was commended by Dr. L. C. Kinney, President of the California Medical Association, whose annual address was abstracted on page 894 of the August first issue of this Journal. The address gave the impression that the health magazine was published by the State Medical Association, and was similar to *Folks,* the health magazine published by the Kansas Medical Society and reviewed in this Journal of October 1, page 1238; but on writing for a copy, we found that it is the official organ of "The League for the Conservation of Public Health," which was founded by Dr. George H. Kress, Editor of *California and Western Medicine,* the official organ of the California Medical Association. The object of the League was to combat an effort to launch state medicine in California through an initiative measure that was put on the ballot at a general civic election. The League accomplished its purpose, but it had demonstrated its usefulness to such an extent that it and the magazine are still continued with considerable financial backing. *Better Health* is about 8 by 11 inches in size, and consists of 32 pages, of which six or eight are given to advertisements. The articles are of a high class from both a scientific and a social point of view. First there are about 20 pages of discussion of compulsory insurance in unemployment that would do credit to a first-class literary magazine, such as *Harper's.*

Next are two pages of editorial comment, on such subjects as paternalism, early signs of tuberculosis, and milk control.

The next three pages are given to popular answers to medical questions sent by lay correspondents, on such subjects as Diet in duodenal Ulcer, *x*-ray for enlarged thymus, and Diathermy.

All the articles are written for "thoughtful" people, and lack the popular features and devices which are ordinarily used to catch the eye of the public. The information contained in the magazine is not second hand, but original, and is unavailable from any other source. It is refreshing to find a popular health magazine that conforms to these standards.

"Vitamins are the little things in nutrition, the metals are the little things in therapeutics."

For Stubborn Coccogenic Affections

Collosol Manganese

(Crookes)

A Stable Preparation Containing Manganese 1-400

Manganese, when injected, increases the capacity of the body to neutralize many endotoxins, the tubercle bacillus, pneumococcus, streptococcus, staphylococcus, etc. (L. E. Walbum). It raises the power of the body to form antibodies (Madsen) and stimulates regeneration of the blood in nutritional anemias (Myers and Beard).

COLLOSOL MANGANESE does not precipitate on addition to blood plasma and therefore gives rise to the minimum of pain, discomfort and untoward reaction when injected intramuscularly. Numerous published reports testify to its value in the treatment of coccogenic affections, particularly furunculosis, boils, acne, etc.

Supplied for injection in boxes of 6 ½ c.c., 1 c.c. and 2 c.c. ampoules

For oral use in 4 oz., 8 oz. and 16 oz. bottles

Full particulars from

CROOKES LABORATORIES, Inc.

145 East 57th Street, New York City

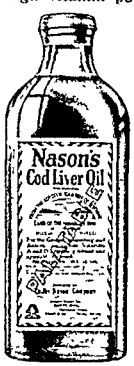
PUBLIC RELATIONS COMMITTEE IN FLORIDA

Several State Medical Societies have committees on Public Relations; but some of the committees confine themselves to legislative activities. That of Florida deals with popular medical publicity. The September Journal of the Florida Medical Association describes a meeting of the Committee on Public Relations at which radio talks were first discussed and a program was developed. The report then says:

"It was considered highly important that the members of this Committee and all speakers that intend to speak over the radio attend a meeting for the purpose of learning the approved methods of talking over a radio, and accustom themselves more or less to them. With this end in view, the next meeting will be held in Gainesville, Thursday, October 8th, which will be well in advance of the first radio talk to be delivered by Dr. Jelks from that station on October 14th.

"The Motion Picture Section was next discussed. The Committee has on file a number of motion picture releases. The feasibility of sending this list to all the county medical secretaries, having their Society discuss the time and which film or films would be acceptable, was discussed. This plan would necessarily consume several months, and very probably would not be satisfactory, therefore, it was moved and seconded that 'this Committee arrange a program and notify each county secretary a considerable length of time in advance the picture or pictures he should expect, asking their societies' cooperation in arranging a program around the film.'

"The next topic brought up for discussion was the Press Bureau. Newspapers, wherever possible, and especially in the larger centers, will be given material to print. These articles will number fifty-two, and one should appear each week. All articles put in the press will be released over the printed signature 'Florida Medical Association,' but to indicate the authority for the same, these articles will be signed by the President of the Florida Medical Association. This signature will remain on the article for the files of the newspapers, but it will not be announced on the printed article.



"The Speakers' Bureau, which also takes in a sub-heading of the Scientific Bureau, was discussed. It was thought that this was too large an undertaking to start synchronously with the other Bureaus, and should be withheld temporarily until the other bureaus were well under way; therefore it was moved and seconded that 'this Committee adopt the three major objectives for this year, 1931-1932, namely, first, Radio, including State and local broadcasting; second, Motion Pictures, and, third, Press.' This motion was carried."

Your Patient needs a Guide!

The woods are full of Cod Liver Oils—a few only are dependable; their quality, purity and vitamin potency approved by qualified medical authorities. Nason's Palatable Cod Liver Oil is one of these.

Recommend or prescribe Nason's by name. Its high vitamin potency and pleasant taste make it worthy of your recommendation and easy for your patient to take.

The handling, preparation, testing and distribution of Nason's Cod Liver Oil from the Lofoten fishing grounds and Nason's own plants in Norway to the finished bottled product is controlled by the Nason organization.

INTERSTATE FRATERNALISM IN COLORADO

The editors of *Colorado Medicine* are promoting fraternalism throughout the states in the Rocky Mountains area, and discuss the subject editorially in the September issue of the Journal, as follows:

"Several significant moves have been made within the last few years toward the promotion of closer relations between the State Medical Societies of the Rocky Mountain region. All give promise of lasting value.

"Perhaps the first was the inauguration of a tri-state meeting in Yellowstone National Park each five years, including the societies of Wyoming, Montana, and Idaho. Not knowing who started this movement, credit cannot be given in this brief statement. The second movement, still in a formative stage, is the Colorado State Medical Society's invitation to Rocky Mountain states to unite in publication of a Rocky Mountain Medical Journal to succeed *Colorado Medicine* (N. Y. STATE JOURNAL OF MEDICINE, Sept. 15, page 1185).

"But this is written not to repeat what has been said before of these plans. It concerns a third plan, not necessarily new, but one which has been neglected sorely for many years and now seems due for a pleasant and profitable revival.

"In this year of 1931, the Colorado State Medical Society and the Utah State Medical Association are exchanging fraternal delegates, each giving prominence on its program to a speaker who will represent the other.

"At Colorado Springs we will have the honor to welcome Dr. Louis E. Viko of Salt Lake City as the representative of the Utah Association. One week earlier, Dr. Glen E. Cheley of Denver will represent the Colorado Society at the Thirty-seventh Annual Meeting of the Utah Association in Salt Lake City. In addition the Utah Association has invited Drs. Robert Levy and Herman I. Laff of Denver as guests of the Eye, Ear, Nose and Throat Section."

MEDICAL ECONOMICS IN CALIFORNIA

The July issue of *California and Western Medicine* contains the following announcement of the plans of the Committee on Medical Economics:

"The Committee on Medical Economics of the California Medical Association was created for the purpose of investigating methods by which medical service, including hospitalization, is now being rendered to the people of California.

"It was understood that the character of the service and the cost to those furnishing it and to those receiving it, where possible, be ascertained. The reasonable ability of the people to pay for medical service, naturally, is an important feature of the investigation.

"This committee gives sympathetic consideration to every suggestion made, but insists that assertions be backed by truth-proving facts. Of one thing the committee is firmly convinced and that is, that the problem of furnishing adequate medical care at a cost that people of moderate means can easily afford varies greatly in different communities within the borders of our own state. This being true the committee urges every county medical society to appoint a local committee to cooperate with the state committee and its subcommittees in obtaining information from all parts of the State.

"These local commitees should investigate and report conditions in their own counties, send reports to the state committee and, above all things, they should refrain from approval of suggested plans until they have been subjected to analytical study and approval by the state society

"This column will be devoted to contributions on the subject, and while the state committee will carefully study every communication, the fact that it is printed here does not mean that the committee either approves or is responsible for it."

OBSTETRICS AMONG THE INDIGENT OF MICHIGAN

The October number of the Journal of the Michigan State Medical Society contains the following editorial:

"The Public Welfare Commission passed a resolution recently to offer the doctors of Detroit who may be interested the sum of $10.00 each for confinements in indigent families. These cases had heretofore been cared for at the municipal hospitals at public expense and at a stated cost of $67.00 each, so that the care included hospitalization as well as the actual obstetric service. The offer is in the way of a temporary measure to aid in civic economy, which is so very necessary in every department in the metropolitan city of the state. This has given rise to considerable discussion pro and contra among the members of the medical profession. Some maintain that it is impossible to attend confinements at this price and to do good work. This argument may be disposed of by the statement that a doctor or any other professional man is presumed to give of their best no matter whether his fee be $10.00 or ten times the amount. In other words the quality of a doctor's work should never depend upon the amount of money he receives. Such is true of but very few other occupations under the sun, but it is true of medicine. There is only one grade of service in medicine and surgery and that is the best that the trained physician and surgeon can render.

"The members of the Welfare Commission have endeavored to do something constructive towards helping out an unfortunate situation, and the proffered solution should not be lightly dismissed. We feel, however, that while the fee may be inadequate, it should not affect the quality of service. The doctor, all things considered, renders more gratuitous community service than any other person. What should be a community service in too many instances has been shelved upon the doctor to render gratuitoush "

ELI LILLY RESEARCH DIVISION

Histories of medicine are replete with romantic accounts of weird beliefs that appear ridiculous in the light of our present knowledge. When Darwin's *Origin of Species* appeared, in 1859, the scientific men of that day were still having controversies on the origin of life. Such men as Pasteur and Koch laid the foundations for many of the brilliant researches that followed their day. The nineteenth century saw many improvements in surgical practice, thanks to anesthesia, antiseptics, and asepsis. Morton demonstrated ether anesthesia in 1846. Ether continues to be a boon to humanity, its benefits more recently improved through the use of sodium iso-amyl ethyl barbiturate, a product of the research division of the Lilly Laboratories, known as Pulvules Sodium Amytal. Sodium Amytal exerts a hypnotic, sedative, and anticonvulsant effect. In surgery its preanesthetic use calms fear and apprehension, allows a quicker induction of inhalation anesthesia, lessens the amount needed, diminishes postoperative nausea and vomiting and when used in conjunction with local anesthetics protects against potential toxicity of the latter.

Pulvules Sodium Amytal have been found of distinct use in obstetrics. Their administration materially shortens the time ordinarily required for complete dilatation of the cervix. The product is also said to have a number of uses in general practice; the correction of insomnia, the production of mental and physical rest in miscellaneous conditions, the control of convulsions, and, in conjunction with morphine, the relief of pain.

Eli Lilly and Company, Indianapolis, Indiana, are offering a liberal trial package of Pulvules Sodium Amytal. Every physician has a use for a preparation of this kind. Requests should be addressed to Department M in care of the company.—See page xiv—*Adv.*

SILVER NITRATE APPLICATORS

The Arzol Chemical Company, Nyack, N. Y. are now making up these applicators conveniently packed in a moisture-proof enclosure, and securely held in position separated from each other, so that only one applicator is withdrawn at a time as needed.

The two inch applicators are packed in units of five, and there are twenty units in a box.

The six inch applicators are packed in units of ten, and there are ten units in a box.

A leather case to hold one six inch unit is given free to the purchaser of the six inch package. This provides a convenient way of carrying these applicators about or as a container for the silver nitrate applicators in the office. —See page xxx—*Adv.*

RECIPE FOR COOKING MEAD'S CEREAL

When cooked according to the following recipe, and served with milk, Mead's Cereal is eagerly accepted by infants:

Place 2 rounded tablespoons Mead's Cereal and 1 cup *cold* water in upper section of double boiler, mixing with fork or wire whip. Place over direct flame for 10 minutes, while stirring. Replace upper section over lower section of double boiler and continue cooking for ½ hour the night before, and ½ hour before serving, stirring occasionally, or, leave double boiler over "pilot" gaslight until morning. This makes a day's supply for the average infant. Number of tablespoons fed is increased from 2 tablespoons, according to age.

For older children, the consistency may be increased by using ½ cup of Mead's Cereal and 2 cups water (2 to 3 portions). Served with cream and sugar, Mead's Cereal deliciously supplies the growing child with protein, fat, carbohydrate, calories and what is more important—*calcium, phosphorus, iron, copper, and other essential minerals.*—See page xv—*Adv.*

VICHY CELESTINES

The Medical Profession will be interested to know that the Vichy Company of Paris has given special consideration to the needs of the individual physician, wherever located, in obtaining supplies of Vichy water for himself and his patients.

In order to facilitate the distribution in this country, the American Agency of French Vichy, Inc., 503 Fifth Avenue, New York, has been appointed Sole Agents for the United States.

The Vichy Company of Paris has expended large sums on improvements recently completed, at the bottling establishment at Vichy, whence the famed natural mineral water from Celestins Spring and also from the Grande-Grille and Hospital Springs is shipped to all parts of the globe.—See page xxiii—*Adv.*

NEW YORK STATE JOURNAL of MEDICINE

PUBLISHED BY THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

VOL 31, NO 22 NEW YORK, N Y NOVEMBER 15, 1931

*A STUDY OF CARDIOVASCULAR SYPHILIS IN PRIVATE PRACTICE

By LOUIS FAUGERES BISHOP, M D, and LOUIS FAUGERES BISHOP, JR, M D, NEW YORK, N Y.

ALTHOUGH many studies of cardiovascular syphilis have been made of hospital and clinical patients, there have been very few studies where the selection of cases has been from a private practice We thought it might be of interest to make the following study The number of cases we reviewed for this work was 3,627, from the year 1918 to 1931 Out of this number we were able to find sixty examples where there seemed little doubt that cardiovascular syphilis was present All of these had a positive serology, with one or two exceptions where the serology had been changed by treatment but here there was little doubt that we were dealing with a true syphilitic cardiac condition It is also a known fact that positive serum reactions are present in eighty percent of cardiac syphilis It is an interesting fact that a little less than two percent of all cardiological patients referred to us had a cardiac lesion of syphilitic etiology We believe this percentage less than a hospital series would be panying definite evidences of neurosyphilis and it is possible that we would have found on more careful neurological observation evidence of neurosyphilis in others Central nervous syphilis is said to be evident in about ten percent of cardiovascular syphilis

It is interesting to note that this study is of a rather higher social strata than would occur in a public hospital or clinic group All of our people were white, with one exception, and all of them were seen in an office practice In this study there were forty-nine males and eleven females a ratio of about 5 1 This male predominance occurs in nearly every study made on cardiovascular syphilis, due probably largely to greater male exposure to syphilis and the factor of greater physical activity

In regard to age, the largest number fell between the ages of forty to sixty years Forty of the sixty were observed during this age period The age seems to be somewhat higher than is usually found in studies of this kind It is also

always been of great interest and we have tried in our series to determine this in as many examples as possible. We were able to do this in about thirty-three percent, as shown by the following rather bizarre figures: Two years, two. Ten years, one. Fifteen years, two. Sixteen years, one. Seventeen years, one. Eighteen years, one. Twenty years, one. Twenty-two years, one. Twenty-five years, one. Twenty-seven years, one. Twenty-eight years, one. Thirty-four years, one. Thirty-five years, one. Forty years, two. Forty-three years, three.

The wide variation between the primary infection and evident cardiovascular involvement can be seen. From these figures it can also be seen that the process usually remains latent or unrecognized in our series for about 17-18 years.

The result of the study of the symptoms of our group of cardiovascular syphilis showed the rather classical findings. It should be emphasized, however, that cardiovascular syphilis is often symptomless. Pain and dyspnœa were the most frequent presenting symptoms and these occurred either alone or together. It was often noted that the dyspnœa was paroxysmal in type.

TABLE IV

PRESENTING SYMPTOMS

Pain	22
Dyspnoea	15
Pain and Dyspnoea	6
Palpitation	7
Fatigue	2
Cough	1
Throbbing in Neck	2

An electrocardiographic study was made with the following findings: Normal mechanism—Thirteen. Left axis deviation, without abnormality—Twelve. Left axis deviation, with abnormality—Twenty-one. Right axis deviation—Four. Auriculo-ventricular block—Seven. Intraventricular block—Two. Complete heart block—One. Ectopic auricular contractions—Four. Ectopic ventricular contractions—Six. Auricular fibrillation—Four. Sinus tachycardia, without abnormality—Seven. Sinus tachycardia with abnormality—Eight. T-wave negativity, Lead I—Nine. Lead I and II—Two. Lead II and III—Three. Lead I, II and III—Two.

From these findings it is interesting to note that there is a relatively large number with no abnormal electrocardiographic findings and that almost every form of electrocardiographic curve can be found in a lesion of the heart due to syphilis. As would be expected there is a large number with left axis deviation and also a relatively large number with T-wave negativity. In this connection one must not forget that some of these had received digitalis. Our feeling is that there is no particular lesion shown in the electrocardiogram that is characteristic in any way of heart disease due to syphilis but we were interested to find out exactly what our electrocardiographic findings would be after a careful analysis. There seems to be also more arrhythmias present in our study than in most electrocardiographic studies on this subject.

In nearly all of our group we had taken a six-foot *x*-ray plate of the heart, whereas, we were well aware that this *x*-ray study would not be in any way conclusive we were interested to find out what a re-study of these plates would reveal. With the aid of a roentgenologist, Dr. Ramsay Spillman, we reviewed fifty-five available plates with the following results: There were twenty-four plates, or nearly fifty percent, where there was no *x*-ray evidence of cardiac or aortic pathology. Cardiac hypertrophy with manifest aortic enlargement was present in eighteen. In two examples the aorta was widened with cardiac hypertrophy. In four there was a widened aorta alone, and in one the aorta was quite sclerotic and elongated with cardiac enlargement. There were five aneurysms, four sacculated and one fusiform.

From this summary of the *x*-ray the most striking point is the number with no *x*-ray evidence in the six-foot plate.

The fact that many had had some treatment before coming to us leaves the question of the

study of the effect of treatment entirely unsatisfactory It is true, however that we had some extraordinary responses to specific treatment where the disease had not been previously discovered or treated It is not our purpose in this study, however, to go into the treatment except to say that we have followed what has been fairly well agreed upon as being the best method of handling cardiovascular syphilis Most of our people received courses of mercury or mixed treatment and certain selected ones were given small doses of salvarsan Nearly all of these received *the benefit of constant medical observation* and the best possible nursing and environmental care This is mentioned because if any group of heart diseases due to syphilis is to do well it should be those who have the benefit of constant medical observation We often had the advice of syphilographers

It is relatively easy to classify post-mortem study lesions of cardiovascular syphilis but a clinical classification is somewhat difficult It was our opinion that this series had the following objective findings, or physical signs

There were twenty eight with aortic insufficiency Seven with definite aneurysm of the aorta Ten had an aortic systolic murmur Fourteen had no objective findings and one had evidence of what was considered a mitral stenosis and insufficiency, with syphilitic myocarditis The reason this was included was that previously undiscovered and untreated constitutional syphilis seems to have led the attack of broken compensation and compensation was restored when the syphilitic desease was treated Rheumatic pathology of the heart is so extensive that we cannot prove whether there was any organic specific lesion of the heart or aorta However, the extraordinary response to treatment might lead us fairly to infer that there was a specific influence acting on the heart muscle

Of the sixty examples which we have included in our study we were able to find information in forty-eight Of this total number, twenty-nine had died, or nearly sixty percent We then attempted to find out what the average duration of life was from our clinical classification

In seventeen with aortic insufficiency the average length of life, after being first seen by us was two years and ten months In six with definite aneurysm of the aorta the average length of life, after being first seen, was two years The average length of life here is misleading because five of the six with aneurysm lived only an average of six months Of the three examples having only objectively an aortic systolic murmur the average duration of life was two years and nine months

The above were all ambulatory when first seen and they were followed up until the time of death and most of them died at home rather than in a hospital There are at the present time nineteen in this series who are alive which in our classification were grouped as follows

Aortic insufficiency, five Aneurysm of the aorta, one Aortic systolic murmur, two Syphilitic myocarditis, one Unclassified, ten

TABLE VI
CLASSIFICATION

	Cases	Unknown	Dead	Alive
Aortic Insufficiency	28	5	18	5
Aneurysm of Aorta	7		6	1
Aortic Systolic Murmur	10	2	4	4
Mitral Stenosis and Insufficiency	1			1
Unclassified	14	3	1	10

In a recent study, Moore and Danglade found that the average duration of life in their series of treated patients from the onset of symptoms to death was two years and eleven months, which agrees very closely with our results in private practice Their study included fifty-three cases taken from the Syphilis Division of the Medical Clinic, Johns Hopkins Hospital

The conclusion we can make from this study is that cardiovascular syphilis presents very much the same problem in private practice as it does in hospital and clinic work and we feel it is of interest that our findings in the study of our group agree so closely with studies made on hospital and clinic groups

BRANCHIOGENIC CYST

By LEO SCHWARTZ, JR., M.D., NEW YORK, N. Y.

BRANCHIAL cysts, while not medical curiosities, are of sufficiently infrequent occurrence to remain interesting.

The following case represents a typical example. A bibliography is appended, a perusal of which will familiarize one with the many interesting features of this condition.

E. F., a young woman, 23 years of age, was referred to me for examination with the suggestion that a swelling present in the left side of the neck was possibly due to an enlarged lymph node due to infected tonsils.

History of Case—She had first noticed a swelling in the left side of the neck about three years previously. It had gradually increased in size until it had reached present proportions. At no time had there been any pain. She had often had attacks of sore throat and in the last few years had had peritonsillar abscesses on the left side incised. On several occasions, the occurrence of these abscesses had antedated the appearance of the swelling.

Examination—There was a swelling in the left side of the neck extending from the angle of the jaw to the thyroid cartilage anterior to the sternocleidomastoid muscle (Fig. 1). It was about the size of a small tangerine, was fluctuant and not attached to the skin. The sternocleidomastoid muscle overlapped the mass. There was no pain nor redness present. It was not translucent.

The tonsils were hypertrophied and diseased.

Examination of the nose showed a polypoid right middle turbinate which was also very turgescent. There was a right chronic purulent otitis media with a perforation at the lower posterior quadrant through which a polyp protruded. A malodorous purulent discharge had been present for 12 years.

The patient was advised to submit to an operation for removal of the tonsils due to the repeated attacks of peritonsillar abscesses and was advised that at a later date the tumor in the neck could be removed.

October 20, 1930, tonsillectomy and adenoidectomy performed under general anesthesia. The left tonsil was removed with difficulty due to the unusual scarring of the fossa. A large adenoid mass was also removed.

On January 15, 1931, the original mass not having diminished in size, the patient was sent to the hospital and under local infiltration anesthesia of 1% novocain, a transverse incision was made over the mass and with careful blunt dissection the cystic sac with some of its contents was removed in toto. The cyst wall ruptured during the dissection and the fluid content, which was of a creamy consistency and in appearance not unlike pus, was under sufficient pressure to project a stream upward for several inches. Some of this escaping fluid was saved for chemical and microscopic examination. The sac extended downward to the carotid sheath but did not extend between the vessels enclosed therein, and fortunately for the patient a complete removal was possible without damaging the important structures.

Pathological report by Dr. Julius Pincus, of the Joint Diseases Hospital.

Gross—Specimen consists of a cystic mass received at laboratory opened up. Grossly, cyst would be about the size of a walnut when filled with secretion. At one pole a small whitish area of tissue is seen. Cyst fluid is milky white secretion and contains fatty acid and cholestrin crystals on chemical examination.

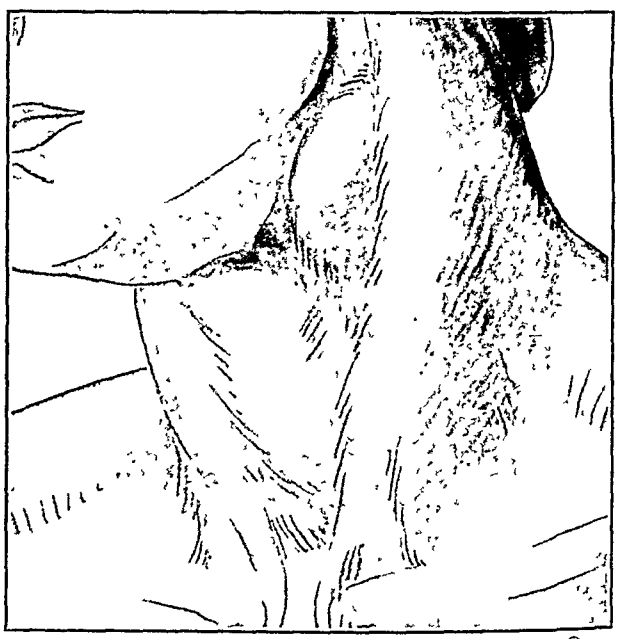

FIGURE 1

Artist's drawing showing location and relation of cyst to sternocleidomastoid muscle and topography of neck.

Microscopic—Internally the cyst is lined by stratified squamous epithelial cells (Fig. 2). Beyond this lining is seen fibrous tissue stroma containing numerous small and large blood vessels and the greater part of the stroma is filled with lymphoid tissue with follicle formations surrounded by a fibrous tissue capsule (Fig. 3). No malignant changes were noted. These pictures illustrate the classical text book description of a branchiogenic cyst.

Diagnosis—Branchiogenic Cyst

Comment—It is possible that this cyst at one time communicated with the tonsillar fossa and

FIGURE 2

Low power photomicrograph of section of cyst wall showing lumen and stratified squamous epithelium lining

FIGURE 3

Section showing characteristic lymphoid follicle in stroma of cyst wall

due to the cicatrization that took place following the abscesses, the opening was obstructed giving rise to the subsequent mass formation in the neck. This would account for the obliteration of the communication between the cyst and the opening within the mouth if there had been any communication previous to operation.

The patient made an uneventful recovery and at this time shows no recurrence.

TREATMENT OF INFECTIONS OF THE CENTRAL NERVOUS SYSTEM BY FORCED SPINAL DRAINAGE*

By GEORGE M. RETAN, M.D., SYRACUSE, N. Y.

THE acute infections of the central nervous system are of a serious nature. Septic meningitis and tuberculous meningitis are nearly always fatal. Encephalitis, poliomyelitis, cerebro spinal meningitis and syphilitic meningitis give a varying mortality with our present method of treatment. Many of the recovered cases develop serious and permanent sequelae. I believe one is justified, therefore, in using any type of therapy that offers some prospect of improving our results in the treatment of these diseases.

Forced spinal drainage must not be confused with continuous spinal drainage. Theoretically, forced spinal drainage is sound. My work with this method has convinced me that it is safe. This treatment offers a further advantage in that it can be combined with other types of treatment. Any serum that may be useful in the individual case can be given in conjunction with it.

Kubie has laid the ground work for this type of therapy by his experiments with animals.

Under normal conditions, water and certain salts pass through the capillary walls into the interstitial spaces, and from the interstitial spaces into the capillaries. This takes place by the process of osmosis. If the concentration of salt is greater in the capillary, the flow is from the interstitial spaces into the capillary. If the salt concentration is less in the blood stream, the flow is from the blood stream into the fluid spaces surrounding the capillary. The force causing this interchange is called osmotic pressure, and depends on the concentration of salts in the solution. The normal osmotic pressure of the blood is that of an aqueous solution of 0.9 per cent of sodium chloride. A solution of greater concentration than 0.9 per cent of sodium chloride is called a hypertonic solution; a solution of less than 0.9 per cent is called a hypotonic solution. The permeability of the capillary wall may vary in different organs and in the same organ under different pathological conditions. There is evidence that in acute inflammation of the tissue the permeability of the capillary wall is increased.

There are certain hydrostatic pressure factors that influence this fluid interchange. These pressure factors need not be discussed in this paper.

In case a hypotonic solution is injected into the blood stream, there is a flow of fluid from the blood stream, through the capillary walls, into the surrounding tissues.

The action of such a solution on the central nervous system is shown in the diagram (Fig. 1) The capillaries in the cord are represented by (C). Since the blood has been made hypotonic by an injection of 0.45 per cent sodium chloride solution, there is a flow of fluid from the blood stream of the capillary into the intercellular spaces (I). The fluid flows through the intercellular spaces to the subarachnoid space (S). From the subarachnoid space the fluid is drained from the lumbar needle.

Kubie has shown that there is some hydration of the tissues of the central nervous system as a result of the intravenous injection of a hypotonic solution, provided the subarachnoid space is not drained. (Figs. 2 and 3). If the subarachnoic space is drained no hydration takes place.

Referring to the principles of osmosis we can conclude that in case a hypotonic solution is slowly injected into the blood stream, the osmotic pressure in the capillaries causes the fluid to flow from the blood stream into the perivascular spaces. If the fluid is continuously drained from the subarachnoid space, there is no opportunity for osmotic equilibrium to be established. The washing of the depths of the inflamed area can be continued as long as seems desirable. There is evidence that the flow is greater in the inflamed areas, possibly in proportion to the inflammation.

The most effective method of making the blood hypotonic is by injecting a hypotonic solution into the blood stream. A 0.45 per cent solution of sodium chloride was used in the treatment of these cases. The solution must be injected slowly, not faster than one liter in an hour. The intravenous injection of this solution is essential. Plain water given in quantities by mouth or rectum is a further aid. Kubie concludes from his animal work that "If free escape of cerebro spinal fluid is allowed, the injections produce little rise in intracranial pressure and no recognizable hydration of the tissues of the central nervous system."

The present treatment of acute preparalytic poliomyelitis leaves much to be desired. There is no positive clinical evidence that the intraspinal injection of human immune serum is of any benefit. The theory upon which this treatment is based depends on the following fact: When human immune serum is mixed with polio virus and injected into monkeys, the monkeys will fail to contract the disease. Immune serum injected into the subarachnoid space does not come into contact with the lesions of polio in the anterior horn cells. It may neutralize the virus in the spinal fluid and this may be of some slight benefit. Whether we believe that this treatment is of benefit or not, we are faced with the fact that certain patients so treated die, and a varying percentage develop paralysis.

Poliomyelitis: The pathology of poliomyelitis lends itself peculiarly well to forced spinal drain-

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 3, 1931.

age The first notable change in the central nervous system are a marked hyperemia of the meninges and a collection of small mononuclear cells in the perivascular lymph spaces This process rapidly extends into the cord itself Here is noted the same perivascular collection of mononuclear cells (Fig 4) An oedema develops in the cord The oedema affects the gray matter more than it affects the white matter so that one section the gray matter projects above the level of the white matter Often minute hemorrhages are found Oedema, hemorrhage and cellular exudate are of vascular origin and this is the reason the anterior horn cells are more particularly involved

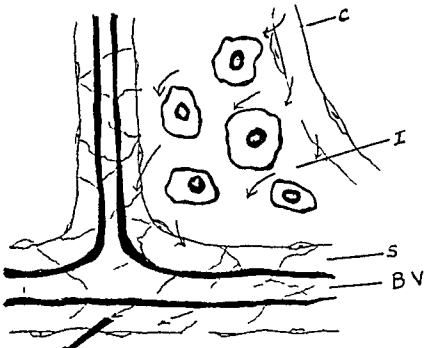

FIGURE 1

Diagrammatic representation of a section of the spinal cord illustrating the flow of fluid from the capillary through the tissue to the subarachnoid space

What role the virus plays in the destruction of the nerve cell has not been determined Possibly there is some toxin in the perivascular spaces which has a direct action on the nerve cell Pressure from the oedema may also be a factor in devitalizing the nerve cell It is, however, not reasonable to believe that this pressure alone is responsible for the destruction This type of cell degeneration is not met with in other diseases or conditions causing oedema of the cord, such as general anasarca

Since it has been shown by Kubie that we are able to wash the perineural spaces continuously by the use of a hypotonic solution and that this fluid can be drained from the body, is it not reasonable to believe we can prevent damage to the nerve cells by making use of this method? If the virus of poliomyelitis exists in the perineural

FIGURE 2

Left Undilated central canal from drained animal

Right Tremendously dilated central canal from undrained animal

spaces it is possible to wash it out of these spaces. One can demonstrate in the spinal fluid the mononuclear cells which have been washed from the perivascular spaces.

Case Report: On November 4, 1930 I saw a girl, age 9 years, who had been exposed to a case of poliomyelitis. She gave the following history:

November 3rd this patient had been perfectly well. She had spent the afternoon riding horseback with her mother and had gone to bed without complaint. The nurse said she had been restless between two and four on the morning of the fourth. At four o'clock she asked to void and then complained of pain in her back and neck. She was unsteady in the bathroom with her legs trembling and shaking. She continued to be restless in her sleep and awakened at 7:15 unable to bend her neck. She was seen at eight o'clock by Dr. Morrow who found her temperature 99. Rigidity of the neck and back was present on attempted flexion. There was a positive Kernig and a tremor of the hands.

I saw the child at 11:30 A.M. Her temperature had arisen to 102.2 —pulse 140. Dr. Morrow found that she had gotten rapidly worse since he had examined her at 8 A.M. The rigidity of the back and neck as well as the tremor had increased. There was pain on attempting to flex the neck. There was a slight redness of the throat. The abdominal and knee reflexes were sluggish. Physical examination was otherwise negative. The patient was taken to the Syracuse Memorial Hospital where a lumbar puncture was done. The fluid was under slightly increased pressure with a cell count of 739. These cells were over 90% polynuclears. She was drained continuously for 27 hours and 45 minutes. The drainage was forced by the intravenous injection of 1000 c.c. of 0.45% NaCl solution. 30 c.c. of human immune serum was added to this solution (See Chart).

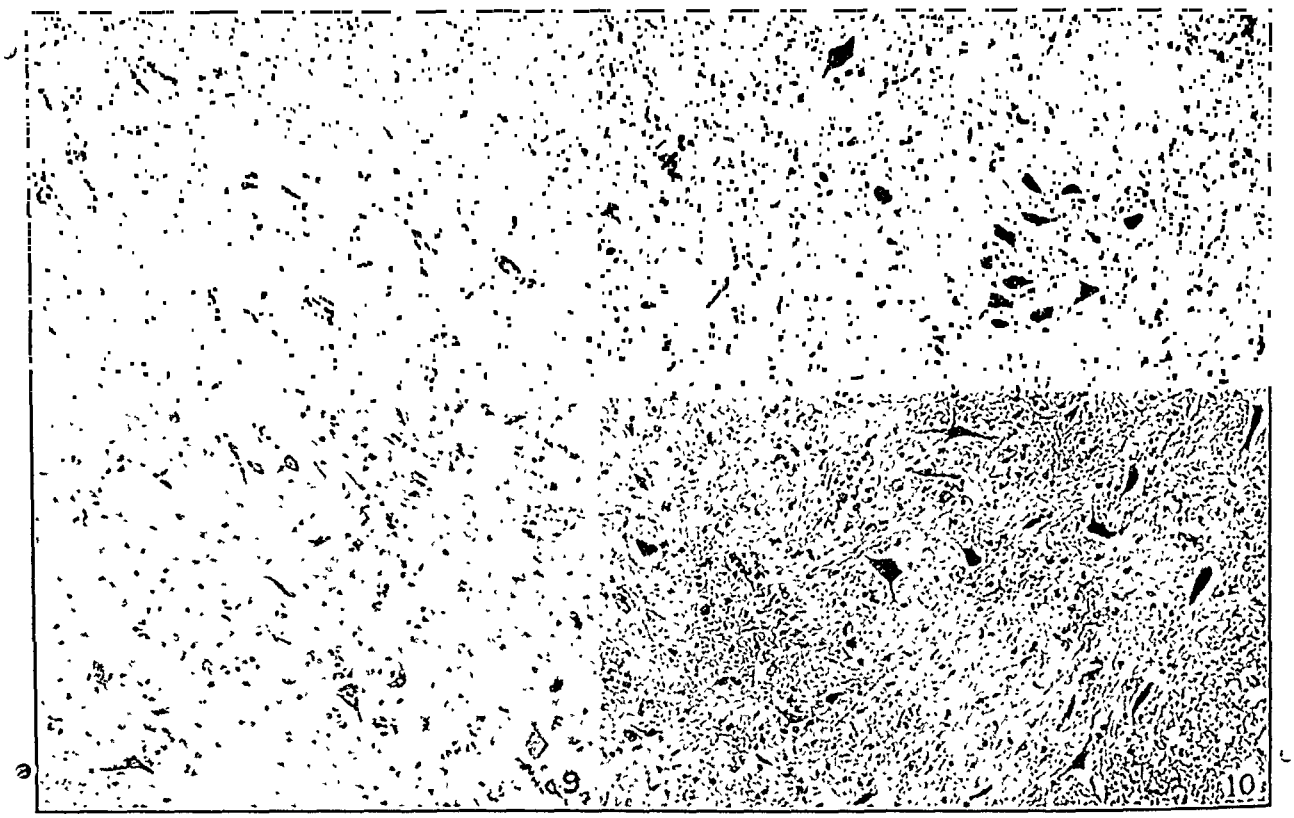

FIGURE 3

Reproduced from "Intracranial Pressure Changes in Health and Disease," work of Kubie. "Brain," Vol. 51, Pt. 2, p. 244, 1928.

Left: Undistended perineuronal spaces from drained animal.

Right: Tremendously distended perineuronal spaces from undrained animal.

When the hypotonic solution was injected, the character of the cells changed abruptly from 90% polynuclears to 80% mononuclear cells. The cell count also increased from 38 cells to 174 cells.

This patient recovered without at any time showing any paralysis or muscular weakness.

Encephalitis: Acute encephalitis is a serious disease in infancy. The mortality is high. Those cases beginning with convulsions are especially

serious The recovered cases usually develop residual symptoms There is no effective and accepted treatment for the acute stage of this disease

Case Report Girl baby, age 11 months seen June 18, 1930 During the afternoon the baby had developed a temperature of 102 which arose at 11 P M to 105 4 At 12 P M the baby developed convulsions These convulsions were terrific—tonic over the whole body with clonic twitching of the left arm and leg There was a violent twitching of the eyeballs toward the right The baby was in a deep coma Inhalations of ether failed to control these convulsions

The spinal fluid was clear but under increased pressure Cell count 7 cells The patient was given continuous spinal drainage for 47 hours The drainage was forced by the intravenous injection of 1000 c c of 0 45% NaCl solution Murphy drip of 400 c c of distilled water was given and 375 c c of water by nasal drip 247 c c of spinal fluid was obtained

Very soon after the treatment was begun the spinal fluid became haemorrhagic and continued to be haemorrhagic throughout the 47 hours of drainage

During the drainage the baby improved The convulsions stopped and later the twitching of the eyeballs The baby had developed a flaccid paralysis of the left leg which was evident as soon as she came out of her coma This was not complete for at times there was some movement of the leg

Following the drainage the baby seemed lethargic She slept, could be aroused to take her feedings The night of the third day the temperature which had remained under 100 during and after the drainage, arose to 104 and convulsions again developed These were promptly relieved by a second drainage which was continued for 20½ hours We obtained 114 c c of haemorrhagic fluid We gave 1000 c c of 0 45% NaCl solution into the vein—450 c c of distilled water by Murphy drip and 200 c c by nasal drip

Before this second drainage the patient had developed a transitory ptosis of the left eyelid and nystagmus The left leg was still partly paralyzed but had improved from its previous condition She had also developed spasm of the extensors of the left arm

Following the second drainage she was greatly improved, sat up in bed and waved to her parents The temperature was normal

During the following week her temperature remained normal and there was a gradual improvement of the left arm and leg At the end of the week the arm and leg were entirely recovered The day following the second drainage cisterna puncture revealed a fluid containing tiny prune colored particles of clotted blood

The baby has remained perfectly well There are no residual symptoms

Septic Meningitis There are possibilities of curing certain cases of septic meningitis by forced spinal drainage The following conditions are necessary for success The original source of the infection must be drained The case must be treated early before a plastic exudate forms on the brain These plastic exudates act as secondary foci The drainage must be continued for

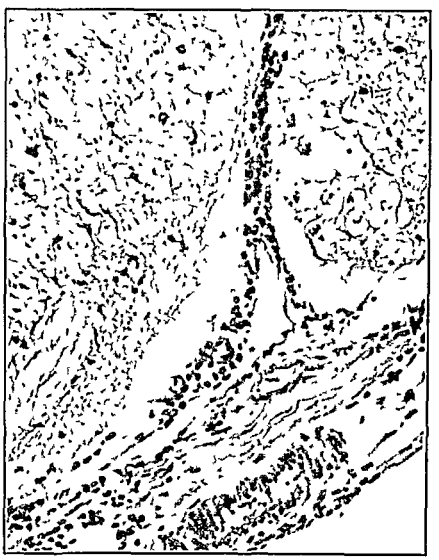

FIGURE 4

Section of spinal cord from a case of poliomyelitis showing perivascular infiltration of mononuclear cells

at least twenty four hours after the spinal fluid count becomes normal

Case Reports I have treated three cases none of which met these requirements One case of about five days duration secondary to an orbital infection (Streptococcus haemolyticus) showed no improvement with forced drainage Autopsy showed a large plastic exudate on the right frontal lobe with pus partly walled off—really a localized brain abscess

A second case —Pneumococcus type II—secondary to an ear infection The middle ear was drained but not the mastoid There was no improvement with treatment—history indefinite as to onset The original spinal fluid cell count was over 4000

The third case one of Streptococcus Haemolyticus followed mastoid Mastoids drained—treat-

ment instituted about fifty hours from onset. The patient was given two liters of 0.45% NaCl solution into the vein and drained for eight hours. During this period the patient showed considerable clinical improvement. He came out of a deep coma but later lapsed into coma and died. Autopsy revealed a plastic exudate on one of the frontal lobes. There was no hydrosis of the brain or other organs in the gross or microscopic specimens.

Leighton reports three recoveries in ten cases. These cases were treated by continuous drainage and lamienectomy. Lamienectomy allows of better drainage since there is often difficulty in keeping the needle in the canal continuously for a long period of time. Kolmer reports two recoveries in eighteen cases of septic meningitis. He used intra carotid injections of sera and solutions with intermittent spinal drainage.

Syphilitic Meningitis: Syphilitic meningitis in infancy causes idiocy, hydrocephalus and various types of paralysis.

Baby S.—five months old—colored—entered the hospital July 19, 1930 with signs of acute meningitis. There was a rigidity of the neck and back and bulging fontanelle. The spinal fluid was under a pressure of 22 m.m. mercury, with a cell count of 90, 98% mononuclear cells. Globulin slightly increased. Spinal fluid and blood Wassermanns showed complete fixation.

The treatments given were as follows: Sulpharsphenamine intramuscularly 0.2 gms. every five days for ten doses, with daily inunctions of mercury. Following this bismuth salicylate was given once a week until September fourth.

At this time the spinal fluid gave a normal cytology. No meningeal symptoms were present, but the head was enlarging about twice its normal rate. There was a bulging fontanelle. Both blood and spinal fluid were still positive to the Wassermann reaction.

September 18th:—Forced spinal drainage for 24 hours using 1000 c.c. of 0.45% NaCl solution containing 0.2 gms. of neoarsphenamine. 271 c.c. of spinal fluid was obtained.

October 14th—Forced spinal drainage for 18 hours. 1000 c.c. of 0.45% NaCl solution containing 0.4 gms. of neoarsphenamine was given into the vein. 200 c.c. of spinal fluid was obtained.

November 11th—Forced spinal drainage for 25 hours. 300 c.c. of 0.45% NaCl solution was given into the vein with 0.2 gms. of neoarsphenamine. 184 c.c. of spinal fluid was obtained.

December 31st—Forced spinal drainage for 32 hours. 1000 c.c. of 0.45% NaCl solution containing 0.9 gms. of neoarsphenamine was given into the vein. In addition 225 c.c. of water was given by nasal drip. 245 c.c. of spinal fluid was obtained.

Since December 31st the spinal and blood Wassermanns have remained negative. The case is still under observation and there is no evidence of the activity of the disease. Since the first drainage the head has grown at a normal rate.

It is possible that when arsenicals are introduced into the blood stream with a hypotonic solution, a larger percentage of the arsenic might be drained through the lesions of the central nervous system.

Summary: It is evident that much more clinical and experimental data will need to accumulate before we can draw any conclusions as to the efficacy of forced spinal drainage in the treatment of infections of the central nervous system.

The treatment is theoretically sound.

The case of poliomyelitis seemed like an acutely fulminating case. We can not conclude that the treatment was responsible for her recovery for many cases of poliomyelitis recover without any treatment.

Forced spinal drainage should not be confused with continuous spinal drainage. Continuous

spinal drainage is of questionable value in the treatment of preparalytic poliomyelitis although it has been used successfully in certain cases of septic meningitis The abrupt change in the cytology of the spinal fluid of the poliomyelitis case coincident with the intravenous injection of the hypotonic solution presents further evidence that we were washing fluid through the lesions

The improvement of the encephalitis case during the drainage was most impressive

My work with this method of treatment has convinced me that it is a safe procedure

BACTERIOPHAGES AS A HELP IN THE TREATMENT OF INFECTIONS IN CHILDREN*

By WARD J MacNEAL, M D, NEW YORK, N Y

From the Department of Pathology and Bacteriology New York Post Graduate Medical School and Hospital
These studies have been supported by a grant from the Josiah Macy Jr Foundation

SINCE the pioneer observation of transmissible autolysis of bacteria by Twort[1] in 1915 and the subsequent extension of such observations especially by d'Herelle[2] there has been produced an extensive literature dealing with the general subject of the bacteriophage phenomenon and its possible importance in infectious diseases The phenomenon itself is one of peculiar interest in general biology and its observation has introduced an uncertainty in regard to minute forms of life, which has been compared to the influence of the discovery of radium upon the elementary ideas concerning molecular and atomic structure With these more theoretical conceptions of general biology we are not at present concerned

D'Herelle's classical example of the phenomenon may be observed as follows Take a small amount of stool from a patient convalescing from bacillary dysentery, suspend it in broth and filter through a porcelain filter to obtain a bacteria-free filtrate Add a drop of this filtrate to a young broth culture of the dysentery bacillus and place the culture in the incubator In a few hours it is diffusely clouded with bacterial growth but soon thereafter, ordinarily in eight to twelve hours the broth becomes perfectly clear and it may no longer be possible to demonstrate the bacteria in it either by microscope or culture A drop of this clear liquid added to a new culture of the dysentery bacillus brings about a repetition of the phenomenon and this may be repeated indefinitely Obviously the agent which causes this solution of the bacteria is being reproduced in increasing amounts Its precise physical chemical or possibly biological nature is not clearly understood It is the bacteriophage for the dysentery bacillus

Analogous filterable agents have been found which will cause dissolution of other bacteria, such as the typhoid bacillus, the colon bacillus, the bacillus of green pus, the golden staphylococcus In fact there is reason to think that the phenomenon may be quite general for all the bacteria and that persistent search may be rewarded by the discovery of a bacteriophage for each pathogenic microbe or at any rate for many of them The tubes and culture dishes here shown illustrate the phenomenon as it occurs in broth cultures and on agar plate cultures of the colon bacillus and the staphylococcus

From such examples of complete destruction of the bacteria one may gain the impression that the bacteriophage always destroys the bacteria against which it is potent Such, however, is not the case Frequently one may observe the apparently complete clearing of the broth culture only to have it become cloudy again after twenty or more hours because of the growth of bacteria which, although tainted by the bacteriophage are nevertheless sufficiently resistant to it so that they continue to survive and multiply in its presence The bacteria of such secondary growth show peculiarities of individual shape and structure and in colony form as well as alterations in virulence, which have furnished themes for an extensive literature Furthermore, one observes that various environmental conditions influence the outcome of the struggle for existence on the part of the bacterial cells in the presence of the bacteriophage Significant contrasts are readily obtained by incubating identical mixtures at different temperatures In our laboratory, experiments carried out by Miss Frisbee[3] have revealed a remarkable influence exercised by the hydrogen ion concentration of urine in the bacteriophagy of the colon bacillus in urine The significance of these results for the treatment of infections of the urinary tract is obvious Somewhat analogous experiments by Miss Applebaum[4] have revealed in influence ex-

* Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse N Y June 3 1931

such as a large spur on the septum with enlarged middle turbinates, producing bad ventilation of the ethmoid region, will be a predisposing factor, always worth noting. A slight thickening of the membrane over the posterior ethmoid and sphenoid region with a shiny, oedematous appearance is often present, or the membrane may appear much redder than normal. The nasopharynx will often show a granular tract on one or both sides extending under the posterior pillar. This will indicate a chronic discharge from the sinuses and although scarcely noticed by the patient will often be the most positive evidence of sinus infection that one is able to obtain. Once a tentative diagnosis has been made, treatment will usually be surgical. If the eye lesion is not severe and if the oculist thinks there is no danger in a delay of a week or two, intranasal treatment may be tried and the eye carefully watched. In retrobulbar neuritis it is not usually advisable to wait very long, but in young subjects whose regenerative powers are very strong a good result may be obtained even though the process has been going on for some time. In older patients it is important to remove the cause as quickly as possible and one should not wait very long before resorting to surgery. In the series of 44 cases reported by the late Dr. E. S. Thomson[1], in which the various eye affections were associated with infected sinuses and tonsils, operative procedure was carried out almost as soon as the diagnosis was made and the earlier the operation the better the results. Dr. Thomson had a large experience in this field and his conclusions were that sinus disease caused iritis, cyclitis, retinitis, and choroiditis in almost as great frequency as it caused optic neuritis. He also stated that the diagnosis of the casual relationship is so difficult for the rhinologist in many cases that it must remain for the ophthalmologist to decide when the sinus operation should be done.

Infection of the lacrymal sac may be secondary to nasal infection and will not respond to treatment till the intranasal condition has been treated. Obstruction in the nasal duct can also occur from inflammation inside the nose extending into the duct. Occasionally one sees the opening of the duct in the inferior meatus occluded from a swollen or polypoid inferior turbinate. Removal or cauterization of a part of the turbinate may help this condition but the results are not always satisfactory. The West operation for removal of an old chronic, suppurating sac by the intranasal route is a well-devised procedure but is rather difficult technically and unless thoroughly done is not likely to provide much benefit to the patient.

When the tonsils are suspected as a source of infection the diagnosis can usually be made with quite a positive degree of certainty. Any tonsil containing thin, liquid pus which can be demonstrated on slight pressure or suction is an obvious focus and should be removed at once if eye symptoms are present. There is, however, a possibility of a tonsil being the cause of mischief where the infection is not so obvious. One may find it very difficult to demonstrate any pathology in a small, buried tonsil stump and yet it may be the real source of the infection. I have advised the removal of such tonsils on speculation on several occasions and found much more than I had suspected. A history of an attack of tonsilitis at any time during the patient's lifetime may be all the evidence obtainable in some cases.

The late Dr. Leon White[2] who did a great deal of work in the relation of sinusitis to eye infections came to the conclusion that tonsils and teeth were more often the original cause of such infections than the sinuses. My experience has been more with the cases with sinus pathology but the cases from other causes may have been sent to other specialists so I cannot draw conclusions in regard to their relative frequency.

I now wish to report briefly three cases which will best illustrate the observations of this paper:

The first was a case of bilateral retrobulbar neuritis. A girl aged 13 years, brought to me the 15th of June, 1926, had started to lose vision in April in the left eye, and three weeks previous to the time I saw her the right eye began to fail. Her father was a doctor and an extensive investigation had been made in a large city. Finally, a diagnosis of suspected brain tumor had been made. They were then on their way to Boston to consult Dr. Cushing. His visit to me was to get my recommendation for a New York oculist. On inquiring about the case, I found out she had had a bad attack of influenza a month before the onset of the eye trouble. I asked him to bring the child to my office and let me see her. I found she had some mucoid discharge in the back of her throat and some congestion in the posterior ethmoid and sphenoid region with a thickened septum. I referred her to Dr. E. S. Thomson and he reported by telephone at once that she had a double optic neuritis with 20/200 in the left eye and 20/40 in the right, and said it looked very much like a sinus condition. With this evidence and my own findings I decided to open the ethmoids and sphenoids on both sides. This I did on June 16th, doing a submucous, complete exenteration of ethmoids on both sides and opening both sphenoids. In forty-eight hours the sight in the right eye was normal and three days later the sight in the left eye, the bad eye, was normal. She has remained perfectly well ever since. This case illustrates the remarkable regenerative power of the nerve in a young patient. It also illustrates the lack of recognition on the part of the profession of these important pathological relations as this patient's sinus condition had not been suspected.

The second case was a man of 48 who had lost the sight of his left eye from an accident in boyhood. Over a year previous to the time I saw him

his vision in the right eye had begun to fail He had gone through an elaborate investigation during that time having spent several months at the Mayo Clinic and having seen many of the best specialists in the country His eye lesion was a choroiditis with recurring hemorrhages in the macular region, the vision failing somewhat after each attack He gave a history of an infection in the right antrum fifteen years before This had been irrigated three times a week for six weeks and pronounced cured During the time of this antrum infection he had run a temperature and had sweats After the onset of his eye trouble he had had this antrum irrigated several times with no discharge found and no improvement in his eye condition The x ray at this time showed some cloudiness of the right antrum The clinical examination showed practically nothing Tonsils had been thoroughly removed and on irrigation of the antrum the return flow was perfectly clear In view of the rather desperate prospects and relying on the past history of such an antrum infection I advised a radical antrum operation The oculist who sent him to me thought my evidence rather flimsy and was very sceptical of my supposition that an antrum infected fifteen years before could have anything to do with the present condition I referred to the chronicity of syphilis and remarked that other infections under some conditions could last just as long After much persuasion I was allowed to open the antrum intranasally He showed no improvement after this, in fact I thought he was worse and was more or less septic for some time I felt certain that I had merely stirred up a focus and had not removed it He went away and continued slowly to lose his vision A year later he was sent back to me by Dr DeSchweinitz His vision was then 18/200 and this time I was able to persuade him to have a radical antrum done At the operation, I found a mass of granulation tissue on the floor half an inch thick but no free pus I cleaned this out and he made a steady recovery, his vision coming back to 20/40 in two months

The third case was a young man of 26 who had suffered from frequent recurring attacks of iridocyclitis, the first attack occuring seven years previous to the time I saw him He had had his tonsils removed and this gave him a respite from the attacks for nearly three years When the attacks returned, his antra were operated on, a double Caldwell Luc being done on both sides, but he got no result and during the past year his condition had been gradually getting worse in spite of the fact that he had been sent to Arizona for three months His ethmoid sinuses had been examined by several specialists but were considered normal I examined him several times and always found slight œdema of the membrane with increased redness over the ethmoid area On the advice of Dr E S Thomson, I opened the ethmoids and sphenoids on both sides The cells had a sort of doughy consistency due to thickening of the intracellular membrane, a condition which I have observed at operations in several other cases with very few clinical symptoms His eyes began to improve immediately after the operation He has since demonstrated beyond doubt the correlation of the nasal and ocular pathology, for every time he gets a cold his eyes will show a little redness for a day or two and subside as the cold clears up This reaction has grown very feeble and the last cold he had gave no eye reaction

Infection of the middle ear rarely causes secondary foci I can recall one case where I had done a radical mastoid in which a pus pocket remained in the upper part of the Eustachian tube This became partially locked in The patient had several choroidal haemorrhages which did not clear up till a secondary operation was performed on the ear and the pus pocket obliterated

THE INJECTION TREATMENT OF VARICOSE VEINS*

By ARTHUR M DICKINSON, M D, ALBANY, N Y

THE treatment of varicose veins by chemical obliteration appears to be a sound advance in therapy It is in reality not a new method for such procedures have been in use to a limited extent for at least fifty years Various solutions were used then, such as ferric chloride ferric sulphate combinations of iodine and tannic acid, compounds of mercury, phenol, etc Interest in this method of treatment probably began as a result of experiences in treating aneurisms with coagulants such as ferric chloride With the development of intravenous therapy, requiring injection of mercury compounds, bicarbonate solutions, saline, etc, various workers noted that the vessels used for the injection sometimes became obliterated, this stimulated investigation as a result of which the modern injection treatment of varicose veins came into being

The pathological anatomy of the condition

ment instituted about fifty hours from onset. The patient was given two liters of 0.45% NaCl solution into the vein and drained for eight hours. During this period the patient showed considerable clinical improvement. He came out of a deep coma but later lapsed into coma and died. Autopsy revealed a plastic exudate on one of the frontal lobes. There was no hydrosis of the brain or other organs in the gross or microscopic specimens.

Leighton reports three recoveries in ten cases. These cases were treated by continuous drainage and lamienectomy. Lamienectomy allows of better drainage since there is often difficulty in keeping the needle in the canal continuously for a long period of time. Kolmer reports two recoveries in eighteen cases of septic meningitis. He used intra carotid injections of sera and solutions with intermittent spinal drainage.

Syphilitic Meningitis: Syphilitic meningitis in infancy causes idiocy, hydrocephalus and various types of paralysis.

Baby S.—five months old—colored—entered the hospital July 19, 1930 with signs of acute meningitis. There was a rigidity of the neck and back and bulging fontanelle. The spinal fluid was under a pressure of 22 m.m. mercury, with a cell count of 90, 98% mononuclear cells. Globulin slightly increased. Spinal fluid and blood Wassermanns showed complete fixation.

The treatments given were as follows: Sulpharsphenamine intramuscularly 0.2 gms. every five days for ten doses, with daily inunctions of mercury. Following this bismuth salicylate was given once a week until September fourth.

At this time the spinal fluid gave a normal cytology. No meningeal symptoms were present, but the head was enlarging about twice its normal rate. There was a bulging fontanelle. Both blood and spinal fluid were still positive to the Wassermann reaction.

September 18th:—Forced spinal drainage for 24 hours using 1000 c.c. of 0.45% NaCl solution containing 0.2 gms. of neoarsphenamine. 271 c.c. of spinal fluid was obtained.

October 14th—Forced spinal drainage for 18 hours. 1000 c.c. of 0.45% NaCl solution containing 0.4 gms. of neoarsphenamine was given into the vein. 200 c.c. of spinal fluid was obtained.

November 11th—Forced spinal drainage for 25 hours. 300 c.c. of 0.45% NaCl solution was given into the vein with 0.2 gms. of neoarsphenamine. 184 c.c. of spinal fluid was obtained.

December 31st—Forced spinal drainage for 32 hours. 1000 c.c. of 0.45% NaCl solution containing 0.9 gms. of neoarsphenamine was given into the vein. In addition 225 c.c. of water was given by nasal drip. 245 c.c. of spinal fluid was obtained.

Since December 31st the spinal and blood Wassermanns have remained negative. The case is still under observation and there is no evidence of the activity of the disease. Since the first drainage the head has grown at a normal rate.

It is possible that when arsenicals are introduced into the blood stream with a hypotonic solution, a larger percentage of the arsenic might be drained through the lesions of the central nervous system.

Summary: It is evident that much more clinical and experimental data will need to accumulate before we can draw any conclusions as to the efficacy of forced spinal drainage in the treatment of infections of the central nervous system.

The treatment is theoretically sound.

The case of poliomyelitis seemed like an acutely fulminating case. We can not conclude that the treatment was responsible for her recovery for many cases of poliomyelitis recover without any treatment.

Forced spinal drainage should not be confused with continuous spinal drainage. Continuous

spinal drainage is of questionable value in the treatment of preparalytic poliomyelitis although it has been used successfully in certain cases of septic meningitis. The abrupt change in the cytology of the spinal fluid of the poliomyelitis case, coincident with the intravenous injection of the hypotonic solution presents further evidence that we were washing fluid through the lesions.

The improvement of the encephalitis case during the drainage was most impressive

My work with this method of treatment has convinced me that it is a safe procedure.

BACTERIOPHAGES AS A HELP IN THE TREATMENT OF INFECTIONS IN CHILDREN*

By WARD J. MacNEAL, M.D., NEW YORK, N. Y.

From the Department of Pathology and Bacteriology, New York Post Graduate Medical School and Hospital
These studies have been supported by a grant from the Josiah Macy, Jr., Foundation.

SINCE the pioneer observation of transmissible autolysis of bacteria by Twort[1] in 1915 and the subsequent extension of such observations, especially by d'Herelle,[2] there has been produced an extensive literature dealing with the general subject of the bacteriophage phenomenon and its possible importance in infectious diseases. The phenomenon itself is one of peculiar interest in general biology and its observation has introduced an uncertainty in regard to minute forms of life, which has been compared to the influence of the discovery of radium upon the elementary ideas concerning molecular and atomic structure. With these more theoretical conceptions of general biology we are not at present concerned.

D'Herelle's classical example of the phenomenon may be observed as follows: Take a small amount of stool from a patient convalescing from bacillary dysentery, suspend it in broth and filter through a porcelain filter to obtain a bacteria-free filtrate. Add a drop of this filtrate to a young broth culture of the dysentery bacillus and place the culture in the incubator. In a few hours it is diffusely clouded with bacterial growth, but soon thereafter, ordinarily in eight to twelve hours, the broth becomes perfectly clear and it may no longer be possible to demonstrate the bacteria in it either by microscope or culture. A drop of this clear liquid added to a new culture of the dysentery bacillus brings about a repetition of the phenomenon and this may be repeated indefinitely. Obviously the agent which causes this solution of the bacteria is being reproduced in increasing amounts. Its precise physical, chemical or possibly biological nature is not clearly understood. It is the bacteriophage for the dysentery bacillus.

Analogous filterable agents have been found which will cause dissolution of other bacteria, such as the typhoid bacillus, the colon bacillus, the bacillus of green pus, the golden staphylococcus. In fact there is reason to think that the phenomenon may be quite general for all the bacteria and that persistent search may be rewarded by the discovery of a bacteriophage for each pathogenic microbe or at any rate for many of them. The tubes and culture dishes here shown illustrate the phenomenon as it occurs in broth cultures and in agar plate cultures of the colon bacillus and the staphylococcus.

From such examples of complete destruction of the bacteria one may gain the impression that the bacteriophage always destroys the bacteria against which it is potent. Such, however, is not the case. Frequently one may observe the apparently complete clearing of the broth culture only to have it become cloudy again after twenty or more hours because of the growth of bacteria which, although tainted by the bacteriophage, are nevertheless sufficiently resistant to it so that they continue to survive and multiply in its presence. The bacteria of such secondary growth show peculiarities of individual shape and structure and in colony form as well as alterations in virulence, which have furnished themes for an extensive literature. Furthermore, one observes that various environmental conditions influence the outcome of the struggle for existence on the part of the bacterial cells in the presence of the bacteriophage. Significant contrasts are readily obtained by incubating identical mixtures at different temperatures. In our laboratory, experiments carried out by Miss Frisbee[3] have revealed a remarkable influence exercised by the hydrogen-ion concentration of urine in the bacteriophagy of the colon bacillus in urine. The significance of these results for the treatment of infections of the urinary tract is obvious. Somewhat analogous experiments by Miss Applebaum[4] have revealed an influence ex-

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 3, 1931.

ercised by the presence of blood, blood serum and purulent exudates, tending to impede the action of the bacteriophage. Laboratory experimentation of this sort shows that the bacteriophage phenomenon in the body of the patient may be very different from that seen in the test tube and indicates that the environmental conditions *at the site of the infectious process* must be made favorable to the bacteriophage and unfavorable to the bacteria, if the most desirable results are to be attained in the treatment.

Final decision as to the therapeutic value of bacteriophage must rest upon the results of clinical application; not upon the results in a few instances, for we all know that some patients get well in a most surprising fashion and evidently quite without regard to our treatment, while others succumb to their disease without apparent excuse and much to our chagrin and discomfiture. This is, perhaps, more often the case in children. The value of bacteriophage will not, in my opinion, be established by those enthusiasts who would exploit it as a panacea nor will the bacteriophage be finally discredited by those careless and inexpert workers who apply it without intelligent regard to its limitations and without skill in its application, much harm though they may do. The decision in regard to bacteriophage will come rather from the work of those patient students who are willing to make a careful study of the clinical application of this agent to disease under various conditions and by various technical methods and who are willing to subject to critical scrutiny their results, both favorable and unfavorable.

Our attempts in the therapeutic application of bacteriophage have been directed especially to infections with the colon bacillus and the staphylococcus.

In entero-colitis and dysenteries the use of bacteriophage, active against various enteric organisms, the dysentery and paradysentery bacilli and the colon bacillus, administered by mouth and by colonic irrigation, appears to exercise a favorable influence on the course of the disorder. From our limited experience we are convinced that it does no harm in these cases and we believe there is here a wide field of usefulness. Bacteriological examination of the stools should be carried out in conjunction with the treatment. D'Herelle is especially enthusiastic about the successful use of bacteriophage in the intestinal infections, particularly the dysenteries.

In infections of the urinary bladder and renal pelves with colon bacilli we have had, in collaboration with Dr. Joseph F. McCarthy, Dr. J. S. Ritter and Dr. H. D. Furniss, a somewhat extensive and varied experience. Pyelitis rarely leads to death. Spontaneous recovery is not unusual. In many instances the bacterial infection persists for years with only occasional periods of serious discomfort to the patient. The goal of bacteriophage therapy should be complete eradication of the bacteria from the urinary tract, not a mere symptomatic relief. Obviously an intimate bacteriological study of the urine must be carried out as a control of the treatment.

In one instance, Dr. Ritter, by a single instillation of specific bacteriophage through ureteral catheters into each renal pelvis of a girl of eight years, was able to eradicate completely the colon bacilli, so that subsequent urine specimens were bacteria free. In other patients, however, this method of applying the bacteriophage has given less fortunate results and those of us who have been concerned with the laboratory part of this study have come to believe that elaborate instrumentation of the urinary tract is undesirable during treatment with bacteriophage, not only because of the risk of infection with extraneous bacteria, but also because the slight injuries to the epithelial lining of the urinary passages appear to favor the continuance of the original bacterial infection even in the presence of a potent bacteriophage. Greater success has been attained by somewhat less dramatic procedure. Briefly, the patient is put to bed on a very regular light diet with abundant fluid intake. The urine, collected by aseptic technic, without catheter, each morning and evening, is at once tested to determine its hydrogen-ion concentration. The reaction of the urine is brought close to the neutral point by oral administration of a drug with residual alkali such as potassium citrate, 5 to 20 grains in watery solution, every four hours. Practically always the urine is naturally acid. If it is too alkaline, this can be corrected by oral administration of acid phosphate or ammonium chloride. Two or three days may be required to get the urine nearly neutral. The patient nearly always becomes comfortable under this regimen and there is no pressing need for hasty application of the bacteriophage, which is, meanwhile, being developed to a high potency against the patient's bacterial strain by serial filtrations in the laboratory. When the bacteriophage is finally ready and the urine is remaining nearly neutral, pH 6.6 to 7.2, one begins with subcutaneous injection of bacteriophage, 0.5 c.c., 1.0 c.c. and 2.0 c.c. on successive days. On the second and third of these days one introduces into the bladder, by rigidly aseptic and gentle technic, through a small soft catheter, about 10 c.c. of the bacteriophage preparation diluted with 100 c.c. of sterile saline solution and the patient is encouraged to retain this liquid as long as may be convenient. Subsequently the patient remains on the regular diet with abundant fluids and regulation of reaction of the urine as before. Bacteriological examination of the urine should be done 48 hours after the last instillation, for bacteria and for presence of bacteriophage; and again five days later. Ordinarily a few living bacteria still persist in the bladder urine. One now introduces into the bladder about 100 c.c. of sterile distilled water, to which has been added 10

c c of one per cent silver nitrate This is repeated after 24 hours Other silver preparations may be used if desired Two days after the second silver treatment the bacteriological examination of the urine is made; the patient is allowed to be up and the alkali therapy is changed over to acid phosphate coupled with administration of methenamine during a convalescent period of two to three weeks A final bacteriological examination should show sterile urine

More recently we have had occasion to employ the bacteriophage for the colon bacillus by intravenous injection, with successful outcome in one case of blood stream infection in conjunction with pelvic thrombo-phlebitis in a young woman The chills and febrile responses to intravenous bacteriophage therapy are so disturbing that we have so far, employed this method only in desperate cases and not in the infections restricted to the urinary tract It may, however, prove useful there also

In wounds, accidental or surgical, infected with colon bacilli alone or mixed with staphylococci, local application of wet dressings impregnated with bacteriophage potent against one or both these organisms have frequently exercised a remarkably favorable influence upon healing

Osteomyelitis, so frequently due to infection with *Staphylococcus aureus* has been treated with the aid of bacteriophage in two ways In the patient with suppurating bone lesions, the surgical removal of sequestra and sauceration of the lesions has been followed by the introduction of the bacteriophage for staphylococcus vaseline dressing and immobilization by plaster This method, which has been described by Patterson and Albee,[5] has been followed by favorable clinical progress in a number of patients Doctor Albee has expressed with enthusiasm his conviction that the bacteriophage is a distinct aid in chronic osteomyelitis In the earliest stage of the disorder, when the blood stream yields positive cultures of the staphylococcus and the localization of the skeletal lesions still remains indefinite, the intravenous injection of the bacteriophage appears to halt the progress of the lesions in the bones In a boy of 15 years with positive blood culture and severe localized pain in the extremities, treated in this way, the osteomyelitis failed to reach a surgical stage although the patient succumbed to a pericarditis after a month

Furuncles and carbuncles of the skin and subcutaneous tissue offer a field for bacteriophage therapy in which the methods of application are already fairly well standardized and the results good beyond question Cipollaro and Sheplar[6] are presenting results in this field at the meeting of the American Medical Association at Philadelphia, June 11, 1931 A baby, male, aged 10 months, on the service of Dr De Sanctis, treated in collaboration by Dr J M Sloan, has not been included in the series of Cipollaro and Sheplar This baby was severely ill with large carbuncles, involving practically the entire area of both buttocks and presenting multiple pin-point apertures in the skin, on May 5, 1931 The general condition was so poor that we began with very minute dosage, 1 c c of a 1 10 dilution of staphylococcus bacteriophage prepared in a protein-free asparagin medium This was injected through a fine needle into the subcutaneous tissue near the most prominent areas on the right buttock Culture taken at this time yielded *Staphylococcus aureus* which proved to be quite susceptible to the bacteriophage preparation *in vitro* Immediate improvement in the general condition and behavior was noted by the nurse Locally, however, the buttock appeared more indurated the next day Local injections of increasing amounts of bacteriophage up to a final dose of 2 c c of the undiluted asparagin preparation were given on May 6, 7 8, 9, 11 and 12 Cultures from two openings on May 12 yielded a slight growth of *Staphylococcus aureus* from one, and only an air-contaminating large rod from the other On May 14 the lesions on the buttocks were practically healed but on May 16 a sole remaining small furuncle was drained through a small opening Meanwhile a small furuncle which appeared on left little finger on May 6 1931, was injected with a minute drop of bacteriophage and it healed promptly and on May 7 another which had just appeared on plantar surface of right middle toe was effectively treated in a similar way The photograph of the baby's back (Figure 1) taken on May 22 gives

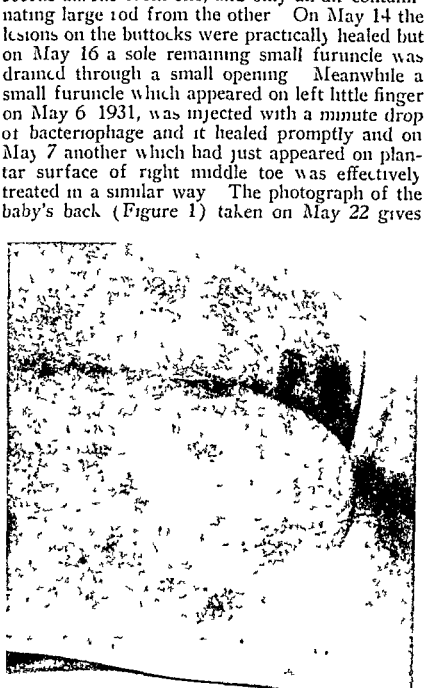

FIGURE 1

Photograph taken on May 22, 1931, showing condition of buttocks after bacteriophage treatment May 5 to May 12

some idea of the area originally involved and the absence of scars. Pigmented spots mark the sites of the minute spontaneous openings in the skin.

Infection of the blood stream with *Staphylococcus aureus* and the less common septicemia due to the colon bacillus present therapeutic problems which challenge our best efforts. When the septicemia has taken origin from an accessible superficial wound we have employed the bacteriophage in copious amounts introduced into the wound itself along with subcutaneous injections adjacent to the wound and at a distance. Two adult patients treated in this way have recovered from the blood stream infection and one of them is at work in apparent good health. The other remains, after a year, disabled by persistent osteomyelitis of a thoracic vertebra, which appears to represent a residual metastatic localization of the staphylococcus which was in the blood stream. In another patient, previously mentioned, a young woman with pelvic thrombophlebitis and colon bacillus septicemia following abortion, the bacteriophage for colon bacillus was injected intravenously. The reactions were severe but the blood stream became sterile and the pelvic condition slowly subsided with complete recovery of the patient.

In septicemias of children our experience has been somewhat less fortunate. A girl of 20 months with multiple abscesses of the scalp, temperature 104 and rasping precordial murmur, was found to have a blood stream infection with *Staphylococcus aureus*. The bacteriophage was applied to the open lesions on the scalp and by subcutaneous injection. For a time there was encouraging clinical improvement, but a fatal termination resulted after two weeks. The pericardial sac was greatly distended with thick pus, in which the *Staphylococcus* was still found by culture. A school boy of 15 years, previously mentioned, was admitted on January 28, 1931, with temperature 104.6°, pain in right hip, left ankle and in arms, petechial hemorrhages in the skin, and friction sound over the heart. The blood culture yielded abundant *Staphylococcus aureus*. Intravenous treatment with bacteriophage asparagin preparation was begun on January 31 and continued to February 19, 1931. The total amount of undiluted asparagin bacteriophage injected intravenously during this time was 987 c.c. For a time there seemed to be clinical improvement. The blood culture taken on February 2 developed very slowly and was positive only after 48 hours. Subsequent blood cultures were negative. The pains in the extremities improved and *x*-ray examination disclosed no evidence of bone lesions. On the other hand the pericardial sac became more and more distended. Pericardial tap on February 19 yielded a thin sero-purulent fluid in which staphylococci were found by culture. The patient died on February 24. In both these patients the pericardial localization was evidently present before the bacteriophage therapy was initiated. Our experience in septic pericarditis, therefore, has been entirely without success so far. In the future we have in mind to try an early introduction of bacteriophage into the pericardial sac in conjunction with early tap for drainage.

What has been here presented represents a report of work in progress and not a finished investigation. Your Chairman, Dr. Pease, thought that it might interest you. He has had opportunity to see some of the work. We are continuing and hope, with greater experience, to be able to utilize the bacteriophage phenomenon in an increasingly effective way.

THE PLACE OF THE OTORHINOLARYNGOLOGIST IN THE TREATMENT OF EYE DISEASES*

By E. ROSS FAULKNER, M.D., NEW YORK, N. Y.

THE relation of certain eye conditions to focal infections in the nose and throat has been the object of considerable study and discussion in recent years. The observation that such a correlation exists goes back many years, but in the beginning there was only an occasional report with rather vague suspicion as to the exact correlation. Before the days of the Wasserman

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 2, 1931.

test, no doubt many cases were diagnosed as syphilis which were really due to a focal infection; and here I wish to note how closely the lesions of a focal infection can imitate syphilis, not only in vascular degenerations of the eye but also in other parts of the body. The typical gumma is never found to be due to a pus focus but many degenerative changes undoubtedly can be ascribed to a residual focus of infection from the pus organisms, such effects being often secondary to absorption of toxins from nasal or throat infection. The proximity of the eye to the intranasal sinuses renders certain inflammatory processes closely correlated and both structures may be involved at the same time. Thus an ethmoiditis may be associated with an orbital abscess or cellulitis and the pathology may be more evident in the orbital complication. This is one type of case which has passed from the realm of ophthalmology to that of rhinology in the treatment, though in the management of the case cooperation between the two specialties is most desirable. They were formerly treated almost entirely by the oculist and treatment was an immediate operation. The original cause, which is practically always a sinusitis, was left alone. Though I know of no statistics on the subject I am told that the results were very bad, with a high mortality from meningitis. Later on with the recognition of the fact that the condition was due to involvement of the ethmoid and frontal cells with a rupture into the orbit the cases were treated by the sinus surgeon. They also made the mistake of being overzealous on the operative side and usually resorted to an immediate operation, doing a more or less radical sinus operation in the acute stage. They also achieved an abnormally high mortality. I regret to say that many rhinologists still regard these orbital blowouts as an occasion demanding immediate surgical procedure. During the past twelve years I have seen many of these cases, probably an average of four or five a year, and I have come to treat them much more conservatively. My experience would compel the conviction that one can wait several days on practically all of them and that not more than twenty-five per cent of them will need to be operated on at all. Treatment by shrinking up the nose several times a day and applying suction will always be worth a trial and in the majority of cases will succeed. If it does not succeed, the operation will be much safer when the process becomes more localized and the virulence of the infection has decreaseed. I reserve operation for those cases where no drainage can be established through the nose, where pain and temperature are increasing with more marked exophthalmos and fixation, or where vision is failing steadily from pressure on the optic nerve. When surgery is attempted a certain minimum should be done. This will mean an external incision with exenteration of the ethmoids to provide free drainage into the nose. A drainage tube inserted into the frontal through an opening in the floor and brought out externally will provide safe drainage of the frontal sinus. A subsequent operation should be done to clean out the frontal and close the external wound. Cases which were not operated on have shown no tendency to recurrence and *x*-rays taken afterwards have showen scarcely any trace of the original infection.

A simple mucocele may cause pressure on the eyeball, producing external displacement and proptosis. This should be dealt with by an external operation and will usually necessitate an exenteration of the entire ethmoid labrinth.

We will now consider the various intrinsic diseases of the eye which may be associated with focal infections in the nose and throat. Perhaps, nearly all oculists belive that infection of the tonsils or teeth may act as focal infections and cause such conditions in the eye as optic neuritis, retinitis, choroiditis, iridocyclitis, episcleritis, and keratitis, but when the subject of sinuses arises, we will find considerable variation of opinion. You may occasionally find an oculist of repute who will deny that sinusitis ever causes any of the inflammatory diseases in the eye itself, or some rhinologist who will hold the same view and even pronounce a negative finding on examination of sinuses where there is ample evidence that distinct pathology is present. The discrepancy in opinion seems to arise from the fact that many of the sinus infections which produce eye complications are of rather a low-grade, hyperplastic type without pronounced symptoms. The easily recognized form of sinusitis wth a purulent discharge is not usually associated with eye lesions. That this type may occasionally cause such complications, however, does occur, though I think all observers regard it as the exception rather than the rule. The diagnosis of sinusitis of the milder type presents considerable difficulty and when the oculist has excluded every possible known cause and "passes the buck" to the rhinologist to make a positive statement in regard to the condition of the sinuses, the latter often finds himself in somewhat of a dilemma. His first function should be to make sure that other causes have been eliminated. If there are any bad teeth, these should be extracted. Tonsils showing any suspicion should be removed. If there is an obvious sinusitis and a bad history of repeated head infection, treatment should be initiated at once. In the obscure cases repeated examinations with the pharyngoscope should be made and the best possible sinus *x*-ray obtained as soon as possible. A positive *x*-ray will be good evidence but should be supplemented by clinical findings. A negative *x*-ray may not be the final answer, as one may occasionally find some pathology by repeated examination which the *x*-ray has failed to detect. Bad anatomy in the nose,

such as a large spur on the septum with enlarged middle turbinates, producing bad ventilation of the ethmoid region, will be a predisposing factor, always worth noting. A slight thickening of the membrane over the posterior ethmoid and sphenoid region with a shiny, oedematous appearance is often present, or the membrane may appear much redder than normal. The nasopharynx will often show a granular tract on one or both sides extending under the posterior pillar. This will indicate a chronic discharge from the sinuses and although scarcely noticed by the patient will often be the most positive evidence of sinus infection that one is able to obtain. Once a tentative diagnosis has been made, treatment will usually be surgical. If the eye lesion is not severe and if the oculist thinks there is no danger in a delay of a week or two, intranasal treatment may be tried and the eye carefully watched. In retrobulbar neuritis it is not usually advisable to wait very long, but in young subjects whose regenerative powers are very strong a good result may be obtained even though the process has been going on for some time. In older patients it is important to remove the cause as quickly as possible and one should not wait very long before resorting to surgery. In the series of 44 cases reported by the late Dr. E. S. Thomson[1], in which the various eye affections were associated with infected sinuses and tonsils, operative procedure was carried out almost as soon as the diagnosis was made and the earlier the operation the better the results. Dr. Thomson had a large experience in this field and his conclusions were that sinus disease caused iritis, cyclitis, retinitis, and choroiditis in almost as great frequency as it caused optic neuritis. He also stated that the diagnosis of the casual relationship is so difficult for the rhinologist in many cases that it must remain for the ophthalmologist to decide when the sinus operation should be done.

Infection of the lacrymal sac may be secondary to nasal infection and will not respond to treatment till the intranasal condition has been treated. Obstruction in the nasal duct can also occur from inflammation inside the nose extending into the duct. Occasionally one sees the opening of the duct in the inferior meatus occluded from a swollen or polypoid inferior turbinate. Removal or cauterization of a part of the turbinate may help this condition but the results are not always satisfactory. The West operation for removal of an old chronic, suppurating sac by the intranasal route is a well-devised procedure but is rather difficult technically and unless thoroughly done is not likely to provide much benefit to the patient.

When the tonsils are suspected as a source of infection the diagnosis can usually be made with quite a positive degree of certainty. Any tonsil containing thin, liquid pus which can be demonstrated on slight pressure or suction is an obvious focus and should be removed at once if eye symptoms are present. There is, however, a possibility of a tonsil being the cause of mischief where the infection is not so obvious. One may find it very difficult to demonstrate any pathology in a small, buried tonsil stump and yet it may be the real source of the infection. I have advised the removal of such tonsils on speculation on several occasions and found much more than I had suspected. A history of an attack of tonsilitis at any time during the patient's lifetime may be all the evidence obtainable in some cases.

The late Dr. Leon White[2] who did a great deal of work in the relation of sinusitis to eye infections came to the conclusion that tonsils and teeth were more often the original cause of such infections than the sinuses. My experience has been more with the cases with sinus pathology but the cases from other causes may have been sent to other specialists so I cannot draw conclusions in regard to their relative frequency.

I now wish to report briefly three cases which will best illustrate the observations of this paper:

The first was a case of bilateral retrobulbar neuritis. A girl aged 13 years, brought to me the 15th of June, 1926, had started to lose vision in April in the left eye, and three weeks previous to the time I saw her the right eye began to fail. Her father was a doctor and an extensive investigation had been made in a large city. Finally, a diagnosis of suspected brain tumor had been made. They were then on their way to Boston to consult Dr. Cushing. His visit to me was to get my recommendation for a New York oculist. On inquiring about the case, I found out she had had a bad attack of influenza a month before the onset of the eye trouble. I asked him to bring the child to my office and let me see her. I found she had some mucoid discharge in the back of her throat and some congestion in the posterior ethmoid and sphenoid region with a thickened septum. I referred her to Dr. E. S. Thomson and he reported by telephone at once that she had a double optic neuritis with 20/200 in the left eye and 20/40 in the right, and said it looked very much like a sinus condition. With this evidence and my own findings I decided to open the ethmoids and sphenoids on both sides. This I did on June 16th, doing a submucous, complete exenteration of ethmoids on both sides and opening both sphenoids. In forty-eight hours the sight in the right eye was normal and three days later the sight in the left eye, the bad eye, was normal. She has remained perfectly well ever since. This case illustrates the remarkable regenerative power of the nerve in a young patient. It also illustrates the lack of recognition on the part of the profession of these important pathological relations as this patient's sinus condition had not been suspected.

The second case was a man of 48 who had lost the sight of his left eye from an accident in boyhood. Over a year previous to the time I saw him

his vision in the right eye had begun to fail He had gone through an elaborate investigation during that time having spent several months at the Mayo Clinic and having seen many of the best specialists in the country His eye lesion was a choroiditis with recurring haemorrhages in the macular region, the vision failing somewhat after each attack He gave a history of an infection in the right antrum fifteen years before This had been irrigated three times a week for six weeks and pronounced cured During the time of this antrum infection he had run a temperature and had sweats After the onset of his eye trouble he had had this antrum irrigated several times with no discharge found and no improvement in his eye condition The x ray at this time showed some cloudiness of the right antrum The clinical examination showed practically nothing Tonsils had been thoroughly removed and on irrigation of the antrum the return flow was perfectly clear In view of the rather desperate prospects and relying on the past history of such an antrum infection I advised a radical antrum operation The oculist who sent him to me thought my evidence rather flimsy and was very sceptical of my supposition that an antrum infected fifteen years before could have anything to do with the present condition I referred to the chronicity of syphilis and remarked that other infections under some conditions could last just as long After much persuasion I was allowed to open the antrum intranasally He showed no improvement after this, in fact I thought he was worse and was more or less septic for some time I felt certain that I had merely stirred up a focus and had not removed it He went away and continued slowly to lose his vision A year later he was sent back to me by Dr DeSchweinitz His vision was then 18/200 and this time I was able to persuade him to have a radical antrum done At the operation, I found a mass of granulation tissue on the floor half an inch thick but no free pus I cleaned this out and he made a steady recovery his vision coming back to 20/40 in two months

The third case was a young man of 26 who had suffered from frequent recurring attacks of iridocyclitis, the first attack occuring seven years previous to the time I saw him He had had his tonsils removed and this gave him a respite from the attacks for nearly three years When the attacks returned, his antra were operated on, a double Caldwell Luc being done on both sides, but he got no result and during the past year his condition had been gradually getting worse in spite of the fact that he had been sent to Arizona for three months His ethmoid sinuses had been examined by several specialists but were considered normal I examined him several times and always found slight œdema of the membrane with increased redness over the ethmoid area On the advice of Dr E S Thomson I opened the ethmoids and sphenoids on both sides The cells had a sort of doughy consistency due to thickening of the intracellular membrane, a condition which I have observed at operations in several other cases with very few clinical symptoms His eyes began to improve immediately after the operation He has since demonstrated beyond doubt the correlation of the nasal and ocular pathology for every time he gets a cold his eyes will show a little redness for a day or two and subside as the cold clears up This reaction has grown very feeble and the last cold he had gave no eye reaction

Infection of the middle ear rarely causes secondary foci I can recall one case where I had done a radical mastoid in which a pus pocket remained in the upper part of the Eustachian tube This became partially locked in The patient had several choroidal haemorrhages which did not clear up till a secondary operation was performed on the ear and the pus pocket obliterated

THE INJECTION TREATMENT OF VARICOSE VEINS*

By ARTHUR M DICKINSON, M D, ALBANY, N Y

THE treatment of varicose veins by chemical obliteration appears to be a sound advance in therapy It is in reality not a new method for such procedures have been in use to a limited extent for at least fifty years Various solutions were used then such as ferric chloride ferric sulphate combinations of iodine and tannic acid compounds of mercury, phenol, etc Interest in this method of treatment probably began as a result of experiences in treating aneurisms with coagulants such as ferric chloride With the development of intravenous therapy, requiring injection of mercury compounds, bicarbonate solutions saline etc various workers noted that the vessels used for the injection sometimes became obliterated, this stimulated investigation as a result of which the modern injection treatment of varicose veins came into being

The pathological anatomy of the condition

* Vice Presidential address read before the Albany County Medical Society Albany N Y June 2? 1931

of varicose veins is interesting and a brief study of it is profitable as an aid to diagnosis and treatment. The veins of the lower extremity consist of a superficial and deep group. The internal saphenous vein, which is part of the superficial group, commences on the inner side of the foot and passes upward along the inner side of the leg; at the knee it dips behind the internal condyle and continues up the inner aspect of the thigh to the saphenous opening in the fascia lata, to terminate in the femoral vein about one and one-half inches below the inguinal (Poupart's) ligament. In its course upwards this vein receives tributaries from the leg and thigh. The internal saphenous vein is the larger of the two superficial veins and so is more commonly the site of varicosities. The external saphenous vein runs upward from the foot on the lateral aspect of the leg to the popliteal space where it empties into the popliteal vein. The deep veins of the leg follow the arteries and require no further description. The superficial and deep veins of the leg are connected by the perforating or communicating veins, six to eight in number. All of the veins, superficial, deep and perforating, are provided with valves. Under normal conditions. venous blood flows upward through both superficial and deep veins and the communicating veins carry blood from the superficial to the deep group only. The deep veins are well supported by muscle and fascia so rarely become varicose; the superficial veins, on the other hand, have little support except the overlying skin and so become varicose more readily. The causes which may operate to produce varicosities are many: congenital weakness, general loss of tone, pelvic tumors, pregnancy, strenuous physical work, tight garters, etc. It must be remembered further, that while the veins of the leg have valves to check the effects of back pressure, the abdominal veins have no valves and so any increased venous pressure from within the abdomen must be borne by the valves of the internal saphenous vein; when these become incompetent, the column of blood from above has free access to the saphenous system. As the etiological factor operates, whatever it may be, it causes increasing back pressure in the veins below. These gradually dilate and become tortuous, forming some varicosities. Then the valves become incompetent and more blood is forced down into veins below. The process continues until finally the deep veins bring the blood up only to have it spill back, downward through the internal saphenous. The superficial veins become more dilated and tortuous; there is stagnation of the blood and the tissues become edematous. As a final result, rupture of one or more varicosities may occur, pigmentation of the skin takes place due to deposit of hemoglobin in the tissues, ulcers form and we have the typical picture of a severe case of varicose veins.

The modern surgical treatment of varicose veins has for its purpose the removal of the internal saphenous vein in part or in entirety. The most popular method is probably that of stripping the vein with a vein stripper; this is followed by dissection and excision of venous branches. The actual technic varied in different hands but did require multiple incisions along the course of the veins. In addition many operators ligated and cut the internal saphenous vein just distal to its junction with the femoral vein in order to prevent back pressure from the abdominal veins.

The efficiency of any new method of treatment must be judged by comparison with former methods. Comparison of results in the treatment of varicose veins by surgical removal and by injection must take into consideration, the mortality rate, morbidity, end results and the all-important economic factor. McPheeters has recently published statistics of a comparative nature. In a series of 6771 operated cases, death resulted from embolism in .53 percent of cases, and post-operative deaths from other causes occurred in .41 percent, making a total mortality rate of .94 percent. On the other hand, in a series of 53,000 cases treated by injection, the mortality rate was .00754 percent or just about one-seventieth as great. The case operated upon remained in hospital an average of 15 days and did no work for 35 days. Patients treated by injection have no hospital confinement and may continue with their work during treatment. The danger of post-operative infection of the wounds after surgical removal of veins is real as contrasted with the minor danger of infection or slough after injection. Following operation, recurrences are noted in five percent at the end of one year and in 19 percent at the end of five years. Recurrences after injection treatment are placed at 10 percent in one year. However, recurrence after injection treatment only requires more treatment. Recurrences after operative treatment required further surgery or perhaps went untreated. Careful comparison of these two methods of treatment of varicose veins appears to indicate the superiority of the injection method.

Two tests which are of value in examining the patient with varicose veins are the Trendelenburg test and the Perthes. The Trendelenburg test is based on the rapid filling of a varicose vein by back pressure. The patient's leg is elevated and the blood allowed to drain out of the superficial veins; a tourniquet is applied high around the thigh. The patient then

stands up, if the superficial veins fill rapidly from below upwards, it indicates incompetency of the communicating veins, if they fill rapidly only after removal of the tourniquet, it indicates incompetency of the valves of the long saphenous vein The Perthes test can be used to demonstrate the competency of the communicating veins The patient stands and the superficial veins are allowed to fill Then a tourniquet is applied to the thigh and the patient takes some leg exercises If the varicose veins become smaller, the competency of the communicating and deep veins is established Competency of the deep veins must be established before any form of treatment of the superficial group is begun for if one return channel is blocked it would be unwise to attempt blocking of the only other return route Competency of the communicating veins is merely an index of the extent of damage already done by the back pressure

Contraindications to the injection treatment of varicose veins are few Before commencing such treatment, a general physical examination should be made with the idea especially in mind of eliminating possible general causes for the symptoms which appear to be due to varicose veins If there is obstruction to the deep veins as demonstrated by tests or as manifested by constant swelling of the extremity, we should not recommend treatment A history of prolonged post operative swelling of the extremity or of phlegmasia alba dolens should also put one on his guard Acute infection of the veins (phlebitis) either present or recent, is a positive contraindication Patients with Buergers disease or Raynauds disease are also to be avoided

The pathological results of the injection of sclerosing solutions into veins are interesting Within a short time after injection, there is formed within the vein, a thrombus of varying length and quite firmly attached to the vessel wall The vein is appreciably decreased in size and contains no free blood There is considerable perivascular reaction Later the entire mass becomes contracted into a cord-like scar without any lumen

Various solutions have been used in the injection treatment of varicose veins Of these the more popular are sodium chloride, sodium salicylate, dextrose, quinine and urea and combinations of some of the above We have been using sodium salicylate in 30, 40 and 50 per cent solution and prefer it to the others

A few points about the actual technic of treatment require explanation The needles used for injection are of rustless steel, 20 gauge, ¼ of an inch in length and with a short bevel This seems to be the most satisfactory type of needle although other types may be used The short bevel aids materially in decreasing the hazard of penetrating the farther wall of the vein Any good 5 or 10 cc syringe will do although one with an off set tip is much easier to use An easily adjustable tourniquet is a very essential part of the equipment Now as to the actual technic The patient stands and a tourniquet is applied to the area above the veins to be injected, then the patient lies down The veins to be injected are painted with tincture of iodine and then the stain removed with alcohol The needle is then inserted into the vein and the blood aspirated and discarded This procedure is facilitated by a two way valve, although it may be accomplished by removing and emptying the syringe The injection is then commenced If the patient has immediate pain, it is an indication that the solution is being injected outside of the vein In such event a local slough will develop unless the area is quickly injected with some normal saline to dilute the sclerosing solution If the needle is in the vein correctly there will be no pain until toward the end of the injection when the patient will complain of cramps in the extremity lasting about 30 seconds Following withdrawal of the needle firm pressure is maintained on the vein for two or three minutes to keep the vein walls collapsed, this intensifies the sclerosing action of the solution injected Then the tourniquet is removed In about ten minutes the patient is allowed to get up and go on Usually we apply a firm dressing to the injected area which is worn for 24 hours Two or three separate varicosities may be injected at one treatment In using sodium salicylate solution, there is a limit to the amount that can be injected with safety at one sitting We rarely use more than 5 cc of a 40 percent solution at one time In injecting small thin walled veins, the 30 percent solution is used, for thick walled veins the stronger solutions are used Treatments may be given at 4 to 7 day intervals, usually it takes 4 to 6 treatments to each leg to produce a cure The first treatments are usually given in the region of the knee, later treatments are given below and above this In cases of very severe varicosities where there is absolute incompetency of the valves of the long saphenous, ligation of the saphenous vein at its junction with the femoral vein is to be done

PSYCHOPATHOLOGY AND PSYCHOTHERAPY IN THE NEUROSES AND PSYCHOSES*

By A. A. BRILL, M.D., New York, N. Y.

ALL sorts of ideas crowd themselves into one's mind when one thinks of psychopathology and psychotherapy. The ideas naturally revolve around one's self, for in one's own mind, in one's sanctum sanctorum, everything is ego-centric. The thoughts which thus present themselves must perforce be somewhat censored, or better, sorted, for they are to be presented to the general practitioner in whom this subject is not as affectively endowed as it is in those who are, so to speak, forever steeped in it. I have lived in an atmosphere of psychopathology and psychotherapy for exactly twenty-eight years, and I find myself, as it were, at home therein, while the general practitioner has always considered these subjects more or less alien to himself and has looked upon them with an awry eye. His training precludes the acceptance of structures that he cannot see, at least with the microscope, and although the times are changing in this respect, the general practitioner still experiences an uncanny, nay comical feeling when he is confronted with psychopathological material. Some time ago, a very prominent pediatrician referred to me an idiot child with a note, which read: "I am referring this case to you for a psychoanalysis"! From the emotional display of the parents I could see that all their former despair of being the progenitors of a defective child was dissipated with the hopeful note from this learned physician. They felt sure that a psychoanalyst would give this child a new brain. This is the tragic part of my story; now comes the comical part of it, at least for the prominent occulist in question. This well-known professor of ophthalmology referred to me a middle-aged man with the note that the patient was suffering from hysterical blindness and that he was sure that I would cure him. Somehow, the patient did not impress me as one suffering from a psychic disturbance, but coming as he did from a great authority, I immediately dismissed my mental reservations. However, after taking the patient's history and examining him neurologically, I found that he was suffering from tabes dorsalis. "Is it possible that Dr. X. made such a gross diagnostic error," I asked myself, "Has he examined this patient's eye grounds?" I darkened the room and applied the ophthalmoscope and found that the patient had a bilateral optic atrophy.

I felt quite sensitive when I began to speak to this ophthalmologist over the 'phone; but to my surprise when I finally told him my findings, he burst out laughing, I could not quite see the joke. He said that he knew all about the atrophy, but hated to tell it to the patient. He did not wish to tell it even to me because he feared that my psychotherapeutic approach would thereby become impaired. He thought that if I knew that the patient was hopelessly blind, my treatment would lack the proper spirit and the patient would not be benefited by me. His logic was truly bewildering. It recalled the man who borrowed a kettle and when reproached for returning it damaged said: "In the first place I never borrowed any kettle, secondly it had a hole when I got it, and thirdly it was in perfect condition when I returned it." Thus far, I could not repay my ophthalmologist in his own coin, for even if I could find a patient with a glass eye, whom I could send to the Professor to be treated, let us say for glaucoma, the patient would have to know about it.

I could add many more experiences of this kind to show that the average physician still looks upon psychotherapy with the same scepticism and irreverence that Benjamin Franklin entertained for mesmerism over one hundred and fifty years ago. Franklin, as you know, was a member of the committee appointed by the Academy of Science of Paris to investigate the reputed cures of Mesmer. After a thorough investigation the committee reported that the cures were genuine, but that the effect was due to the imagination of the patient, and that the subject was not worthy of further scientific investigation. However your attitude must be different; otherwise you would not have asked three psychopathologists, all votaries of psychotherapy, to come here and tell you about it. As I happen to have played some part in the development of psychopathology and psychotherapy in this country, I cannot do better than follow my own experience with these subjects from the time I became an interne in the Central Islip State Hospital in 1903 until the present. For, it is my opinion that prior to this date very little interest was displayed by the average physician in either of these subjects. You will, I hope, therefore, forgive me if I inject myself or rather my own experiences into this talk.

But, let us formulate or rather define the subjects under discussion. Psychopathology, which I would prefer to call here psychiatry in the broad sense, is that science which treats of the study and treatment of abnormal mental conditions, while psychotherapy is that mode of therapeutic procedure which treats neuroses and psychoses by psychic means. Psychopathology is thus a branch of clinical medicine, while psychotherapy is a healing method. (Cf. Hans W. Maier: Psychiatrie und Psychotherapie, *Schweizerischen Mediz. Wochenschrift,* 58, Jahrgang, 1928.)

Nowadays, there is no difficulty in obtaining

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 2, 1931.

physicians for state hospital service Most of the colleges and medical schools are now teaching medical psychology and psychiatry and the subjects are presented in a vivid and interesting manner, so that the students become interested in the subjects and attracted to them even before they reach hospital age For some reasons I have always been interested in the study of the mind, but my experiences with psychology and psychiatry while I was an undergraduate and a medical student were not conducive to draw me to the study of psychopathology In order to understand the normal or abnormal workings of the mind one must come in contact with human beings, but up to within recent years the academic psychologists were sort of clock makers, they spent most of their time measuring the sense perceptions, they taught us nothing that could be applied to the actual workings of the mind Nor did the medical schools teach us much psychiatry I believe I heard only a few lectures on psychiatry during my senior year Were it not for the fact that my professor of psychiatry accidentally discovered me and urged me to enter this field I probably would have gone into another specialty Thus, my interest in psychiatry started with suggestion, which is a human relationship, the professor was nice and friendly, so for his sake I overcame all objections to the disreputable name of the insane asylum, and all that went with it

It was my fortune to come into the state service when the New York State Hospitals entered a new epoch in psychiatric development It was shortly after Dr Adolph Meyer became the director of what is now the Psychiatric Institute and through his indomitable perseverance he converted the old insane asylums into psychiatric hospitals There I have learned much psychopathology, I mean gross and microscopic psychopathology, and when I reflect retrospectively on all that has happened since then in psychiatry, and attempt to condense it for you in a few sentences, I can say that many of the so called new discoveries now belong to what Hans W Mayer would call "brain mythology" We know for example that dentistry and surgery cannot cure insanities, but that we are justified in studying the relations of the vegetative nervous system to the inner secretions, especially to our affectivity, and we can hope that bio chemistry will explain some of the enigmas of the psychoses There is only one thing that I have learned in these years and this is *Some psychopathological disturbances may be explained in the future by somatic influences though at present we know very little about them, but I am absolutely sure that the psyche participates in all organic disturbances and that most of the psychopathic ailments can be diagnosed, explained, and cured only by psychic modes of procedure*

Perhaps it will interest you to know how I came to this cognition I am presumptuous enough to tell you that I made good use of the material at my disposal in the hospital But, after a few years the monotony of descriptive psychiatry began to pall on me I became tired first of my neuro pathological work, it was so deadly, and after a few years of clinical work, that, too, lost its attraction The patient was diagnosed, classified and his future psychic health depended on himself If he was a manic-depressive he would recover from the attack, if he was a schizophrenic he might improve only to a certain degree Everything was so hopeless and uninteresting It was then that I began to read about hypnotism and other psychotherapeutic methods Hypnotism was the form of psychotherapy then in vogue so I devoted most of my reading to this subject I was fascinated when I read Forel, Loewenfeld, Charcot and others I was interested when I read that psychotherapy is as old as mankind, that it was employed by primitive races as well as in the medicine of antiquity I read abstracts of Mesmer's *"De Planetarium Influxu,"* and followed mesmerism to hypnotism, and suggestion My heroes were Mesmer, Braid, Liebault, Richet Bernheim Charcot, Pierce, and our own Morton Prince and Boris Sidis, names of great psychopathologists and psychotherapists I began to practise hypnotism and suggestion and obtained results good enough to encourage me to go on I had no hope of curing the psychotics, but there were plenty of so called borderline cases whom I hoped to treat in clinics and in private practice (That we can now expect results even in the psychoses which are popularly thought hopeless, has been amply demonstrated by me and others Cf Brill The Application of Psychoanalysis to Psychiatry *Journal of Nervous and Mental Diseases*, Vol 68, No 6, Dec 1928, and Schizophrenia and Psychotherapy, *American Journal of Psychiatry*,—Vol IX, No 3, November, 1929)

In 1906, Drs Jelliffe and White published an English edition of "The Psychic Treatment of Mental Disorders" by the Swiss psychotherapist Dubois The book never appealed to me very much because I did not get any results from this form of therapy In justice to Dr Dubois, whom I later met and liked, I will say that my failures were due to my poor material All my patients were mental cases from the hospital, most of them in a state of convalescence I tried Dubois' method on a case of insomnia The patient in question, a young woman who was recovering from a hypomanic condition, was glad to listen to me, but the more I educated her and persuaded her, the more wakeful she remained I then succeeded in hypnotizing her,—it was not so simple as you may think—after a few treatments, she could sleep normally This and other

experiences decided me in favor of hypnotism as a psychotherapeutic procedure.

But, my experiences with hypnotism were the same as those of other psychotherapists. I could hypnotize some and failed with others, and being very narcistic, I felt terrible, nay cheap, when after I went through all the ceremonials, and finally said to the patient "Now, you are asleep," the patient would exclaim "No, I'm not!" In the spring of 1907, I decided to go to Paris in order to perfect myself in these psychotherapeutic methods. I visited the different centres, and finally entered the Hospice de Bicêtre in Pierre Marie's service. I expected perhaps too much when I went to Paris. I found that in comparison to psychiatry in New York, Paris was much behind. I found that the patients were still described according to Pinel's classification. And, as to the treatment of the psychoneuroses, which originally drew me to Paris, I was sadly disappointed. It was then that the same man who originally influenced me to go to the state hospital, advised me to go to Zurich to the Clinic of Psychiatry at Burgholzli, which was then directed by Professor Eugen Bleuler. Dr. Frederick Peterson was at that time a great admirer of Freud and in telling me to go to Bleuler and Jung he assured me that I would find the work there very stimulating; he, himself, had been there for a few months, and spoke very admiringly of the men and their work. He casually mentioned the fact that in Burgholzli they were applying Freud's theories to the cases. Dr. Peterson was right. Bleuler and Jung vivified my interest in psychopathology. There I found an enthusiasm for psychiatry, which I never saw before nor since I left Zurich. The interest, I might say zeal, was all due to Bleuler's infusion of psychoanalysis into psychiatry. (Bleuler: Textbook of Psychiatry, translated by A. A. Brill, The Macmillan Co., New York, 1924.) Under his instigation, all his assistants labored assiduously to prove, or disprove, experimentally Professor Freud's theories. We worked with the association experiments with the galvanometer, with the so-called normal test person, and with the patients. There I learned for the first time of Freud's work, whose therapy cures at the same time that it investigates, and unlike hypnosis and suggestion, which may remove symptoms, but never really cure, Freud's psychoanalysis not only removes the symptoms, but transforms the personality of the patient in such a manner that recurrences do not as a rule recur. In the Zurich Clinic we were all ardent Freudians. Bleuler revolutionized psychiatry because he changed it from a purely descriptive chronicle to an interesting human document. Instead of a dry description of the patient's normal and abnormal faculties, we now wished to know the whys and wherefores of his illness. It was not enough to say that the patient had delusions and hallucinations of this or that sort, hence he was a schizophrenic or an epileptic. Never mind the diagnosis. Professor Freud taught us that in order to enable us to do something for the patient, which is after all what we are striving for, we must endeavor to understand the dynamic forces which swayed him since his childhood, since his birth, for they are also at the basis of the neurosis or psychosis. Looking at psychopathology from this viewpoint, the yawning gap between the so-called normal and the abnormal vanishes. For the greatest confusion in the study of the neuroses and psychoses and the greatest injustices to a large class of sick people resulted from the theory of "mental degeneration" introduced by Morel and others of the French school. As Jones put it: "On the insecure basis of this hypothesis, Charcot introduced the term, 'Constitutional neurasthenia,' and Janet the allied concept of 'Psychasthenia.'" (Jones: The Treatment of the Neuroses. p. 18, Ballier, Tyndal & Cox, London, 1920.) When one reads Janet's cases in his "Psychasthenie," one finds there almost more psychoses than psychasthenics. But, psychasthenia means "mental weakness," which is as meaningless as Beard's term, neurasthenia, which means "nerve weakness," whatever this may mean.

All these confusions disappear when we follow Freud's approach to the study and treatment of the psychoneuroses. For beginning with hypnotism, which he learned from Charcot, and the cathartic method, which he got from Breuer, Freud combined the two and then developed his psychoanalysis. (Those interested may read the author's Psychoanalysis, Its Theories and Practical Application, 3rd edition, W. B. Saunders, Philadelphia, 1922.) He gave up hypnotism because not everybody can be hypnotized, and at best, you can only remove symptoms, but not the disease. Hypnosis imposes blind obedience on the patient, so that symptoms can be temporarily removed, but it gives us no insight into the play of forces that formed the neurosis. Moreover, there are some dangers in the use of hypnotism; to be sure they are not of the kind so often depicted in sensational literature and on the stage. One cannot be hypnotized for example into committing a crime as some judges and lawyers still seem to believe, but one can become, as it were, addicted to hypnotism. I know a man of about sixty whose headaches were first removed by hypnosis when he was eighteen, shortly before he emigrated from Vienna to Buenos Aires. Since then, this patient could go nowhere without first making sure that he would be near a hypnotist. When he was forced to visit New York City he wrote to Bellevue Hospital and ascertained that I was treating nervous diseases by hypnotism, and as soon as he reached New

York, he called on me and kept in almost daily contact with me until he left I have seen a few similar cases To illustrate the difference between the hypnotic and psychoanalytic therapies, Professor Freud gives Leonardo da Vinci's distinction between the two arts, painting and sculpturing "The art of painting," said Leonardo, 'works *per via di porre*, by placing small heaps of paint on an uncolored canvas while sculpturing is done *per via di levare* by taking away from the marble block as much as covers the surface of the statue therein contained" (Selected Papers on Hysteria, p 178 translated by A A Brill, Monograph Series Nervous and Mental Disease Pub Co) In other words, hypnotism concerns itself little with the emotional or psychic forces of the patient the psychotherapist imposes his own personality on the patient while psychoanalysis removes only those impediments which were wrongly superimposed on the patient's personality by his environment, and by exposing to the patient his own personality future psychic health is practically guaranteed For, the average individual brings along into the world all those attributes which are adequate enough for self preservation and left to himself if he would only survive, he would not have any neurosis or psychosis To be sure the present situation is quite different the world one encounters is no longer primitive, one must now adapt himself to a complicated civilization which is very difficult even for a normal child Moreover the child brings into the world an impulsive wild mental apparatus, which Professor Freud designates as the *Id*, the lawless, unorganized mind, the function of which is blind wishing In order to survive, the child must have nourishment and protection, fundamental needs lovingly gratified by the mother The wishes that emanate from the *Id* are therefore directed to the two primary instincts, hunger and love, which sway the whole animal kingdom In order to live one must satisfy both of these instincts Moreover, in order to adapt himself to our artificial civilization the child must be able to assimilate about 50 000 years of civilization during the first four years of his life His *Id*-mind meets with one rebuff after another, the outer world is hostile and cruel, it has no regard for the individual Nevertheless, the average child is adjustable and very soon, that part of his *Id* which meets the onslaught of the outer world through the various senses becomes endowed with consciousness and learns to differentiate between good and bad This educated part of the *Id* then constitutes the ego of the person and henceforth controls the rest of the id Later on, a part of the ego, develops into a still higher level, into what Freud calls the *Super ego*, which is the highest attainment of mental evolution in man Only those who attain this level have the capacity to absorb the highest assets of civilization The *Super ego* harbors all the ethical, moral, and religious principles, which were inculcated in the individual by his parents, especially the father, and later by religion, ethics, and law Once an individual attains the super-ego level he becomes endowed with a "conscience" which forever stands guard and watches the ego which in turn controls the *Id*, and insists upon "right for right's sake," and "virtue for virtue's sake" This gives you in a few sentences Freud's conception of the psychic apparatus, its earliest development and adaptation to civilization, but in order to correct some current misconceptions I will briefly explain a few more of Freud's principles

The first adjustment the child has to cope with is his home environment, of which the greatest force is the father If the latter is perchance absent, or if the mother is very indulgent or very aggressive, the child's environment is more or less influenced thereby, and in a sensitive person (constitution), it may result in a latter neurosis Let me add that these processes are not as simple as one might imagine

You have also heard so much about the fact that we Freudians lay so much stress on the sexual role in the origin of the neuroses and psychoses This is true only if you bear in mind our connotation of the term, sex Freud does not use the word, sex, in its narrow popular meaning, but conceives the sex impulse in the broad sense of libido which he defines as a quantitively changeable force which is directed to an object The child at first directs all his libido to his own ego, he loves himself only, to be sure he is at first in a very dependent relation to his mother, he leans on her for all his needs, but he does not consider her as someone apart from himself As the child grows older, he gradually withdraws the libido from his ego, and directs it to other objects, this is especially true after the age of puberty And, depending on the libido proportions he maintains on the ego and the object, his capacity to give and take libido, he is either normal or abnormal in his love life Some people can never detach enough libido from their own ego to love anybody else, their own ego absorbs it all, in which case the ego becomes so hypertrophied that the individual evinces delusions of grandeur All human relations are based on libidinous attachments regardless of conscious sensuous gratification

The oedipus situation, a Freudian shiboleth, refers to the various stages of adjustment between the parents and the child during the first four years of the child's life There is nothing mysterious or far fetched about this relationship Briefly, Freud maintains that the baby boy knowing that *everything good comes from his mother* wants her all for himself He is jealous of anyone who intrudes into his little world As the

father is his greatest rival, his innate aggressive hostility is naturally directed towards him. The child is still very selfish and sees no reason why he should tolerate any rival in his home. Every boy who has a normal father, that is, one who commands authority, will perforce dislike him. We were born to be free and independent and we do not like to be corrected and told what to do and what to eat, even if it is for our own good. Normally, however, the little boy gradually recognizes his father's status in the home and adjusts himself to him. This is especially the case when the child becomes independent and is able to give up the childish gratifications furnished by his mother, who is the source of contention. But, there is always a substitute for the father hatred, in the form of the teacher, the professor, the boss, etc. It seems that we must always hate or dislike someone. To be sure, if the father is of the right sort and understands the child, everything proceeds smoothly, and one can expect that the child will be normal.

It is impossible to go here into the deeper problems of our psychology. I shall, therefore, endeavor to illustrate what I said by the following case:

About seventeen years ago, a patient was sent to me from this very city by Drs. Stiles and Broad. He was a young medical student of about 24 years. For over four years he was treated for almost everything imaginable. He was introspective, hysterical, had headaches, and many other symptoms too numerous to mention here. He was treated first for auto-intoxication, then gastritis, then gastric ulcers. But, as Dr. Einhorn decided that he had no ulcers, his wisdom teeth were extracted and for good measure his appendix was removed. Then, he was sent to Battle Creek, where he remained for months, but his symptoms did not leave him. On the contrary, they became more diffused and more aggravated. For obvious reasons I am unable to go into the details of this interesting case. I brought it up to illustrate a few points mentioned. The neurosis was primarily due to the fact that the patient's parents lived a very unhappy marital existence. From the age of three, the patient saw his mother weep over the supposed wrongs perpetrated on her by his father. As he grew older, each parent played for his sympathy, with the result that he could not detach himself from either. He had to love and hate when he should have given up his infantile attachments, that is his mother love, and identified himself with his father. In other words, as a result of his parents' behavior, his psychosexual development was impeded and traumatized so that numerous weak spots or *fixations* resulted, to which he later regressed. From the age of puberty he found it hard to adjust his love life properly; he loved too hard or not enough and finally developed the neurosis. His libido stream was impeded in its outflow by the obstructions formed in childhood. His unconscious still struggled with his early parental images, in his unconscious he was still torn by the sympathetic interests for both parents. Such an unconscious struggle always ends in a neurosis. Dynamically expressed, according to Freud his neurosis was the result of a conflict between the ego and the id. The id impetuously demands gratification, but the ego by virtue of its contact with reality must curb and restrain the id-tendencies. You may not be able to follow me because I am not showing you how I proceeded with my therapy, but I can report to you that the patient has made an excellent recovery and has remained well ever since, which shows that we do not just remove symptoms.

If I could lead you into the actual dynamics of the symptoms, I could show you how each and every complaint was psychically determined by definite experiences in the patient's life, and that the nucleus of the neurosis was formed in early childhood. From what you have already heard about this case, you can readily understand the logic of Professor Freud's concept of the origin of neurotic symptoms. Please remember that sex does not necessarily refer to physical or sensuous outlets. The love relationship between parents and children is sexual in our broad sense of libido, though not in the popular sense. Many children, young and old, become neurotic in consequence of excessive parental love or because of a lack of it. Thus, a young girl of five became neurotic following her parents' separation when she was deprived of her father, and a younger girl merged into a typical catatonic type of behavior under the same circumstances when she was deprived of her mother. Both became sick because of a disturbance in their sex or love-life, which in civilized states plays a much greater part than the instinct of self-preservation.

Following the suggestion of some of the officers of this organization I was endeavoring to present the subject in as simple a form as possible. (Those who are interested are referred to Freud's original works, or to my "Psychoanalysis, Its Theories and Practical Application," 3rd edition, W. B. Saunders, Philadelphia, 1922.) The most salient point that I wish to impress upon you is the fact of *psychogenesis,* which has been accepted even by Freud's opponents. Briefly, it signifies that not only symptoms, but every trait of character, every peculiarity shown by a person, whether it is perceived as normal or abnormal—all of them originate from something definite in the person's experiences. You can comprehend why Professor Freud, starting with abnormal psychology—neuroses and psychoses—gradually developed also normal psychology, for it is the abnormal which teaches what is actually

normal One merges into the other—it is only a question of degree In his "Psychopathology of Everyday Life" (Translated by A A Brill, The Macmillan Co, New York, 1914) Professor Freud deals with those faulty actions, slips of all kinds, which one observes in the daily life of so called normal people He developed his theories of dreams in the same manner, by studying everything the patient presented to him, by ignoring the old prejudices that dreams are nonsense For in using his "continuous association" method, he soon realized that nothing is arbitrary or adventitious, that whatever the patient produces, any idea whatever in a dream, or in a joke, must have a good reason and definite meaning In solving the dream problems Freud gave the world the key to the solution of myths, folk-lore, fairy tales, and the history of civilization The child is father of the man was thus scientifically demonstrated, and what the biologists have shown in the somatic spheres, Freud has shown in the psychic spheres

It is for all these reasons that once I began to study psychopathology by means of Freud's Psychoanalysis the neuroses and psychoses assumed new meaning and new interest and no other form of psychotherapy could possibly appeal to me There is no objection, however, to any other form of psychotherapy as long as it helps You all practice psychotherapy when you show the patient that you are kindly disposed towards him and wish to help him for it is impossible to exclude the psychic element from any somatic ailments I have no doubt that a sympathetic interest will do as much, if not more, than a pill or a powder Indeed, Moebius has shown long ago that even such a specific as Quinine acted more effectively and more beneficially when administered by a sympathetic physician than by one who appeared indifferent to the malarial sufferer Hypnotism removes symptoms, persuasion and isolation may help, but all these methods touch only a small segment of the personality If we were to apply similar methods to physical diagnosis and therapy, it would mean that given a patient, with let us say, an inflammation and pain, all attention would be directed to these symptoms and no attempt would be made to discover the nature of these symptoms But, such narrow procedures belong to ancient times Nowadays, every physician worthy of the name wishes to diagnose the malady regardless of the symptoms Temporary alleviation does not cure In psychotherapy like in physical therapy the whole person must be considered, somatically a very small ulcer often spells lues, psychically a very insignificant idea or act, such as an eccentric behavior often connotes a compulsion neurosis or paranoia Psychoanalysis, as formulated by Professor Freud and his pupils, is the only form of psychotherapy that is all embracing It not only discovers the nature and origin of the malady, but at the same time also treats and cures the personality as a whole as shown by Dr Jelliffe, the pioneer in the application of psychoanalysis to organic conditions,—its effects on the soma are not less remarkable than those on the mental states

THE ORTHOPEDIC TREATMENT OF ANTERIOR POLIOMYELITIS *

By ARMITAGE WHITMAN, M D, NEW YORK, N Y

FROM the ideal standpoint the orthopedic treatment of poliomyelitis should begin the moment the diagnosis of the disease is made, and continue throughout the patient's lifetime Practically it begins when the acute symptoms have subsided and continues until the patient and surgeon are convinced that no further improvement is possible The aims of orthopedic treatment are three (1) The prevention of deformity (2) The maintenance of muscular tone (3) The maximum utilization of remaining muscular power by muscle transplantation and skeletal stabilization

So much confusion apparently exists not only in the lay but in the professional mind as to what may be expected from treatment, when it should be begun, and of what it should consist that I think we should do well to reflect upon the pathology of the disease

It is an inflammation centering in and about the anterior horn cells of the spinal cord, and either by haemorrhage into the cells or pressure about them depriving them of their function The muscles whose efferent nerve impulses are transmitted through those cells suffer flaccid paralysis Fortunately a majority of the cells lose their function from pressure rather than actual destruction Thus, as the inflammation subsides, power gradually returns to the secondarily affected muscles Supposing, however, that during that period deformity had been allowed to develop, no degree of returning nerve power could restore normal muscle function

Somewhat arbitrarily we have divided the dis-

* Read at a special meeting of the Medical Society of the County of New York held on September 18 1931 at the Academy of Medicine New York N Y

ease into three phases—(1) Acute, (2) Convalescent and (3) Chronic, and each phase has its different treatment.

The orthopedic treatment during the acute stage consists in the prevention of deformity, and, if I may use such a phase, the immobilization of the affected area. The idea of being able to immobilize a segment of the spinal cord may seem fantastic. If we place the affected limbs in plaster of Paris we have assured ourselves that at least as few impulses as possible pass through, and by their passage irritate, the inflamed area. The same principle was applied by Hugh Owen Thomas to the treatment of peritonitis, and I have no doubt that it was handed on by him to Sir Robert Jones. Unless I am much mistaken it is the only treatment that Sir Robert uses. It should undoubtedly be insisted upon until all muscular tenderness has disappeared. I think we all agree that muscular tenderness may be interpreted as a sign that the inflammation in the cord has not subsided. One of the strongest impressions left in my mind by the epidemic of 1916 was that the worst cases, and those in which the tenderness persisted longest, were those in which active treatment, usually I am glad to say, suggested by osteopaths or chiropractors, had been instituted too early.

When the acute stage has passed we encounter from the therapeutic standpoint the most perplexing phase of the disease. I think most orthopedic surgeons have agreed to set two years as the period of potential recovery, and feel that, except for correction of deformity, no operative treatment should be undertaken during that period. During that two year period the first essential is the prevention of deformity.

Deformity may occur (1) by the force of gravity. (2) By unopposed action of active muscles. (3) By habitual posture. (4) By functional use. The commonest example of the first is toe drop, caused by the attitude as the patient lies in bed, plus the weight of the bedclothes. Flexion deformity at the hip occurs by the unopposed action of the tensor fasciae femoris muscle, which, curiously enough, is almost never completely paralyzed. Habitual posture, as when a completely paralyzed person sits about, is in itself sufficient to cause flexion contractions at the hips and knees. Functional use as a cause of deformity may be seen when a patient with weakened back or abdominal muscles sits up unsupported, and develops curvature of the spine. All these factors must constantly be kept in mind, and deformities thus prevented rather than cured. I am confident that the profession at large has learned many of these lessons, for since the war I have seen nothing to compare with the horrible deformities that I saw throughout the state in the epidemic of 1916.

The form of apparatus that is used will naturally vary according to the training and taste of a particular surgeon, but the end of all of them is the same, prevention of deformity and protection against gravity.

One of the most vexing questions is that of when to allow the patients up. There is no doubt that overfatigue of a weakened muscle is the greatest obstacle to its recovery. On this theory Dr. Lovett was accustomed to keep the patients off their feet indefinitely, while they had massage and muscle training. I feel myself, however, that the mental attitude of the patient is of the utmost importance, and that the depressing effect of such prolonged inacivity upon the patient must outweigh its benefit to a given muscle. Provided the affected muscles are properly protected I cannot see that a small amount of exercise can be harmful. Even when accomplished only with the aid of braces and crutches the power of independent locomotion is of tremendous psychological value to the patient.

We have now arrived at the controversial phase of the disease. What is to be done during the two year period that we have agreed to regard as that of potential recovery? Shall the patient have massage, muscle training, water borne exercises in a pool, various forms of electricity, chiropracty or osteopathy? I think the best thing to do is to fall back upon pathology. I take it for granted that a detailed muscular examination of the patient has been made. As the result of such an examination we know that certain muscles are completely, others partly paralyzed. We can by no means thus far devised affect the diseased area in the cord, except by the itch of ill advised activity to prolong its inflammation.

We have protected the remaining muscles by appropriate apparatus against the harmful effects of deformity and overfatigue. We know that paralyzed muscles when completely neglected atrophy, become stiff and lose their tone, and that when a bone no longer functions in weight bearing it loses its calcium. Obviously, therefore, the muscles must be kept in the best of condition against the possible return of nerve power. Anything, therefore, that preserves their blood supply and is not so violent as to cause harm is beneficial.

In deciding what more complicated method of treatment shall be used we must think again of the pathology. I have heard it said that by so-called muscle training nerve impulses from the brain could be trained to leap around, as it were, the damaged anterior horn cell, and arrive at their muscular destination by a different peripheral nerve. This theory appears to me to rest more on wish fulfillment than on physiology.

While we are told that no man by taking thought can add a cubit to his stature, we also know that by taking appropriate exercises we can increase the size of a muscle. Suppose that half

my biceps muscle were paralyzed, I might by careful, persistent training build it up until the remaining half could do the work of the whole Muscle training, under water exercises and electricity all seek this end I personally feel that the voluntary exercises, in which the patient's own brain is the activating force, are of far more value than the passive

Water-borne exercises are certainly the most logical form of treatment This at once brings up visions of inaccessible swimming pools and costly expert therapists There is, however, a bathtub in practically every home This may be filled with water at from 85-90°, a little salt put in the water to increase its buoyancy, and the child placed in the tub and allowed spontaneously to move his limbs If the doctor will then observe him carefully, he can, without particularly expert knowledge on his part, devise exercises for the affected muscles

I feel, particularly in the early stages of the disease, that electricity is dangerous The only form of electricity that has been proved of any value is a form of current, such as the Bristow coil, which actually produces muscular contraction Unless in the hands of a real expert, who knows how to stimulate one affected muscle at a time, there is great likelihood that all the muscles of an extremity will be stimulated at once, thereby cultivating the strong at the expense of the weak Even an expert is apt to be carried away, and contract a muscle twenty times or more, when four or five contractions would be all that were indicated

I wish to emphasize in connection with both these forms of therapy that the greatest of all dangers to a convalescent muscle is overfatigue from any cause If there must be a choice between the two evils too much treatment is far more harmful than no treatment whatever

I think this an appropriate time to call the attention of the profession in general to two facts —that the patient must not be sacrificed to his disease and that the family must not be sacrificed to the patient A patient is not likely to be greatly soothed by exercise in the relaxing luxury of a pool if it takes him two hours in a crowded bus to get to the hospital, and two more to get home again Also the paralyzed patient is but one unit in a family and sacrificing all the family resources to send him to a certain specialist or away from home, perhaps, for a given form of treatment is mistaken kindness, and does most harm to the recipient himself From the very beginning emphasis must be placed upon making the patient independent, and not dependent upon the ministrations of his family or friends

We now come to the third stage of the disease We assume that every legitimate form of treatment has been tried, that a certain amount of improvement has been gained, but that it is agreed by all, including the patient, who is the best judge, that it has come to a standstill Twenty-five years ago the future would have been said to be hopeless Today I know of no field in which surgery offers a more brilliant promise Except in the most extraordinarily bad cases surgery has supplanted apparatus Spine fusions do away with back braces, and various tendon transplantations and stabilizing operations take the place of braces for the legs and feet I have seen a number of cases of paralysis of the lower extremities which required the persistence of but a single muscle, the gluteus maximus, to enable the patient after various operations to walk without apparatus The existence of less, but still severe degrees of paralysis may by surgery be entirely disguised Nor is there any limit to the time at which such improvement may take place The most spectacular case I ever personally treated was a man of fifty two years old who had been paralyzed for thirty eight years and during those years had never walked He now gets proudly about on braces and crutches Some of you may think that the ability to get about with braces and crutches is not such a great achievement To a person who has had all his life to be carried from place to place, the ability to get up and watch a fire engine going by means in health, contentment, happiness, and general well being a great deal

I should like to end this paper upon a note of optimism The disease this year is not nearly as severe as in 1916 I have not seen for years the terrible deformities that I saw then all over the State of New York Surely such an improvement must mark a beginning in the education of the public and the medical profession Once they have an understanding of the nature of the disease, when it no longer seems the utterly mysterious thing that it does now, the people will no longer rush frantically from quack to quack sacrificing the fortunes of the family to anyone who promises a cure

The public should know that only a small proportion of patients who contract anterior poliomyelitis are paralyzed at all Of those paralyzed a large proportion get well Of those who do not, the ones who are faithful and systematic in following the doctor's orders over long periods of time may be greatly improved Owing to the replacement of braces by surgery only a very small number need expect to look, feel or act like a cripple

THE NATURE AND TREATMENT OF NON-SPECIFIC ULCERATIVE COLITIS*

By ASHER WINKELSTEIN, M.D., NEW YORK, N. Y.

From the Medical Department, Mount Sinai Hospital, New York City.

Introduction

THE term "colitis" is frequently used in an incorrect sense by the physician and the layman. Colitis signifies definitely an inflammation of the colon and the term should not be applied to gastro-intestinal disturbances of a functional nature.

The type of colitis with which we are concerned today, ulcerative colitis, is a special form of the inflammatory colitides. This remarkable disease, first described as an entity by Sir William Wilks in 1875 and William Hale White in 1888, is variously known as colitis ulcerosa, colitis purulenta, colitis gravis, idiopathic colitis, chronic bacterial colitis, and chronic ulcerative colitis. We prefer "non-specific ulcerative colitis" as being the most descriptive title.

The subject of this disease is of great importance for many reasons. It is a fairly common and a very serious malady. Apparently, it is increasing in frequency. A correct differential diagnosis is essential for proper therapy. Finally, every single feature of the disease has given rise to disputes which are, as yet, for the most part, unsettled.

Statistics

Let us consider the statistics of this disease. The Mayo Clinic reports 675 cases in a ten-year period. At Mount Sinai Hospital, we see an average of 40 cases of the serious type a year. Apparently, it is not an uncommon disease.

Most of the patients are from 20 to 40 years of age. Helmholtz, however, has described it in young children. I have seen four cases in children during the past year. The sex distribution is equal.

The mortality is higher than in typhoid fever (15%). Logan of the Mayos gives 27%, Strassburger of Germany 40%, Lockhart-Mummery 40%, and at Mount Sinai Hospital our figure is 18%. These figures, of course, represent the mortality of the serious hospitalized group. It is surely a disease to be dreaded.

Pathology

Let us next discuss the pathologic features of ulcerative colitis.

It is generally agreed that it is an infection; whether primary or secondary, we will discuss later. Also, it is agreed that the process commences, in most instances, in the mucosa of the rectum and sigmoid. It is confined to the colon —rarely extending into the terminal ileum.

In the severe cases, the entire colon is involved whereas in the milder cases, only the rectum or sigmoid may be involved. Occasionally the process is higher up, leaving rectum and sigmoid free.

There is an interesting group where the inflammation occurs in the form of localized masses, called "non-specific granulomas," particularly in the cecum and the flexures. They are probably, in many instances, the result of localized ulcerative colitis.

The evolution of the lesions is as follows—first there is edema and congestion of the mucosa; then myriads of minute superficial ulcers form—we have not seen the miliary abscesses described by Buie. Later, large, coalescing, deep ulcers appear, leaving scarcely any normal mucosa. It is at this stage that certain severe complications, namely, perforative peritonitis, fistulae, and polypi occur. When the disease heals the mucosa appears normal, atrophic, or, rarely, scarred. Polypi, strictures, and fistulae may be among the unfortunate sequelae.

I shall now mention briefly the complications of the disease which are not infrequent in the severe cases.

Complications:

Local	Massive Hemorrhages (infrequent) Polyposis (13%) (17 cases of malignant degeneration reported from the Mayo Clinic) Stricture (recto-sigmoid) Fistulae (recto-vaginal) Perforation (3%) Inflammatory masses Peri-rectal suppuration
General or Distant	Bacteremia—Endocarditis Arthritis, neuritis Bucco-Pharyngeal ulcers Skin lesions (erythema nodosum especially) Eye lesions Parotitis

Clinical Features

Among the clinical features only the most important will be mentioned briefly.

It is a chronic disease—often lasting years—I have a young woman under observation now with continuous ulcerative colitis for eighteen years. It is, like peptic ulcer, essentially a disease with exacerbations and remissions. The remissions, often sudden and spontaneous (one must exercise care in the interpretation of therapeutic results) may be very short or very long—in some instances 5, 10, and even 20 years. There are mild, moderate, and severe types—often with sudden transition from one to the other.

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 2, 1931.

What does a typical severe case present? A diarrhoea (five to thirty movements daily)—the movements, often small discharges, contain blood, pus, and mucus chiefly—septic fever, emaciation, dehydration, anemia, and, some of the complications already mentioned. Some mild cases have only diarrhoea. Some rare cases are constipated. The colon may be badly diseased without fever and complications—even with general well-being. The colon may show only congestion and edema and yet the patient may be very toxic. In other words, although usually the clinical features and the pathologic appearance correspond, it is not uncommon to encounter a lack of parallelism. Let us assume that we are confronted with such a patient—i. e., one who complains of a more or less chronic bloody diarrhoea, how does one establish a diagnosis of non specific ulcerative colitis?

The *stool* examination is of utmost importance—it is usually a sanguinous and foul fluid—microscopically, it is almost pure pus and blood. One should look at the stool daily—it is an excellent guide in the course of the disease.

Next comes *sigmoidoscopy*. This is not used enough by the general practitioner. As Hurst puts it—"would one diagnose and treat tonsillitis without looking at the tonsils?" It is important to look at the mucosa. One sees, early, congestion and edema, then myriads of tiny superficial ulcers presenting a granular appearance, and later, large, deeper ulcerations. Of course, polypi are seen—they may appear and disappear. Two sigmoidoscopic points are of importance: (1) in my opinion, it is impossible to differentiate the sigmoidoscopic features of non specific ulcerative colitis from amoebic and bacillary dysentery, and (2) there is often a striking lack of correspondence between the sigmoidoscopic picture and the clinical features—this has already been pointed out in the discussion of the pathologic features. Patients with non-specific ulcerative colitis, therefore, should not be discharged as well until the sigmoidoscopic appearance is normal.

The x-ray examination of the colon is also very helpful. We owe most of our knowledge of the radiographic points to Carman, Moore, and Weber of the Mayo Clinic. One must use the barium enema. What does one see? Well, early, only spasm or negative findings. Later, one finds that the colon is short, narrow, fills rapidly and the haustrae are missing. The edge may reveal nicking or feathering, indicating ulceration. The lumen may appear mottled, indicating polyposis.

A word of warning should be uttered—do not diagnose ulcerative colitis from the x-ray examination alone. It is very useful in following the course of the case, in localization and in the diagnosis of high lesions and complications.

Finally, before leaving this phase of the subject, a word about the differential diagnosis. Briefly, one may state it as axiomatic that in this climate, with rare exceptions, a chronic bloody diarrhoea is either non-specific ulcerative colitis, amoebic dysentery, bacillary dysentery, or carcinoma coli. In the case of amoebic and bacillary dysentery, the differentiation, of course, is purely a laboratory one. One must, however, bear in mind the fact that despite negative laboratory examinations a patient may have, and with fair frequency does have, amoebic or bacillary dysentery.

WHAT IS THE CAUSE OF THIS DISEASE?—Several questions arise at once.

1. Is it primarily an infection? The answer is unknown—it may be first a neurotrophic disturbance, a toxic-excretory injury, an avitaminosis, or another acute infection (bacillary or amoebic dysentery, for example) and, then, secondarily, a secondary infection of a sensitized bowel by the normal bowel organisms.

2. Is it caused by the Diplococcus of Bargen? In a series of papers from 1924 to the present, Bargen of the Mayo Clinic has described a causative organism, present in 90% of the cases, with positive animal reproduction of the disease, with a vaccine and culture filtrates helpful in therapy, with a curative crude horse serum and finally, a curative purified horse serum. This work, exhaustive and painstaking, merits serious consideration. Of course, one hopes that he has solved the etiologic problem. Certain doubts naturally arise—isn't this organism, also, merely a secondary invader? Is it clearly differentiated from the enterococcus and other normal inhabitants of all normal bowels? Is the experimental and serologic evidence complete enough to establish it, according to strict bacteriologic criteria, as the causative organism? Have the therapeutic claims been substantiated? Certain opponents of his ideas, particularly T. R. Brown and M. Paulson of Johns Hopkins Hospital, have been very blunt in their criticisms. They state (1) that only one-third of the cases were cultured, (2) agglutination methods are unsatisfactory, (3) the experiments lacked proper controls, (4) the characteristics of the organism were not constant in the various reports, (5) Paulson obtained the same rabbit lesions with normal organisms from the bowel of normal people.

3. Is this disease acute or chronic bacillary dysentery? In favor of this view, sponsored chiefly by Hurst of London, is the following:

1. Pathologically, the lesions in both are identical.
2. The disease may start in acutely, as in bacillary dysentery.
3. Occasionally, dysentery organisms have been found.
4. Occasionally, one sees excellent results with anti-dysentery serum.

Opposed to this view are the following:

1. The sporadic nature of non specific ulcerative colitis

2. The onset is usually insidious in ulcerative colitis.
3. Scarcity of bacteriologic and serologic evidence.
4. The higher mortality in ulcerative colitis.

Recently, Dr. Gregory Shwartzman and I have been accumulating evidence at the Mount Sinai Hospital which indicates that some of the cases, at least, are acute or chronic bacillary dysentery. In the past six months, four cases yielded either Flexner or Shiga organisms when the fresh stool was cultured. The organisms were identified by agglutination and cross-absorption.

One may conclude, however, that, as yet. the etiology of this disease is not definitely known. Further work is necessary.

A brief résumé of the therapy in this disease will now be outlined. Whether or not amoebae are found, every patient should have a course of Emetine (grs. 1 daily intramuscularly for ten doses). With this exception, for the first ten days, the therapy should be general and non-specific. This is a control period.

The medical therapy should consist in:

1. In bed—local heat—calcium administration —possibly viosterol.
2. Diet: non-residue, low protein, with high carbohydrate-push fluids, salt, and vitamins. Maintain the nourishment as in typhoid!
3. *For the diarrhoea*—deodorized tincture of opium—morphine occasionally.
4. Transfusions—of great value. They should be repeated and large. They combat the anemia, supply fluid, and possible antitoxins. One sees occasionally a dramatic crisis after a transfusion.
5. *Specific measures* are of questionable value.
   (a) Autogenous vaccine—results are like those with other vaccines in medical therapy, i.e. disappointing.
   (b) Serum—in view of our experience, as well as that of Hurst and Crohn, we are treating some of the serious cases as bacillary dysentery. We are opposed to routine intravenous anti-dysentery serum as dangerous—we have seen two fatalities, perhaps attributable to anaphylactic shock. The serum should be given intramuscularly—25 ccs. b.i.d. for 6 doses at least. If one gets a result, he should not conclude that the case was bacillary dysentery. It may be only foreign protein shock. In some cases, to be reported, we have seen excellent results. In addition, in several instances, we have used repeated rectal instillations of a potent polyvalent anti-dysentery bacteriophage. Our experience here is too limited to permit of a conclusion. The method seems promising.
6. Local therapy with colonic irrigations and instillations: Because of the depth of the lesions and the possibility of spread, this type of therapy is of questionable value. However, it is our custom to use first as a control a one percent of bicarbonate of soda (in saline) colon irrigation daily—then one may use in the acute stages, acriflavine (1:4000) or Rivanol (1:1000). In the subacute and chronic forms, we find 1-2% tannic acid or silver nitrate (from 1:10,000 to 1:2000) more satisfactory. There is no convincing evidence that any form of local therapy is curative in any given instance.

SURGICAL TREATMENT.—The question of surgical intervention arises only in the serious cases. It should be used only when the case is a septic one and the patient going downhill rapidly. Nice therapeutic judgment is necessary here. A well-known Boston surgeon says "operate at the end of one week"—Stone of Johns Hopkins says "six weeks." It is really a question of individualization—however, one should not wait until the patient is moribund. The high mortality in the operations may be the result of waiting too long. The following operations have been used and may be discussed.

1. Appendicostomy and cecostomy—not good since the fecal stream is not diverted.
2. Colectomy—too dangerous.
3. Ileo-sigmoidostomy—this excludes two-thirds of the colon—the lower portion can be treated locally. Perhaps this should be tried more often.
4. Ileostomy (Brown of St. Louis) the best operation—often dramatically life-saving—it saves a life but does not cure the disease —the disease continues. If one removes the ileostomy, the disease recurs. Recurrences of moderate severity are not uncommon even in the presence of an ileostomy.

CONCLUSIONS:

1. Non-specific ulcerative colitis is a frequent and serious malady.
2. The etiology is as yet not definitely established.
3. Because of the difficulty of excluding amoebic and bacillary dysentery, therapy should be instituted against both of these diseases.
4. Therapeutic controls are essential because of the spontaneous remissions.
5. If adequate medical therapy fails, surgical treatment, preferably ileostomy, should be instituted early.

PREVENTION OF NERVOUS DISORDERS; A COMMUNITY PROGRAM*

By ALBERT B. SIEWERS, M.D., SYRACUSE, N. Y.

IN every community problems arise and multiply and eventually the community arises to do something about these problems. This is certainly bound to be the case if the difficulty grows beyond the capacity of the individual or his family to handle. The two main ways by which a community endeavors to meet its problems are the introduction of skilled specialists and the gradual education of the members of the community themselves. In an ideal situation, both ways are employed from the beginning and in any situation they are finally necessarily used. In this paper we are considering no community in particular and likewise no specific psychiatric program, but rather communities in general and, psychiatric programs in general with the general aim of having the psychiatric point of view becoming an integral part of the community. In his better moments the aim of the psychiatrist is to do away with the necessity for himself.

In the field of nervous disorders, which includes for practical purposes the problems of behavior, there has been for a long time community organized means, however imperfect and inadequate, for handling of its special problems. These means, which have long been in existence, are: The State Hospital, The State School for Mental Defective and the so-called Reformatory or Penal Institution.

Until quite recently one could safely say that the best knowledge and training in the field of nervous or behavior disorders was being applied largely in the field of Criminology and Mental Defect rather than to the more preventive aspects of the problem child in the school, whether preschool, grade school or high school. This in spite of the fact that admittedly less can be done and less is expected in the fields of mental defect or deviation than one can do or expect in the field of prevention. We have been putting the "cart before the horse."

The trend of the community in handling its problem of nervous or behavior disorders has been the same as the trend in other medical and social fields. The steps have been:

1. Emphasis on the improved care of the cases in Institutions.

2. Betterment of after care and other forms of follow-up, leading to the establishment of clinics of one kind or another whose aim was prevention.

3. Prevention has meant a change from rigid fixed ideas and technics in treatment of behavior disorders, to a dynamic growing or revolutionary conception of all the probelms in this field.

This dynamic conception has brought the psychologist out of the laboratory into direct contact with individuals. It has brought out, as the greatest aid to understanding and treatment, the psychiatric social worker and, it has changed the psychiatrist from a physician, who had a lot of queer pigeonholes and queerer labels, to one who wonders, observes, listens and tries to understand and interpret, and then, sanely and soundly, direct measures for relief.

The psychiatrist or at least the psychiatric point of view may be an important factor in guiding many of the normal contacts of growing children, but in all too many instances it plays no part, because of the over-emphasis in the past on the child's physical well being alone. It might be well to list a few of these contacts and make an attempt at evaluation of them. First the Home.

There is a growing realization that the ability to have children does not necessarily bespeak the ability to bring them up properly. This point of view has developed through community education and though this has been done from a standpoint of physical rather than mental health, it nevertheless applies to both. Physical and mental well being should not be stressed as separate, after all, the individual is a psycho-physical unit. Parents are made aware of feeding difficulties and their prevention as well as the prevention of colds, diphtheria, and the like. But all too often the development of desirable habits and the prevention of undesirable habits is left out of the program until the child is ready for school. Parents are lulled into inactivity by the idea that children will out-grow undesirable traits or shed them like an old coat when they enter school. Here, then, is the opportunity for the community through the Obstetrician, the Pediatrician and the Public Health Nurse, to begin work with the child as soon as he is born. And not only begin with the child; it is the parent with whom we must deal.

Here we are not looking for direct instruction in how to solve each individual emergency situation as it may arise. Too many parents believe that a child training expert exists to tell the mother definitely what to do when her child embarrasses her by having a temper-tantrum in a department store, or when he refuses to eat the fresh greens she has so carefully provided for him. What the expert and those interested in helping him are trying to create is a parental attitude which is sufficiently understanding of mental hygiene principles that it can recognize this behavior as symptomatic of a childish difficulty once preventable, now needing at this stage of development a redirecting. We said one should "begin work with the child as soon as he is born.' That is not early enough!

* Read at the Annual Meeting of the Medical Society of the State of New York, at Rochester, N. Y., June 4, 1930.

The importance of the early years of a child's life as a most plastic period has been accepted and taught for some time. Many experts in psychiatric fields insist that most habit patterns are laid down by the sixth year. As a result, work with and interest in the pre-school child is increasingly evident. Through well organized nursery schools, mother's study groups, and sometimes as a part of the school health program of the community's department of health, there is developing a more objective and constructive consciousness of the importance of parent-hood. By the use of nursery school technic we can do much toward forming in children the habits of regularity, reliability, self-reliance, obedience, good habits of eating and sleeping, and the ability to get along with others. And with the proper psychiatric set-up much can be done to prevent or correct undesirable habits of eating and sleeping; temper tantrums; jealousy; enuresis; thumb-sucking; masturbation; lying; and stealing. What this "psychiatric set-up" shall consist of has been up to this time a matter of experiment and of suiting the service to the community needs and demands. Frequently the needs and the demands do not coincide. Here again we have our opportunity for community education. The basic fact that some such set-up is essential to any community is, however, past the stage of experimentation.

School:

Schools are primarily educational and are organized for the intellectual development of the child. In addition, the majority of schools have a well organized medical service which is almost entirely absorbed with the problem of the physical well-being of the child. This means that the emphasis is all too heavy on the physical and intellectual development while the emotional development has been neglected or misunderstood. The aim of the educator and the psychiatrist should be identical, that is, to produce in the child a good adjustment with his environment and to develop in him personality traits which will help him to get along in the world as one of the happily adjusted.

Since demonstration child guidance clinics have shown what the team of psychiatrist, psychiatric social worker and psychologist can contribute to the solution of behavior problems, there is no question that they should go a step further and bring their special knowledge and technic to aid with the development of the normal child. The aim then, which we hope for in our educational system is the personal development of the child rather than the making of high grades, through an attempt to surround him by those influences which will help him in emotional control and will establish such mental habits as make for successful living. Leading educators are, of course, aware of the practicability of this point of view. When those parents who remember school as consisting of only the three grim R's can similarly adopt this attitude where facilities exist, and demand them where they do not, we shall have further progress.

This would make for conservation of Mental Health. Psychiatric help would then be available and given to all children in the school system, and we would not be waiting for acute episodes or definite behavior problems to arise. Problems might be anticipated and prevented.

It is beyond the scope of this paper to consider the various behavior problems which arise in the schools but we can consider more specifically what the educators' acceptance of these aims might mean. For example: In all probability the problems which have been and are most readily and thankfully turned over to the psychiatrist, are the problem of truancy. In cases of truancy as with other behavior problems, study shows the great variety of contributing factors, which if allowed to continue, may lead to delinquency or in extreme cases, to psychoses. One of the hopeful signs of the day is the increased readiness among lay people to study each problem individually. For who can generalize as to whether the emotional factors may be varying phases of sibling jealousy, unfortunate comparisons with other children, or too great emphasis on high grades, due to exaggerated parental ego drive. Misunderstanding on the part of the teacher or school principal may add to the child's difficulty. The truant or other behavior problem may be a day-dreamer who finds the school interferes with his day-dreaming and forces reality too harshly upon him, or he may be wrongly placed in his grade, or again, he may be a child who finds his greatest satisfaction in the attention he receives by going against the rule. The day-dreamer whose wandering attention is a thorn in the flesh of his teacher might be readily referred to the psychiatrist, but the other type of day-dreaming child whose school behavior is examplary, may be too easily overlooked as a behavior problem. It is this quiet type, often the most apt student, never giving trouble in the classroom, which we believe sometimes to be pre-dementia praecox—if we may be allowed this anticipatory term. Much can be accomplished in bringing this type of child to the every day world by intensive work on part of the psychiatrist and the visiting teacher or school counselor, who is trained as a psychiatric worker.

"Nothing succeeds like Success" is an old proverb and "Nothing so quickly becomes a habit as Failure" should be added to it. With our attention to personality development, as well as to problems, there must be attention to proper grade placement to prevent feelings of inferiority and with them the habits of failure. Special classes must be provided for those who cannot carry on in the regular grades, but this does not mean just classes with less book work and more hand work.

It means classes directed by a teacher, who has some feeling for the development of the individual pupil as a unit of physical, intellectual, and emotional make-up. These special classes should serve several purposes which have definite places in a program of prevention.

Directly:

The backward or defective child can be removed from the regular grade where competition is always with those quicker than himself, to the special class where he competes with like capacities, and still learns things which will help him get along in the world. In this way we may prevent later tragedies of poverty or delinquency and relieve the burden of the State Institution.

Indirectly:

A backward child requires much more of the teacher's time and energy than a normal one. Therefore the removal of the backward one gives the teacher better opportunities to teach and provides for each teacher a more homogeneous group.

In the future one can readily see the necessity of extension of the work of the psychiatrist and the visiting teacher, not only with the pupils but with the teachers. The teachers already on the job should be shown in every way the practicability of mental hygiene and helped to apply its methods. The teacher in the normal school and those to come should be given courses in mental hygiene. The most successful application of mental hygiene principals is to be expected if the teacher takes them with her as part of her teaching equipment rather than looking to their introduction by others than the educators themselves.

During the school age the time of the child outside of school hours is given to recreation or work (job) or both. The field of recreation offers one of the most fruitful means of influencing the child in the development of habits of self-reliance and sociability which we have come to know in adult life as efficiency and good sportsmanship. Yet, I believe this to be the field most neglected by educator and physician alike. True, we have boys' clubs and girls' clubs, but these are usually small units organized to take care of small limited groups. Here then, is a virgin field which in all probability will have to be pioneered by the groups already in the field with the help of other organizations interested in youth and filled with civic pride. Let some of these organizations underwrite demonstrations in recreation and it would not be long before the community would recognize that planning and really skilled workers in this field are a necessity.

Camps:

This brings us to a subject which is constantly becoming more and more important and which at this season is particularly apropos—the summer camp. The ideas and ideals of a large part of the community in the matter of camps can be expressed by contrasting two outstanding types.

1. The camps based on the idea that removal from the noise of the city to God's Great Outdoors where the grass is green, the air fresh and the food and water plentiful is in itself a great constructive experience for the child. The partisans of this type of camp feel that having provided one of natures beauty spots and a good cook, the children can be trusted with little guidance to reap a harvest of good.

2. That type which accounts for every minute and does everything on schedule, e.g., arise at 6.30 put on bathing suit, swim. 7.00 return to dormitory, make beds. 7.15 sing. 7.20 breakfast. 7.40 clear tables and so on. Hikes on Tuesdays, Thursdays, and Saturdays at 8 A.M.

Of course, some private camps are run on a system which is designed to bring out desirable treaits with small groups, projects, etc., but communities and their agencies have been reluctant to accept innovations from the two types. Rademacher in his Cleveland experiment with a long term camp as treatment for behavior disorders gives just a hint of what we might accomplish here by the introduction of a psychiatric point of view into this branch of the field of recreation.

Jobs:

I feel it is beyond my limited powers to discuss child labor laws and hope it is really beyond the scope of this paper. That the community has a responsibility here is unquestionable, and it may be found that the psychiatrist and his associates have something to contribute here as they have contributed in the handling of cases of juvenile delinquency by the courts.

Besides these inventable contacts there are a number of others which might be considered. The sick child comes into contact with clinics and hospitals, with physicians, nurses and social workers. In these medical fields the education has not been able to keep up with psychiatry, but much is being done to catch up. Psychiatric hospitals and psychopathic wards in general hospitals are being established. Psychiatric services in dispensaries and hospitals are being enlarged and increased. Medical colleges are re-arranging their courses in psychiatry. Nurses' training schools have in large numbers established affiliation with State or other hospitals for mental disorders, and schools for social workers are emphasizing family rehabilitation and the handling of individuals rather than the distribution of relief. With these powerful forces at work the science of psychiatry grows apace as all infants grow and the conservation of mental health really becomes a community project.

NEW YORK STATE JOURNAL OF MEDICINE

Published semi-monthly by the Medical Society of the State of New York under the auspices of the Committee on Publication.

CHARLES H. GOODRICH, M.D., *Chairman*.....Brooklyn CHAS. GORDON HEYD, M.D.....New York
DANIEL S. DOUGHERTY, M.D.....New York

Editor-in-Chief—ORRIN SAGE WIGHTMAN, M.D.....New York *Executive Editor*—FRANK OVERTON, M.D.....Patchogue
Advertising Manager—JOSEPH B. TUFTS.....New York

Business and Editorial Office—2 East 103rd Street, New York, N. Y. Telephone ATwater 9-5056

The Medical Society of the State of New York is not responsible for views or statements, outside of its own authoritative actions, published in the JOURNAL. Views expressed in the various departments of the JOURNAL represent the views of the writers.

MEDICAL SOCIETY OF THE STATE OF NEW YORK

Offices at 2 East 103rd Street, New York City. Telephone ATwater 9-7524

OFFICERS

President—WILLIAM D. JOHNSON, M.D.....Batavia
First Vice-President—CHARLES C. TREMBLEY, M.D..Saranac Lake
Secretary—DANIEL S. DOUGHERTY, M.D.....New York
Treasurer—FREDERIC E. SONDERN, M.D.....New York
Speaker—JOHN A. CARD, M.D.....Poughkeepsie
President Elect—CHAS. GORDON HEYD, M.D.....New York
Second Vice-President—HARRISON BETTS, M.D.....Yonkers
Assistant Secretary—PETER IRVING, M.D.....New York
Assistant Treasurer—JAMES PEDERSEN, M.D.....New York
Vice-Speaker—GEORGE W. COTTIS, M.D.....Jamestown

TRUSTEES

JAMES F. ROONEY, M.D., *Chairman*.....Albany

Annual meeting, Buffalo, May 23-25, 1932

OPPORTUNITIES, RESPONSIBILITIES AND OBLIGATIONS

When does an opportunity become an obligation?

This is not a mere problem of abstract reasoning; it is a practical question which confronts the medical profession today.

Doctors are not entirely satisfied with the methods and results in the practice of medicine. They are unanimous in their opinion that they are surrounded with evident opportunities to increase their capabilities and sphere of usefulness.

Many physicians feel that the major share of responsibility for providing better medical service rests with the people themselves, for they are ready to give what the people demand and appreciate.

A minority group of doctors feel an obligation

to assume a leadership in all forms of medical service, even that of educating the people to assume their proper share of the burden

Opportunity, responsibility and obligation are degrees of the same mental attitude toward medical service Medical leaders seek to reach the doctors who are watching opportunities listlessly from the side lines, and are striving to inspire these passive physicians to do something active, even if it be only to stand up and cheer for the new methods of progress

The mental processes of every doctor pass through three stages in solving medical problems

1 The stage of *opportunity* or recognition that conditions are not entirely satisfactory Every doctor feels this way toward most medical problems

2 The stage of *responsibility* in which doctors here and there say, "Why don't some one do something?"

3 The stage of *obligation* in which a few leaders say, "Let us get busy"

Physicians recognize two classes of obligations

1 Those applying to the doctors themselves

2 Those applying to the patients or their families

The essential obligation resting on every doctor is that of keeping up with medical knowledge A further obligation is that of seeking the advice of a specialist when his own knowledge is uncertain A whole group of further problems suggest themselves, such as

Graduate education,

The qualifications of specialists,

The ready means of securing the services of experts,

The availability of consultants in hospitals and private practice, and

Group practice

Physicians are earnestly seeking practical solutions of all these problems, and it may be truly said that the services which individual doctors are giving to their patients are more scientific and conscientious than ever before

If the doctors are under obligation to render the best possible service to their patients, they cannot fulfill that obligation unless the patients cooperate with them Failure of a patient to cooperate with a doctor is the result of two causes

1 Unwillingness

2 Inability

Each party, the doctor and the patient, is inclined to blame the other for lack of cure, but after the doctor has done his best to render efficient medical service, the further responsibility rests upon him to diagnose the exact cause of the patient's failure to seek an efficient remedy

When the doctor's diagnosis is unwillingness on the part of the patient, the remedy is *education*. The individual doctor is under obligation to instruct the patient and family regarding the illness, the measures for its cure, and the means for preventing its recurrence or its extension to others

To give these instructions to every individual patient is a very large task for which the busy doctor has not sufficient time The doctor of a decade or two ago considered himself excused from further responsibility for his patient if he diagnosed the underlying causes of his patient's failure to be ignorance or inability Every doctor today sees the opportunity to educate the patients, an ever increasing number realize their responsibility to give that instruction, and a few medical leaders have a keen sense of obligation to give that instruction

Talk about missionary efforts on the part of churches! Doctors are altruistic missionaries who destroy their own livelihood in direct proportion to their success in educating people to keep well They are not only home missionaries instructing their own people, but they feel the obligation to minister to people of other lands, because the plague in China or cholera in India is the direct menace to the health of our own people as well as the cause of world-wide economic disturbance

Among the greatest advances in the practice of medicine in recent years has been the growth of the spirit of cooperation among doctors, among their patients and between the medical profession and the public The individual doctor can do comparatively little in educating the individual patient for his instruction begins only when sickness is already present Nor can the individual patient and family correct their defects of ignorance or inability to cooperate after disease has come upon them No argument is needed to prove the necessity of collective action of individual doctors and of concerted measures by the people

Physicians throughout the civilized world have their medical societies which represent the standards of individual doctors The fundamental organization is the county medical society to which all physicians are eligible, except that small minority who are so intensely individualistic by temperament that they cannot live in peace with their fellow doctors There is a very real sense in which the county society practices medicine Its officers and committees promote the establishment of hospitals and public health nursing, and advise the authorities regarding their conduct in public health matters They also carry on campaigns for educating the people so that they will be ready to cooperate with the family doctor when sickness comes or is threatened The county societies set the standard of medical practice and of the relations of doctors to the public

People generally have little comprehension of the intimate connection of the county society with the practice of either private medicine or public health A board of education, for example, will choose the medical school inspector because he is

the family physician of some member of the board and not for his peculiar qualifications for the office; and when an officer of the county society asks why the society was not considered, the reply often is, "We didn't know you had a county medical society." Every individual doctor is willing that the medical society should decide the methods of conducting any form of public health work and of nominating the personnel that conducts the work. Such activities as these on the part of county societies is an essential part of the practice of medicine.

The obligation upon the people generally is of the same nature as that upon the family of a sick person. The people form one great family, and upon them rests the responsibility for providing the means of supplying efficient medical service to all. The responsibility rests primarily upon the sick person or family, just as it also rests primarily upon the individual doctor. But when the resources of the individual family or doctor are exhausted, the further responsibility rests jointly upon the public and the medical society to provide the remedial or preventive measures which the individual or family doctor cannot provide.

The elementary principle in public service, from acts of charity to the promotion of public works, is that the individual shall be held responsible so far as his ability goes. It is considered a calamity in New York State that the State or any organization should do for an individual what he can do for himself, be it in the line of finances, or civics, or morals, or health. Yet, there are a number of ways in which doctors expect the State to supply medical service—for example, the care of mental patients and the control of communicable diseases.

There are other ways in which doctors expect the State or other organization to supply part of the medical service, as in tuberculosis and laboratory diagnoses.

Then, too, there are ways in which doctors expect governmental bodies to reimburse physicians for treating those unable to pay for the service, as is the intent of the Welfare Law.

All these measures, a decade or two ago, would have been condemned as "state medicine;" but they are now advocated and planned by the Medical Society of the State of New York with a view of preserving the independence of both doctor and patient. Every doctor expects the State to build a cement road over which he may drive as he calls on his patients. It is equally logical that the doctor should expect the State to supply other missing links in the chain of medical service.

It is most encouraging that both the medical profession and the civic authorities have progressed from the state of seeing opportunities for efficient medical service into the state of realizing their joint responsibility for existing health conditions, and are now entering the stage of obligation to provide satisfactory means for bringing efficient medical service within the reach of every person.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

Biology Teaching: Twenty-five years ago the subject of nature study was being developed in the public schools of New York State. This Journal of November, 1906, contains a leading article on the nature study teaching by Dr. Helen C. Putnam of Providence, who studied the methods of teaching the subject in nineteen cities. The Doctor told of one experience in which the teacher taught young pupils about household insect pests, saying "Flies were found to be much more interesting and much more injurious than they had known. With hints from the teacher they collected eggs, watched them hatch into larvae, saw the fly come out of the pupa case. They mounted between plates of glass the egg, larvae, puparium, male and female flies. They learn through this work the life story of the fly; that it lays its eggs in manure heaps and dead animal matter; learn how numerous they are, what flies live on, how they carry filth and disease from sputum and other animal discharges to the next object they light on, which may be one's face or food. The children almost of their own initiative start a crusade against uncovered manure heaps, foul garbage pails and other common uncleanliness. They learn to believe in screens and covered food supplies. They learn, too, nature's method of killing these filth distributors by birds and toads."

After describing a study of mosquitoes, the author says:

"After similar practical methods the life stories and natural enemies of other household vermin were found out; roaches, fleas, bedbugs, buffalo bugs, moths, meal worms. They tried to figure the loss from damage to clothes and food, and to estimate the cost of extra labor.

"Collecting butterflies and wild flowers for study in schools has threatened in more than one locality to destroy beautiful and desirable species. But the collection of these household pests is a good riddance, while the knowledge gained is equally scientific, and saves health, labor and property. Many parents see a profit in this kind of nature study."

MEDICAL PROGRESS

The Treatment of Gas Gangrene—Henry Milch calls attention to the fact that gas gangrene is not so rare in civil practice as we are wont to believe It is a fairly common complication of so called "street accidents," and has been described as occurring after various operations In its treatment practically every known antiseptic has been tried and found disappointing Radical surgery, even including amputation, and the liberal use of a polyvalent serum are the only dependable measures at hand In an illustrative case, the author employed a polyvalent serum, similar to that of Larsen and Pulford, containing 4,000 units of tetanus antitoxin, 15 000 units of perfringens, 35,000 m l d of vibrion and 20,000 m l d of histolyticus antitoxin per 100 c c of saline A double dose was given directly after operation, and another 100 c c was administered after an interval of four hours The amount to be given and the interval at which it should be given must be determined by the clinical evaluation of the severity of the infection and the patient's response to the treatment Though the specificity of this polyvalent antiserum in definitive gas gangrene is not completely established, there is no doubt of its great value in reducing the mortality when used as a curative measure and in reducing the morbidity when used prophylactically Its greatest importance may lie in its use as a preventive measure Its administration should be advocated in all cases of street accidents, as well as pre operatively in patients suffering from arterial disease, diabetes, etc The prophylactic dose of polyvalent gas gangrene antitoxin is now being prepared in conjunction with tetanus antitoxin for commercial sale in this country It contains 15 units of tetanus antitoxin, 10 units of perfringens, 10 units of vibrion antitoxin, and is as easily administered as tetanus antitoxin alone In addition to the prophylactic use of sera, attention should be given to other auxiliary means of preventing the development of gas gangrene Shock, acidosis, and diabetes should be energetically combated Local, spinal, or gas anesthesia should be chosen in preference to ether or chloroform The use of the tourniquet should be forbidden even at the inconvenience of the surgeon—*Annals of Surgery*, June, 1931, xciii, 6

Pathogenesis of Metaplastic Diseases of the Hip ("Osteochondritis")—There can be no doubt, in the opinion of R Tiller and G Bousser, that the great majority of metaplastic affections of the hip are the outcome of initial malformations of this joint, varying from characteristic subluxations down to imperceptible anomalies of adaptation Sometimes they are secondary osteo-articular changes of which metaplasia is the cause and not the effect But it is unquestionable that a certain number of cases of osteochondritis—a minority—are the result of vascular phenomena which are not related to any question of articular morphology In the case of a spontaneous metaplastic disease, what occurs is apparently a repetition of a long slow series of minimal traumatisms, the mechanism of which appears to be as follows (1) A traumatism always produces a vasomotor disequilibrium (brief and negligible vasoconstriction followed by active and prolonged vasodilatation) (2) It may produce a more or less localized necrosis due to suppression of nutrition of one or several regions of the tissue, resulting in vascular ruptures or in small embolic processes The bone then becomes the site of local calcareous mutations as long as the vasomotor phenomena continue and until the mass of calcium set free is utilized The course of the metaplasia will be conditioned primarily by local vascular dispositions and secondarily by mechanical conditions of pressure, traction etc The indispensable condition is the vascular modification of the territory Local vascular troubles readily arise in the region of the hip joint, both because this joint has to sustain the entire weight of the body and also because the epiphyseal region of the head of the femur is more sensitive than any other to the slightest vasomotor variation, owing to the particular disposition of its principal afferent bloodvessels It is not always possible to determine the exact nature of the vascular disturbances, but it is easy to conceive the multiplicity of causes that may result in active hyperemia, and which may, in the presence of secondary mechanical maladaptations, produce metaplastic disease The osteochondritis may be capital, coxal, femoral, or of all three types combined These conditions, whatever their basic cause, constitute a well-defined pathologic entity They terminate, after a phase of resorption, in reconstitution of the joint in conformity with a new type, generally more or less abnormal—*Lyon Chirurgical*, May-June, 1931

Heart Disease and Pregnancy.—In discussing the risk of pregnancy in heart disease, Maurice Newman says the important point is to determine the efficiency of the myocardium The signs of myocardial deficiency which should be looked for in a pregnant patient are limitation of the response to effort, persistent crepitations at the bases of the lungs, edema of the ankles, en-

largement of the liver, and other signs of right-sided failure. If none of these signs are present patients with valvular disease may marry and become pregnant, but should be kept under observation. Persistent auricular fibrillation, signs of heart failure, or a history of failure of compensation from previous pregnancies or other causes, prohibit marriage and pregnancy. The essential principle in the treatment of pregnant women with heart disease is to guard against the onset of heart failure. The greatest care should be taken to maintain the general health and to avoid fatigue and excessive muscular exercise. Infections, such as bronchitis and influenza, which affect the nutrition of the heart should be guarded against. If the efficiency of the heart is maintained the majority of patients will go through pregnancy and labor without much added risk. When the heart is inefficient, the case should be regarded as medical rather than obstetrical. On no account should the pregnancy be interfered with until the heart failure has been adequately treated. At the onset of heart failure the woman should have absolute rest in bed, a restricted diet, and if the heart is fibrillating digitalis should be given until the rate is adequately controlled. Then sufficient digitalis should be administered to keep the heart rate within normal limits. Edema should be treated by restricting the amount of fluids, and giving digitalis and diuretics. If heart failure occurs before the end of the fourth month, abortion should be performed as soon as the heart has been adequately dealt with. In the later months of pregnancy labor should not take place until the heart failure has been overcome. When the child is viable either induction or cesarean section may be considered. The disadvantages of a general anesthetic can be eliminated by using spinal anesthesia, or morphine-scopolamine and local novocaine anesthesia. Labor should be conducted so as to give the heart the minimum amount of strain, particularly during the second stage. A close watch on the heart should be kept throughout labor, and if necessary heart stimulants should be given.—*Practitioner,* June, 1931, cxxvi, 6.

Obstetric Shock.—Although an alarming case, and especially a fatal case. of shock following labor is rare, Miles H. Phillips is convinced that the condition is worthy of close attention. Obstetric shock is the same thing as traumatic or surgical shock, it has the same causes and must be treated on the same principles. The distinction between primary and secondary shock must be kept in mind. Delayed or secondary shock may set in after a latent period, during which nothing obviously abnormal may be noted unless a routine blood pressure reading has been taken. The downward tendency of the systolic pressure gives the first warning of impending shock. The causes of shock are bodily fatigue from prolonged muscular exertion, cold from exposure, deprivation of food and water, sweating, hemorrhage, anesthetics, toxemia of pregnancy, infection, and emotion. This list of causes indicates the precautions to be taken in the prevention of shock. By proper antenatal management the woman should be brought to labor in good physical and mental condition. The second stage of labor should not be unduly prolonged. For the relief of actual pain and mental strain, the use of scopolamine in large doses, without morphine, has proved valuable. When the pains begin to distress the patient, whether in the first or second stage of labor, 1/100 of a grain is given, the dose being repeated in half an hour, and again at the end of the next half hour if required; then the same dose may be given at two-hour intervals. The author is also convinced of the value of this treatment as a preventive of shock. On studying blood pressure records, taken during the various stages of labor and immediately after, in scores of cases during the past fifteen months, he has been impressed by the fact that the fall of blood pressure has been less when scopolamine has been used. With the onset of shock further loss of blood must be prevented so far as possible. Bodily heat must be restored. Pain, anxiety, and restlessness should be relieved by the administration of morphine. The volume of blood plasma should be restored by the intravenous injection of 500 to 700 c.c. of gum saline solution, repeated if necessary. When the patient is in shock the repair of all tears should be postponed; particularly is there grave danger from the use of chloroform or ether. Phillips lays particular stress on the emotions as the cause of shock, and cites cases in which fear and anxiety afforded the only apparent explanation of collapse and death. Hence the woman should be helped to approach confinement with a mind free from anxiety and apprehension, and during labor measures should be taken to lessen mental strain.—*British Medical Journal,* May 16, 1931, i. 3671.

The Placenta as an Endocrine Organ.—The most recent investigations have shown, says L. Seitz in the *Münchener medizinische Wochenschrift* of May 22, 1931, that the placenta itself produces a hormone and thus enters directly into the state of equilibrium of the maternal endocrine system. It has become clear that, through the activity of this newly formed gland which begins to function when pregnancy appears, a hormonal displacement occurs and a new kind of hormonal equilibrium is ushered in, different from that which exists in the non-pregnant condition. The endocrine influence of the placenta and its reflex effect upon the maternal body must be regarded as a completely physiologic process, exactly adapted for the phase of gestation just as the action of the thymus is for childhood and the action of the ovary for puberty and sexual maturity. Its

effect is distinguished from these, however, in tempo, in quality and in quantity, in tempo, because the entire process is built up in 9 months and regresses in 2 3 months, in quality, because several increations are involved, in quantity because the active amounts are unusually large The disturbances attributable to an endocrine action of the placental hormone are of 2 kinds, those connected with endocrine activity itself, and those related to metabolism So far as we can now see, the chief effect of this hormone is to cause an increase of the other endocrine secretions already normally present, especially those of the anterior lobe of the hypophysis, of the ovaries and the thyroid, enabling the woman, unless of abnormally asthenic type, to go through pregnancy with undiminished health and in a state of general well-being Many women experience an improvement in their constitutional condition beyond anything they have ever before enjoyed The essential factor in these transformations in the maternal body is the thin limiting membrane formed by the chorion epithelial cells of the placenta These elements represent an endocrine gland in both the wider and the narrower sense of the word, through the action of which the entire glandular equipment of the maternal organism is stimulated to increased and perhaps more successful activity Growth processes are promoted in the various maternal organs and changes in metabolism and in organ function are cared for The sound and healthy female body bears these changes without great difficulty But in inferior persons disturbances of equilibrium in the endocrine system are brought to light, or there are changes in metabolism that lead to injury of organ function, with occasional fatal outcome

The Infrequency of Cancer in Egypt—The statistics for cancer in Egypt show such low figures, says Schrumpf-Pierron, that they suggest the presence of some special condition existing in that country Cancer is at least ten times less frequent in Egypt than in Europe Since 1918 when it was made compulsory to report the cause of every death in towns of over 5,000 population, the average mortality from cancer has been 0 23 per 1,000 population Cancer is responsible for only 6 in 1,000 deaths This relative exemption of Egypt is the more remarkable in view of the existence in this country of a special predisposing cause of cancer in bilharzia Of the small number of cancer cases (22) that Schrumpf-Pierron has observed among the native population (and his total observations in clinics include 7 040 patients suffering with all kinds of diseases), 7, or about one third, were of bilharzial origin Another striking fact is the very small proportion of cancers of the digestive tract, and of gastroduodenal ulcer Neither climate nor race accounts for the low cancer figures But Egypt presents a remarkable unity in the nature of its arable soil, which is watered only by the Nile and its canals This soil has an extraordinary content in magnesium, the minimum figure being 1 54 and the maximum 1 72 per cent The highest magnesium figure for any soil in France is that of Caen, which is only 0 1 per cent Thus the arable soil of Egypt is 15 to 17 times richer in magnesium than the most favorable spot in France In the filtered water of the Nile the magnesium content amounts to 6 to 22 mg per liter While this is not an exceptionally large amount, it is nevertheless many times the content reported by Breteau in four countries in which cancer is very frequent The ordinary Egyptian fellah however, prefers to drink the Nile water unfiltered, despite its heavy content of mud Even some personages of importance regard this unfiltered water as indispensable for their health The fellah also lives chiefly on vegetables grown in the soil abounding in magnesium Hence the small incidence of cancer in general and the infrequency in particular of cancer of the digestive tract suggest the strong probability that cancer may be related to a lack of magnesium in the system—*Bulletin de l'Academie de Medicine,* May 19, 1931

The So Called Precancerous Dyskeratoses—Discussing the nature of cancers of the type known as Paget's disease and Bowen's disease, which they place in a special class, G Massia and J Rousset say that although certain clinical and anatomical differences exist between these two affections, there are also striking resemblances in their origin and evolution Always it is the same zone of skin that is attacked Both diseases are characterized by epithelial hyperplasia of the prickle cells, and there is invariably an infiltration into underlying parts of the skin Both frequently terminate in cancer, and in both cases the cancer is of dyskeratotic type One is forced to the hypothesis that both affections are cancerous from the beginning, and that their origin cannot be other than an epithelium of the skin or the demi mucosae in such regions as the nipples, glands, vulva, anus, axilla, etc The particular point of the epithelium or its adnexa appears to be the neck of the sebaceous glands that are more specialized in such regions This hypothesis receives support from various considerations (1) Those cancers of the skin that are known at the present time have not at any moment of their evolution the type of the dyskeratotic cancers (2) In Paget's and Bowen's diseases the sebaceous glands have disappeared at the points where they are ordinarily abundant (3) Cells are found which have undergone sebaceous degeneration at points of the epithelium in the vicinity of typical lesions of these affections (4) It is quite possible that the dyskeratotic cells are only Malpighian cells undergoing sebaceous degeneration through cancerous excitation (5) Transpar-

ent cells are normally found in the cellular débris of the neck of the normal sebaceous glands of these regions. If this hypothesis is accepted, Paget's disease is a cancer of slow evolution of special points of the integuments, having the type of transparent cell, which is found normally at the level of certain sebaceous glands. It evolves by substituting for normal tissue cancerous tissue composed at some points of dyskeratotic cells, but at others, still of prickle cells. In the deep tissues this cancer produces a special type of tumor known as dyskeratotic cancer, formed of globes whose center is composed of degenerated cells, with desquamation upon the surface. Under certain conditions this tumor may evolve exclusively into the deeper tissue, without Paget's disease in the nipple or elsewhere. The evolution is similar in Bowen's disease, but this disease seems to have the ability to develop at any point whatever of the skin and of certain mucous membranes which have sebaceous glands.—*Journal de Médecine de Lyon,* May 20, 1931.

The Explanation of Paracusia Willisiana.—Heinz Diehl points out in the *Münchener medizinische Wochenschrift* of May 15, 1931, the inadequacy of the usual theory that paracusia Willisiana (the ability of many persons with otitis media and otosclerosis to hear conversation better in presence of a loud noise such as that of a moving train) is due to the loosening up of the pathologic fixation of the middle ear by the vibrations of the noise, so that sound transmission is facilitated. While the bones of the ear are no doubt moved by the noise, it is not true that they are made more easily movable. Any real loosening up of these ossicles by the vibration would have to persist after the noise ceases, but such is not the case. It is worthy of note that this paracusia is observed only when the noise is low-pitched. High-pitched sounds, on the contrary, disturb these very patients seriously. The explanation is quite simple. The energy of a sound wave in the air per second is proportional to the square of the amplitude and the square of the number of vibrations. If two sounds of different pitch have a like intensity at a given place in the air, their amplitude must be to each other as is the number of vibrations. A tone, for example, of 100 vibrations must have an amplitude 100 times as great as a tone of 10,000 vibrations if the intensity of both is to be the same. In disturbances of sound conduction—stapes ankylosis, otitis media—the amplitude of the vibration of the middle ear apparatus is restricted, so that it cannot transmit enough intensity of the sound when the tones are pitched low. A person with normal hearing instinctively talks louder when riding in a train. The noise of the train is usually composed of vibrations lying below 100. But these are precisely the vibrations that the patient with otitis media does not hear well. Under these conditions he easily hears the raised voice of the normal person addressing him. But he does not hear better in a medical sense nor in the sense of a paracusia Willisiana. In fact no such entity as paracusia Willisiana exists. The patient in question hears many high-pitched sounds more easily under these conditions, simply because he remains unaffected by the low-pitched sounds.

"Prominent Heel."—Paul Bernard Roth directs attention to a condition which appears to have escaped all mention in books. The patient complains of pain on the back of the os calcis on the outer side. On examination a localized swelling is observed about half-way down the os calcis, opposite the lowest limit of the insertion of the tendo Achillis. The swelling is tender on pressure, is very hard, and gives the impression of being due to a bony outgrowth. In a lateral roentgenograph, however, no bony prominence is seen, and one is led to think that the lump must be due to a thickening of the fibrous tissue covering the back of the os calcis, or perhaps to a thickening of the periosteum. This is obviously due to irritation by the back of the shoe not fitting the heel properly. Several cases which came under the author's observation suggested that the shape of the os calcis might be the cause, and that the shoemaker was not alone at fault. In *Cunningham's Anatomy* the posterior extremity of the os calcis is described as "of oval form and rounded surface." On examining several specimens in his own possession and forty in the College of Surgeons Museum, it was found that in 17 of the 43 ossa calcis there was a backward projection on the outer side. The author, therefore, believes that when one meets with a painful lump on the back of the heel, this prominence exists to an extra degree. Other conditions for which it might be mistaken, such as inflammation of the bursa beneath the tendo Achillis and apophysitis of the os calcis, must be excluded. The treatment consists in the avoidance of all pressure for one or two months. This necessitates the wearing of shoes with no backs, or with the back cut opposite the lump. A moderately high heel is theoretically of advantage, as it reduces any strain there may be around the insertion of the tendo Achillis. A walking shoe which meets the requirements in these cases is now in the market. The removal of the prominence by open operation is entirely uncalled for. As there is already a condition known as "painful heel," it is suggested that the condition here discussed may be named "prominent heel."—*British Medical Journal,* August 15, 1931, ii, 3684.

LEGAL

ACCIDENTAL INJURY

By Lorenz J. Brosnan, Esq.

Counsel, Medical Society of the State of New York

The conditions under which we live in this generation have led many prudent men to hold so-called accident policies. Since a large number of physicians are the holders of these policies, it might be interesting to analyze a few cases which have come before the courts in recent years in which there was a contest as to whether death or injury was or was not the result of accidental means within the meaning of the policy.

One of the leading dictionaries defines accident as "an event which under the circumstances is unusual and unexpected by the person to whom it happens." It has also been defined as "an event which proceeds from an unknown cause, or is an unusual effect of a known cause, and therefore not expected." It might be argued from the definitions above stated that a result would be accidental even if produced by means all of which and every detail of which were intended, provided the result which follows the employment of such means is different from the result anticipated. Let us examine some of the authorities and see how the courts have treated concrete cases which have come before them for decision.

A case which illustrates the principle that a death is accidental in its causes is where the act or thing which caused an injury is clearly accidental, and the injury sets in motion the forces which cause death. An example of this class of case is found in an accidental minor injury causing blood poisoning, which in turn causes death. An example of a more difficult case, where the cause was intended, is illustrated in a case decided some years ago by the courts of our State. The deceased had ridden on a bicycle over a rough road and a few hours after returning home suffered soreness in his abdomen, which rapidly increased to great pain. The next day a physician diagnosed his trouble as appendicitis and advised an operation which was performed, but the man died within three days. In a suit to enforce payment of an accident policy, medical testimony was to the effect that the appendicitis had resulted from the bicycle ride "because the 'psoas' muscle, the function of which is to flex the leg upon the body and rotate the leg and thigh upward, lies in close proximity to the appendix, and in such position that when brought into play, as by riding a bicycle, it necessarily rubs against the appendix, and there being 'coprolites or concretions' (hard substances about the size of a bean) in such organ, such rubbing or play of the muscle caused irritation resulting in inflammation, which weakened the walls of the appendix, caused it to rupture, thus permitting the contents of that organ to enter the abdominal cavity, causing appendicitis, septic peritonitis and death." The court ruled in favor of the insurance company on the ground that while the result was extraordinary and was accidental, the means which produced it were deliberately intended and carried out precisely as intended.

Another interesting case along the same line is one which recently came up in this State, likewise in a case to collect on a policy covering accidental death. A patient went to a dentist for the purpose of having a tooth extracted and was given oxide gas. After a slight quantity had been administered the patient stopped breathing and died. An autopsy was performed and revealed a condition of status lymphaticus, which experts called in the case stated to be a congenital state or condition of unknown cause, characterized by an abnormal persistence of the thymus gland in the chest. The expert testimony was agreed that a person the subject of status lymphaticus was liable to sudden death from slight causes, and it was brought out that the precise cause of such death was unknown to medical science. The appellate court ruled that under the circumstances, the administration of gas being exactly as intended by both the dentist and the deceased, there was nothing accidental in the means causing the death but only in the results occasioned by the means and, therefore, there was no accident covered by the policy of insurance.

A slightly different situation arose in a case which was very recently decided by the highest court of one of our nearby States. Suit was instituted to recover on an accident policy covering, among other things, the effects of bodily injury sustained by accidental means while riding in an automobile. It seems that the assured with two companions had started out on a country road on a cold December evening in a closed car. The car became mired in the mud so deeply that the chassis of the car rested on the ground, and efforts to get the car out of the hole by its own power failed. Passersby agreed to send a team of horses to drag out the car, so the two companions of the assured proceeded on foot, leaving the assured with the car to await help and while waiting he was to repair a tire. The assured

did not repair the said tire and help did not come promptly, but he apparently sat in the car with the engine running for warmth, for the next morning he was found dead in the car, the engine still running, with the windows closed. The medical examiner diagnosed the cause of death as carbon monoxide poisoning. On the trial of the suit to recover on an accident policy, a verdict was rendered for the plaintiff and the insurance company appealed arguing as a ground for reversal that the facts as outlined did not show death by accidental means. The appellate court ruled that the definition of accidental had been satisfied, even though it was argued that the assured by permitting the motor to run with the windows closed had voluntarily exposed himself to the circumstances which led to his death. In affirming the award to the plaintiff the appellate court said:

"The second ground of defense is that the insured's death did not result from the effects of bodily injury caused by accidental means. The term 'accidental means' has been variously defined."

The court cited with approval the following extract from another case:

"The significance of this word 'accidental' is best perceived by a consideration of the relation of causes to their effects. * * * An effect which is not the natural or probable consequence of the means which produced it, an effect which does not ordinarily follow and cannot be reasonably anticipated from the use of those means, an effect which the actor did not intend to produce and which he cannot be charged with the design of producing under the maxim to which we have adverted (the maxim that every man must be held to intend the natural and probable consequence of his deeds), is produced by accidental means. It is produced by means which were neither designed nor calculated to cause it. Such an effect is not the result of design, cannot be reasonably anticipated, is unexpected and is produced by an unusual combination of fortuitous circumstances."

The court continued:

"Counsel for defendant urge that the deceased voluntarily exposed himself to the danger which caused his death. We cannot approve such an idea. The odorless and tasteless nature of the insidious monoxide gas prevents any intimation that the insured knowingly remained in a place of danger. While it is true that without the engine running no carbon monoxide would have been produced, and so to the extent that he started the car and closed the windows, his acts were voluntary; but without some intervening factor the natural and probable consequences of his acts would have produced no danger. It was that intervening factor—in this case, the proximity of the exhaust pipe to the ground, causing the poisonous gas to come into the car—which produced the unnatural condition and danger, a factor which cannot be attributed to the deceased nor one which occurs or is anticipated in the ordinary course of events under similar circumstances."

These cases, defining the rights of the policyholder and the insurance company, are of interest to every holder of an accident policy.

CLAIMED NEGLIGENCE IN ADMINISTRATION OF ELECTRO-THERAPY

The defendant in this case, who specializes in orthopedics, was consulted by a young married woman who complained of pain in the lower part of her back. The doctor suggested treatment by electro-therapy, to which she consented. Using a standard brand of diathermy machine, he moulded two tinfoil electrodes, caused the patient to lie down on one of them which was applied under her abdomen, and placed the other on her back weighted down with a sandbag. In this position a twenty-minutes treatment was administered.

She returned on four subsequent occasions and received like treatment. When she returned for the fifth treatment, the doctor discovered that she had sustained a small second degree burn about an inch in diameter on the back, at about the place where the electrode has been applied. The doctor treated this with mercurochrome and a dry dressing, and proceeded to give her another treatment, attaching the electrode at a point away from the location of the burn.

The patient called for subsequent treatments over a period of several weeks and when the doctor last saw and treated her the burn had entirely healed. The doctor contended that his machine was in perfect order and that the burn could only have been caused by the patient moving while the electrode was applied to her back.

An action was instituted against the doctor, claiming that she suffered a severe burn as a result of the doctor's negligence in absenting himself from the treatment room and permitting the patient to receive the treatment without the presence of either the doctor or a nurse. When the case came up for trial, the plaintiff's attorney stated to the judge that he had been unable to obtain medical testimony to support his case and requested an adjournment that he might secure such a witness. The trial of the case was adjourned, and when the case was again called for trial the plaintiff's attorney announced to the court that he had still been unable to obtain medical testimony, and at that time at the suggestion of the court consented to discontinue the action against the physician.

NEWS NOTES

FOURTH DISTRICT BRANCH

The Twenty-fifth Annual Meeting of the Fourth District Branch of the Medical Society of the State of New York was held on Wednesday and Thursday, October 21 and 22, 1931, at the Queensbury Hotel in Glens Falls, N. Y.

The meeting was called to order at two-forty P. M. by the President, Dr. Frank vander Bogart, of Schenectady, N. Y.

At this session the following papers were presented and thoroughly enjoyed by the large number of physicians present.

"Neurology in General Practice—The Early Diagnosis of Remediable Lesions," was given by Wilder Penfield, M.D., of Montreal.

"Gall Stones—A Study in Perspectives," was read by Edwin MacD. Stanton, M.D., of Schenectady, N. Y.

"Anthrax," Edward C. La Porte, M.D., of Amsterdam, N. Y.

"Certain Obstacles to the Development of the Language Function in Children," was presented by Samuel T. Orton, M.D., of New York City.

These papers were fully discussed by various members present.

In the evening a Dinner was given at the Hotel Queensbury to those in attendance by the Warren County Medical Society of the State of New York. Short talks were given by Dr. William D. Johnson, President of the Medical Society of the State of New York, and by Dr. T. P. Farmer, Chairman of the Committee on Public Health and Medical Education. The principal speaker of the evening was Mr. J. Thacher Sears of Glens Falls, who delighted his audience with his talk on "The Great War Path," describing the many locations of historical interest which so abound in this part of New York State.

The second session was called to order by Dr. vander Bogart at nine-fifty A. M., Thursday, October 22nd. At this session the following papers were presented:

"The State Orthopedic Program," by Walter J. Craig, M.D., of Albany, N. Y.

"Presentation of the Welfare Problem to the Board of Supervisors," by Raymond G. Perkins, M.D., of Malone, N. Y.

"The Lawyer and the Physician in Welfare Work," by John R. Parker, of Schenectady, N. Y.

"Medical Education," by Grant C. Madill, M.D., of Ogdensburg, N. Y.

These papers were fully and warmly discussed by many of the physicians present. At the close of the discussion the meeting adjourned.

This annual meeting was conspicuous in the large attendance of members from the different parts of the district, many of whom, because of the large area covered, had come long distances to be present.

SYLVESTER C. CLEMANS, M.D., *Secretary.*

HERKIMER COUNTY

The regular meeting of the Medical Society of the County of Herkimer was held at the Waverly Hotel, Herkimer, N. Y., Tuesday evening, October 13, 1931. Dr. H. C. Murray, President, called the meeting to order at 9 P.M. The following members were present: Doctors Murray, Brooks, Moore, Crofts, O'Neil, Love, Diss, Whittemore, Barnes, and Conterman. Two new physicians, having recently located in Herkimer, were present as invited guests, namely: Dr. Dominick Aloisio and Dr. W. J. MacDonald.

The minutes of the last meeting were read and approved. Discussion upon a motion that the President appoint a member to act as a reporter, brought out the fact that the by-laws of the Herkimer County Medical Society already provide for these functions through means of a Publicity Committee. The President then instructed the member of the committee then present to assume the duties of reporter.

A nominating committee was appointed by the President to make nominations for the various offices to be voted upon at the annual meeting of the Herkimer County Society to be held in December.

Dr. O. Houghton Love of Little Falls read an interesting paper on "Surgical Technique," emphasizing the value of teamwork between the surgeon and his assistants, attention to detail, avoidance of trauma, choice of anaesthetic, etc.

Dr. Howard C. Murray, President of the Society and delegate to the last State Medical Soci-

ety meeting, made a report of the State meeting and brought forth many interesting details and explanations of the business transacted there.

At the close of the meeting refreshments, consisting of sandwiches and coffee were served.

The program committee consists of Doctors T. B. O'Neil, O. H. Love and C. C. Whittemore.

FRANK B. COUNTERMAN, *Reporter.*

SCHOHARIE COUNTY

The seventy-fourth annual meeting of the Schoharie County Medical Society was held in Cobleskill, New York, on Tuesday, October 13, 1931, the business session in Hotel Augustan and the scientific session in the high school auditorium. The meeting was called to order by the President, Dr. Joseph F. Duell.

The possibility of a clinic on pediatrics being held in the county for our society was considered, and it was moved, seconded and carried that if possible, such clinic shall be held in Cobleskill on the first Thursday in December. Drs. D. W. Beard and J. F. Duell were appointed a committee to make arrangements.

On motion it was decided that all matters affecting the interest of our society and desirable for publication in the State Journal be given to the secretary to record and forward.

These officers were duly elected and committees appointed for our society for 1932:

President, Dr. Ward L. Oliver
Vice-President, Dr. Roy G. S. Dougall
Treasurer, Dr. Le Roy Becker
Secretary, Dr. Herbert L. Odell
Censor, Dr. Willard T. Rivenburgh
Delegate to State Society with power of substitution, Dr. David W. Beard
Legislative Committee, Drs. H. R. Bentley, L. R. Becker and C. L. Olendorf
Public Relations Committee, Drs. D. W. Beard, W. S. Pomeroy and L. R. Becker
Public Health Committee, Drs. D. W. Beard, W. S. Pomeroy and L. R. Becker
Publicity Committee, Drs. J. J. Beard, L. Driesbach and R. G. S. Dougall
Physical Therapy, Drs. M. Bruce, R. G. S. Dougall and D. W. Beard
Medical Economics Committee, Drs. Ward L. Oliver and David W. Beard

It was moved, seconded, and carried that Dr. Crampton's letter relative to medical broadcasting be referred to the Public Relations Committee.

Dr. Bentley, as Chairman of Legislative Committee, in his annual report, requested the members to express their opinion on certain measures that will probably be brought before the State Legislature this winter. On motion it was unanimously decided that Schoharie County Medical Society is opposed to any and all legislation that will lower the standard of the present Medical Practice Act.

On recommendation by the Comitia Minora, Dr. Duncan L. Best of Middleburg was elected to membmership.

Dr. George W. Augustin of Oneonta gave an especially entertaining paper on his "War Experiences as a Medical Officer."

Inaugurating a series of six post-graduate lectures on dermatology and syphilology, each to be given by a specialist on the second Tuesday of each month in Cobleskill High School at 2 P.M., Dr. Earl Dorland Osborne, chief dermatologist and syphilologist, City and Children's Hospitals. Buffalo, gave a masterly, illuminating, and deeply interesting paper on "Common Skin Diseases, Exclusive of Eczema," which was well illustrated with slides.

HERBERT L. ODELL, *Secretary.*

WASHINGTON COUNTY

The annual meeting of the Medical Society of the County of Washington was held at Hudson Falls, October 6, 1931, at 4.30 P. M., with 22 members and 6 visitors present.

The Treasurer reported $107.17 in the society's funds.

The President appointed Drs. Byrnes, Pashley, Sr., and MacDonald as a nominating Committee and the following officers were nominated and elected:

President, D. M. Vickers; Vice-President, D. E. MacArthur; Secretary, S. J. Banker; Treasurer, C. A. Prescott; Censors, A. E. Falkenbury, Samuel J. Pashley, Jr., and J. H. Ring.

Committee on Legislation: W. A. Leonard, Chairman

Committee on Public Relations and Medical Economics: M. A. Rogers, Chairman.

Committee on Physical Therapy: Samuel J. Pashley, Jr., Chairman.

The matter of the Governor's Special Health Commission as reported in the State Journal, was discussed and a motion passed that we call a

special meeting in the near future to consider our attitude toward this subject

Dr Munson presented the following resolution from the Board of Supervisors, which was approved

'In view of the fact that a number of cases of syphilis and gonorrhea are present in the county, and that difficulty is experienced in getting treatment, and that many of these cases have to be sent out of the county, it is resolved to call this to the attention of the Washington County Medical Society and request that the Medical Society may wish to designate certain physicians who may be willing to operate clinics in centers in Whitehall, Granville, Cambridge, and Hudson Falls"

A motion was made by Dr Byrnes and seconded by Dr Pashley, and carried that the President appoint a chairman of each district who shall call a meeting of the men in his community, and designate a man to carry on the county venereal work in his community Doctors Ring, Falkenbury, Leonard and Byrnes, were appointed local organizers

Dr B C Tillotson of Fort Edward, gave his presidential address on "Non-Epidemic Encephalitis,' mentioning the difficulties of diagnosis

Dr J T Park of Hudson Falls, presented a paper on "Therapeutic Fads and Fancies," mentioning the treatment of bedsores, hiccough, ringworm, whooping cough and pain of cancer

Dr James Vander Veer representing the State Society and Dr Albert Pfeiffer representing the State Department of Health discussed the reporting and control of venereal diseases

Dr A B Soule from the University of Vermont presented a paper on "Some Studies of the Renal Function"

S J BANKER, *Secretary*

A special meeting of the Washington Medical Society was held in Hudson Falls, on November 5, with 17 members present

The special committee on venereal disease treatment, reported that Dr Leonard had made arrangements with Drs Vicker and Fortune to treat cases at the Mary McClellan Hospital in Cambridge and that Dr Byrnes had appointed Dr C A Prescott of Hudson Falls

Dr J S Lawrence explained the preliminary report of the Governor's Health Commission, and Dr W A Leonard President of the State Sanitary Officers' Association discussed County Health Units The County Society voted to favor the principle of county health supervision, and to approve the resolutions adopted by the State Sanitary Officers' Association (See this JOURNAL July 15, page 909)

S J BANKER, *Secretary*

GENESEE COUNTY

A regular meeting of the Genesee County Medical Society was held on September 18, in the Blue Bird Inn, Batavia, with the president, Dr P J Di Natale, in the Chair and sixteen members present The subject of the evening was poliomyelitis and was led by Dr Loren B Manchester of Batavia, who has been appointed consultant in the disease by the State Department of Health The use of immune serum was urged and methods of the early detection of the disease were described

The session was closed with a dinner

FRANK R HALL, *Secretary*

The regular fall meeting of the Genesee County Medical Society was held on Monday, October 26, at 5 00 P M, at Batavia, New York

Officers for the ensuing year were elected as follows

President Dr G Henry Knoll LeRoy
Vice-President Dr Frank R Hall, Batavia
Secretary and Treasurer Dr P J DiNatale, Batavia
Delegate to the State Society Dr P J Di Natale, Batavia
Alternate to the State Society Dr I A Cole, Batavia

The Scientific Program consisted of a paper by Dr Clayton Greene of Buffalo, on "The Medical Man's Attitude on So called Acute Abdomen"

Twenty three members were present and three visitors Dr P J DiNatale, President, was the presiding officer

FRANK R HALL, *Secretary*

THE DAILY PRESS

Reg'lar Fellers — An Appetizer — By Gene Byrnes

From the *New York Herald Tribune*, September 18, 1931.

DIETING AS IT IS TOO OFTEN DONE

CONDITIONS FOR SUPPORTING LIFE

An editorial in the New York *Herald Tribune* of October 4 comments on remarks of Sir Halford Mackinder, President of the British Association for the Advancement of Science, who urged "that the remarkable accident of the earth having an ocean is the essential cause of those other cosmic accidents called life and man."

The editor comments:

"Astronomers frequently speculate about how many solar systems are to be expected in the universe of stars. The first necessary coincidence is that of near collision of two suns; for it was such a close approach, accepted theories run, that generated this solar system of ours. Stars are many but scattered. An orange on top of the Empire State Building, a second one at Bogota, Colombia, a third at the Azores, and others at equal distance in other directions would represent, it is computed, the average sizes and mutual distances of bright stars capable of creating planets. These oranges would move, to duplicate the average movement of the stars, about a half mile in a century. Calculate how long it would take for random motion of these oranges to cause collision between two of them and you have an idea of how often suns come near enough for planets to be formed.

"Small as is this chance, the stars are so many that no insignificant number of solar collisions probably has happened. Perhaps these have left behind them many planetary families; but, two more chances stand in the way, Sir Halford Mackinder pointed out, of the duplication of life. One is temperature. Any planet aspiring to duplicate the life record of the earth must be at just that distance from its sun which will provide a temperature between the narrow limits of freezing water and destruction of delicate materials like protoplasm. More than that, it is necessary for this aspiring planet to have a liquid ocean, a further accident which our earth probably owes to the detachment of a part of its original crust to form the moon. Had any link in this chain failed to be forged, Sir Halford suggested, life would have been impossible. Potentially, life may be implicit in all matter. Actually, it may be unique or almost so, if for no other reason than that other worlds have no oceans in which it could start."

NEW SOURCE OF RADIUM

A newly discovered source of radium is described in an editorial in the *New York Times* of October 31, as follows:

"The discovery of a deposit of radioactive pitchblende in the Great Bear region of Canada is an event of first-rate commercial and scientific importance. Czechoslovakia was once the world's largest producer of radium. It had to yield first place to the Chinkolobwe mine in the Belgian Congo. So rich is the African deposit that the Belgians have had a virtual monopoly of radium.

"The newly discovered Canadian ore yields from 3 to 4 grams of radium to the ton; the Congo deposits only a gram to every ten tons. The present price of $70,000 a gram ought to fall. Thousands of cancer patients will benefit if it does. The present world supply of radium is only 600 grams—less than three cupfuls."

AUTOMOBILE CONTROL

The New York Times of November 3 contains the following editorial note on the comparative ease of stopping an automobile going at various speeds and on various pavements

'At a recent meeting of the Society of Automotive Engineers one of the speakers produced a table which all automobile drivers should learn by heart Familiar enough to the expert, but possibly not to the layman, it deals with the distance and time it takes to stop a car going at different speeds and on different types of pavement

"A properly equipped car traveling at 20 miles an hour on a concrete road can be brought to a full stop in a few inches less than 15 feet But if it is traveling 40 miles an hour, it will require not twice as much room to stop, but four times as much, or 60 feet If it is traveling 60 miles an hour it will cover 135 feet of highway before it can be stopped

"The minute the car is tried out on other surfaces the 'coefficient of friction' diminishes and the required distances increase On firm gravel they are 27 feet 107 feet and 240 feet, respectively, for speeds of 20 40 and 60 miles an hour, the corresponding figures for 'wet creosoted wood block' are 133, 536 and 1,200

"This almost geometric progression affords one ready explanation of the observed close relation between high speeds and fatal accidents"

LABORATORY USE FOR MURDERERS

Cleopatra used slaves and condemned criminals as subjects for laboratory experiments with poisons, apparently with satisfactory results from her point of view, but the suggestion has been made by modern scientists to use those under sentence of death for experiments with life-saving procedures, as is indicated in the following editorial in the *New York Times* of October 28

"'My hand trembles when I think of passing from dogs to human beings,' wrote Pasteur to Dom Pedro, Emperor of Brazil, in describing his experiments with rabies in some unpublished correspondence unearthed by La Revue de l'Amerique Latine To make the transition easy and to lighten his own conscience, Pasteur suggested that a king or an emperor might authorize experimentation with criminals On the eve of his execution a condemned murderer was to choose between the scaffold and inoculation with a chance for life If the man lived, as Pasteur was sure he would, society would have to protect itself by keeping an eye on him for the rest of his days

"Although probably horrified by the proposal, Dom Pedro replied that death sentences were commuted in Brazil and that 'if the rabies vaccine has no incontestable effect, who would prefer a doubtful death to one which is almost certain? Even in the contrary case, who would consent to a possible if not a probable suicide?" The imperial refusal to treat condemned criminals as if they were dogs was softened by an invitation to visit Rio and develop there a yellow fever vaccine which could be used without grave risks"

NOISE ABATEMENT

What can be done to lessen city noises to an endurable softness is indicated in the following editorial in the *New York Sun* of September 29

"The Noise Abatement Commission, appointed nearly a year ago to study ways and means of minimizing a disadvantage shared by all large cities, in its first report records some specific accomplishments The I R T introduced the first noiseless subway turnstile in April, complete installation is now being carried out as rapidly as practicable The B M T is testing another type of silent turnstile Thus the cause of complaint standing fourteenth on the list of those received by the commission is on the way to being eliminated A conference on river and harbor noises in January brought some progress in this respect Changes in the Sanitary Code and in the city ordinances effected by the commission have virtually put an end to the loudspeaker nuisance in business neighborhoods and have helped to diminish the annoyance caused by thoughtless use of the radio in residential districts The Commission recommends first, that a noise squad from the Department of Health be assigned permanently to investigate complaints of unnecessary noise and to enforce pertinent regulations, and also, that an energetic educational campaign be launched to make the individual citizen conscious of what he must do to make the city a quieter place Louder than the lion's roar, by actual acoustical measurements, is the din of riveters, of steamship whistles and subway trains, only slightly less noisy the roar of elevated trains and the blare of loudspeakers and automobile horns If New York wishes to hear the lion's roar above the many-voiced city's babel there is a contribution to silence waiting to be made by nearly everybody"

BOOKS RECEIVED

Acknowledgment ot all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.

BEDSIDE INTERPRETATION OF LABORATORY FINDINGS. By MICHAEL G. WOHL, M.D. Octavo of 321 pages, illustrated. St. Louis, The C. V. Mosby Company, 1931. Cloth, $6.00.

EARLY THEORIES OF SEXUAL GENERATION. By F. J. COLE, D.Sc.Oxon., F.R.S. Octavo of 230 pages, illustrated. Oxford, Clarendon Press, 1930. Cloth, $6.00.

MRS. DOSE, The Doctor's Wife. By JOYCE DENNYS. 12mo of 154 pages, illustrated. New York, D. Appleton & Company, 1931. Boards, $1.50.

THE INBORN FACTORS IN DISEASE: An Essay. By ARCHIBALD E. GARROD, K.C.M.G., D.M. 12mo of 160 pages. Oxford, Clarendon Press, 1931. Cloth, $2.75.

DYNAMIC RETINOSCOPY. By MARGARET DOBSON. Octavo of 56 pages, illustrated. New York, Oxford University Press, 1931. Cloth, $2.50. (Oxford Medical Publications.)

THE DIAGNOSIS AND TREATMENT OF VENEREAL DISEASES IN GENERAL PRACTICE: The Routine Management of Syphilis and Gonorrhœa Employed in the St. Thomas' Hospital Venereal Diseases Department. By L. W. HARRISON, D S.O., M.B. Fourth edition. Octavo of 567 pages, illustrated. New York, Oxford University Press, 1931. (Oxford Medical Publications.)

A SURVEY OF THE MEDICAL FACILITIES OF THE CITY OF PHILADELPHIA: 1929 Being in Part a Digest of the "Philadelphia Hospital and Health Survey, 1929." By NATHAN SINAI, D.P.H., and ALDEN B. MILLS. Octavo of 298 pages. Chicago, The University of Chicago Press, [c.1931]. Paper, $1.50. (Publications of the Committee on the Costs of Medical Care: No. 9.)

THE "MUNICIPAL DOCTOR" SYSTEM IN RURAL SASKATCHEWAN. By C. RUFUS ROREM, Ph.D., C.P.A. Octavo of 84 pages. Chicago, The University of Chicago Press, [c.1931]. Paper, $1.00. (Publications of the Committee on the Costs of Medical Care: No. 11.)

A MANUAL OF CLINICAL LABORATORY METHODS. By CLYDE LOTTRIDGE CUMMER, Ph.B., M.D. Third edition. Octavo of 585 pages, illustrated. Philadelphia, Lea & Febiger, 1931. Cloth, $6.75.

SURGICAL CLINICS OF NORTH AMERICA. Vol. 11, No. 4. August, 1931. (Mayo Clinic Number). Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues). Cloth, $16.00 net; paper, $12.00 net.

GONORRHEA in the Male and Female. A book for Practitioners. By P. S. PELOUZE, M.D. Second edition. Octavo of 440 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1931. Cloth, $5.50.

A TEXT-BOOK OF GENERAL BACTERIOLOGY. By EDWIN O JORDAN, Ph.D. Tenth edition. Octavo of 819 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1931. Cloth, $6.00.

THE PRACTICE OF MEDICINE. By A. A. STEVENS, A.M., M.D. Third edition. Octavo of 1150 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1931. Cloth, $8.00.

DEMONSTRATIONS OF PHYSICAL SIGNS IN CLINICAL SURGERY. By HAMILTON BAILEY, F.R.C.S. Third edition. Octavo of 277 pages, illustrated. New York, William Wood and Company, 1931. Cloth, $6.50.

STUDIES IN THE PHOTO-ACTIVITY AND THERAPY OF THE TUNGSTEN-TITANIUM ARC. By J. BURDON-COOPER, M.D., B.S. and ARTHUR ROBERTS, T.D., F.R.C.S.E. Octavo of 85 pages, illustrated. New York, William Wood and Company, 1931. Cloth, $3.50.

THE CARDIAC CYCLE. By HARRINGTON SAINSBURY, O.B.E., M.D. Octavo of 79 pages, illustrated. New York, William Wood and Company, 1931. Cloth, $1.75.

AIDS TO SURGICAL ANATOMY. By RICHARD H. HUNTER, M.D., M.Ch. 16mo of 184 pages, illustrated. New York, William Wood and Company, 1931. Cloth, $1.50. (Students Aids Series).

AIDS TO MEDICAL TREATMENT. By J. T. LEWIS, M.D., B.Sc. and T. H. CROZIER, M.D., D.P.H. 16mo of 244 pages. New York, William Wood and Company, 1931. Cloth, $1.50. (Students Aids Series).

YELLOW FEVER: An Epidemiological and Historical Study of Its Place of Origin By HENRY ROSE CARTER, M.D. Edited by LAURA ARMISTEAD CARTER and WADE HAMPTON FROST. Octavo of 308 pages, illustrated. Baltimore, Williams & Wilkins Company, 1931. Cloth, $5.00.

ANNALS OF THE PICKETT-THOMSON RESEARCH LABORATORY. Vol. VII. The Pathogenic Streptococci: The Role of the Streptococci in Erysipelas Skin Diseases, and Measles. Quarto of 441 pages, illustrated. Baltimore, Williams & Wilkins Company, 1931. Paper $10.00.

THE MODERN THERAPEUTICS OF INTERNAL DISEASES. An Introduction to Medical Practice. By A. P. CAWADIAS, O.B.E., M.D. Octavo of 147 pages. New York, William Wood and Company, 1931. Cloth, $3.75.

SIMPLE LESSONS IN HUMAN ANATOMY. By B. C. H. HARVEY, M D. Octavo of 434 pages, illustrated. Chicago, American Medical Association [c.1931]. Cloth, $2.00.

INTERNATIONAL CLINICS. Edited by HENRY W. CATTELL, A.M., M.D. Forty-first Series, Volume III. Octavo of 326 pages, illustrated. Philadelphia and London, J. B Lippincott Company, 1931. Cloth, $3.00.

ASTHMA AND HAY FEVER IN THEORY AND PRACTICE. By ARTHUR F. COCA, M.D., MATTHEW WALZER, M.D., and AUGUST A. THOMMEN, M.D. Quarto of 851 pages, illustrated. Springfield, Charles C. Thomas, 1931. Cloth, $8.50.

APPROVED LABORATORY TECHNIC: Clinical, Pathological, Bacteriological, Serological, Biochemical, Histological. Prepared under the Auspices of the American Society of Clinical Pathologists by JOHN A. KOLMER, M.D., Dr.P.H., and FRED BOERNER, V.M.D. Assisted by C. ZENT GARBER, A.B., M.D. Octavo of 663 pages, illustrated. New York and London, D. Appleton and Company, 1931. Cloth, $7.50.

TABLES OF FOOD VALUES. By ALICE V. BRADLEY, B.S. Quarto of 128 pages. Peoria, Ill., The Manual Arts Press, [c.1931]. Cloth, $2.00.

BOOK REVIEWS

A System of Bacteriology in Relation to Medicine By Various Authors (Prepared under the direction of the Medical Research Council) Volume VIII Octavo of 390 pages, illustrated London, His Majesty's Stationery Office, 1931 Cloth, £8 8 0 a set, £1 1 0 each

This volume deals with the pathogenic fungi, actinomycosis, leptothricae, spirochetes of which there is an especially good account, rat bite fever, the leptospiroses, yaws and the normal bacterial flora of man

Under the heading of spirochetes, about 100 pages are devoted to an excellent discussion of syphilis This includes not only a full description of the treponema and its biology but also the pathology of syphilis, a most up to-date discussion of the Wassermann and various precipitation tests and notes on chemotherapy

There are several plates with beautiful illustrations of spirochetes E B Smith

Health on the Farm and in the Village A Review and Evaluation of the Cattaraugus County Health Demonstration with Special Reference to Its Lessons for Other Rural Areas By C-E A Winslow, Dr P H Octavo of 281 pages, illustrated New York, The Macmillan Company, 1931 Cloth, $1 00

In reviewing a book one must use internal and external evidence both The first impression that one has, *is that this book being sold for one dollar, the format* is excellent and it is beautifully illustrated, though the illustrations are without title and might as well be for any other demonstration as for this one

The writer, evidently employed to do the work in the very first sentence of his preface emphasizes the impartial character of the work, an outsider may wonder Evidently from these considerations, this is a piece of propaganda, and as one reads his impression is confirmed We find no evidence of this statement, so far as we observe, but obviously emphasis and inclusion of material is with reference to the impression that it may make

Our Government can run a colony more completely, according to its ideas, than its own self-governing structure and an outside organization, fully supplied with funds, can naturally carry on a health procedure better than elected officials dependent on the funds which they can secure from an electorate

We know, from outside knowledge that a very careful and earnest committee from the Medical Society of the State, after thorough investigation, agreed in criticism of the demonstration, and we know also that the chief medical critic in Cattaraugus County still represents the profession of his County in organized medical councils We are still of the opinion that, if outside organizations offered their assistance and money to and through the regular organized channel, rather than by domination of them, a demonstration would be more effective and the continued improvement of the public health would be greater than when the outside organizations make themselves *unnecessarily conspicuous* W D Ludlum

Fighting Disease with Drugs The Story of Pharmacy A Symposium Edited by John C Krantz Jr Octavo of 230 pages, illustrated Baltimore The Williams & Wilkins Company, 1931 Cloth $2 00

Many a layman is obsessed with the notion that drugs are poisons Even in our own ranks there are so called therapeutic nihilists This popular symposium on medicinal therapy should serve to enlighten those who wish to be educated The ancient and modern methods of therapy are compared The reader is taken on a travel trip to the various parts of the world, and is shown the various plant and animal sources of value to mankind He is also taken to the biological laboratories, to the mineral kingdom, to government laboratories, and is given a clear insight as to what is going on in the scientific world to fight disease Emanuel Krimsky

An Introduction to Gynecology By C Jeff Miller, M D Quarto of 327 pages, illustrated St Louis, The C V Mosby Company, 1931 Cloth, $5 00

The author a teacher of long experience, is convinced that the larger works on gynecology do not answer the need of the beginning student, for the reason, that he lacks the ability to use them selectively

This book is intended solely for the use of beginning students and it includes only the essentials of the subject Therapy is not considered in this volume, because the author believes that the treatment of patients is not the business of the junior student

All the facts that a junior student should know about gynecology are thoroughly covered in this volume which is illustrated with cuts taken from standard textbooks The book is divided into sixteen chapters, and covers the anatomy and physiology of the pelvic organs, as well as inflammatory conditions and new growths of these organs Other chapters are devoted to the glands of internal secretion, malpositions of the uterus, and to disorders of function

The book is clearly written, well illustrated and is an excellent textbook for the junior student W S S

New and Nonofficial Remedies, 1931, containing descriptions of the articles standing accepted by the Council on Pharmacy and Chemistry of the American Medical Association on Jan 1, 1931 Cloth Price, postpaid $1 50 Pp 481 + LVI Chicago American Medical Association, 1931

This volume is the annual publication of the Council on Pharmacy and Chemistry of the American Medical Association giving the latest authentic information concerning those of the newer medicinal preparations found worthy of the consideration and use of the medical profession Each year the Council scans the general articles under which the various preparations are classified and revises these to conform to the latest and best medical thought

A glance at the preface shows that a number of preparations have been omitted because they conflict with the rules that govern acceptance, because their distributors did not present evidence to demonstrate their continued acceptability or simply because the manufacturers have taken them off the market Important revisions have been made in a number of the general articles and in the descriptions of various preparations Among the new preparations that have been found by the Council during the past year to be eligible for admission to the book are Amytal and Pulvules Sodium Amytal, 3 grains barbituric acid derivatives for use preliminary to surgical anaesthesia, Thio-Bismol, quinine bismuth iodide sodium potassium bismuthyl tartrate and Tartro-Quinobine, bismuth compounds for use in the treatment of syphilis, Scillaren and Scillaren B preparations containing the squill glucosides, two new cod liver oil concentrates, Synephrine, a new vasoconstrictor, and synthetic thyroxine

'New and Nonofficial Remedies' should be in the hands of all who prescribe drugs The book contains information about the newer materia medica which can not be found in any other publication

OUR NEIGHBORS

STATE MEDICINE FOR MISSISSIPPI

The leading article in the October issue of the *New Orleans Medical and Surgical Journal* is the annual oration before the sixty-fourth annual session of the Mississippi State Medical Association on May 12, 1931, given by Dr. J. B. Bullitt of Chapel Hill, North Carolina. The speaker advocated State Medicine as the ideal system of medical service. He first enumerated three common defects of present-day physicians as follows:

"1. We specialize too much, too early, and too narrowly. None would decry the wonderful achievements of the specialties. They are choice grafts upon the parent medical tree, and they yield a luscious fruit; but they require careful selection and judicious pruning. They must not bear too early nor grow too rankly, and their number must be limited, lest they slay the life of the root that gives them sustenance.

"2. We hospitalize many patients needlessly. The facilities for diagnosis of obscure conditions and for treatment of many severe illnesses can be obtained better, or more cheaply, in hospitals than in most private homes; but only too often, in subjecting patients to hospital expense, we are consulting our own convenience rather than the needs of the case.

"3. There are some whose days of study cease early in their careers. They attend no medical meetings, they do not visit hospitals and clinics, their books are out of date, their journals are the advertising manuals of drug manufacturers. The cause may be indolence or indifference or poverty, but the results are the same."

Leading up to the remedy, Dr. Bullitt says:

"It is not our professional failures, however, that form the chief basis for the present discontent. The public is not stirred so much by our inefficiencies as by the high cost of illness, and we are less worried by our own imperfections than by our inadequate rewards.

"Certain items in our generally accepted social philosophy are directly applicable to our present medical problem: (1) each individual is entitled to fair remuneration for his labors, (2) community rights take precedence over those of any individual or class, (3) the sick, the weak and the needy are a proper charge upon the health, the strength and the wealth of their neighbors.

"Community interests and human sympathy alike demand that the healthy bear a part of the load of the sick, that the wealthy carry a part of the burden of the poor. How can this be done without offending that fine sense of independence that constitutes the most valued possession of a free people? Shall we attain the desired end through sickness insurance, or State Medicine, or some other form of socialistic effort?"

Coming more nearly to the point, the speaker referred to community action in disease prevention, as follows:

"In medicine our greatest achievements have been in prevention of disease. Most of this has been through a socialistic application of scientific knowledge. Individuals have pointed the way, but it is public organization that has banished yellow fever from our land, has halted the threatened spread of bubonic plague, has brought typhoid fever to the vanishing point over wide areas, and has accomplished countless other benefits of which we all approve.

"Is it necessary or is it expedient to apply this principle to curative medicine? Our individual interests as physicians must be subordinated to the real needs and welfare of the public. A partial application is of ancient and honored usage. Free hospitals were in existence two thousand years ago."

Dr. Bullitt discussed state medical service as the ideal solution, and said:

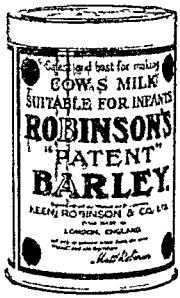
"In our ideal plan hospitals and laboratories, adequate to the needs and accessible to the people of each community, would be developed at public expense. Medical men, trained at public expense and maintained by public funds, would be distributed through these hospitals according to the needs of the population. Consultants and specialists, drawn from the more experienced and more skillful men, would be stationed at strategic points. Among this corps of specialists would be an adequate number charged with sanitary administration. Opportunities for graduate study would be afforded, and utilization of such opportunities would be required. Periodic examination for promotion and for continuance in the service would eliminate the unfit and indolent. Remuneration might be upon a fee basis, but probably salaries would be more practicable. The whole service would be free to the public. The organization and direction would be under the charge of medical men."

The objectors are discussed as follows:

"To the highly successful physician with a large and lucrative practice, the thought of a mere salary is naturally not appealing. The indolent doctor who has ceased study and whose practice depends upon his personality and upon

(*Continued on page* 1424—*Adv. xii*)

In vomiting cases as well . . .



As a modifier and diluent in the healthy infant's diet, Robinson's "Patent" Barley has been recognized as standard by the medical profession for over three generations

During that period, physicians have proved that Barley Water, containing a minimum amount of Starch, is invaluable in the treatment of abnormal cases as well, since it serves to insure easily digested, broken milk clots

In vomiting, for example—whether of habitual, or of pyloric origin—reports prove that very satisfactory results are achieved with Thick Cereal Feedings prepared from Robinson's "Patent" Barley The resulting mixture, when cooled, is a thick, jelly-like food of very smooth consistency

. . .

In adult dietaries, too—during pregnancy, in cases of intestinal and kidney diseases, and in post-operative feeding—Robinson's "Patent" Barley is used constantly with success

ROBINSON'S *PATENT* BARLEY *is prepared from the finest barley Quality is controlled through routine biochemical and bacteriological tests It is a uniform, clean product, free from irritating husks and bleaching agents*

Robinson's *"Patent"* Barley

Standard since 1823

(*Continued from page* 1422)

the medical ignorance of the public resents interference with his inactivity. Most of us are in neither of those classes, but we are borne down by the inertia of conservatism; we cling to our desire for independence, and we fear a lowering of our economic status. Probably it is because of these fears and prejudices that we are prone to believe that State Medicine would destroy research initiative and would lower professional standards."

The oration ends with a reference to doctors who work for salaries in research institutions, leaving the inference that all salaried physicians will continually put forth every effort to practice medicine according to the highest standards of science, ethics, and research.

DOCTOR GONE WRONG IN RHODE ISLAND

It is the policy of the NEW YORK STATE JOURNAL OF MEDICINE to avoid printing anything which reflects on the doctor either in sarcasm or in dereliction of duty. However, the following article from the October *Rhode Island Medical Journal* is quoted in order to illustrate the high moral standard of practising physicians generally:

"The complete confidence which the patient reposes in her physician is one of the most sacred trusts that the ethics of the profession zealously guards. Conversely, the violation of this confidence for one's personal gain is repugnant to any physician worthy of the name.

"Recently, there has come to light through press reports and court records, a second outrageous example of such deplorable conduct on the part of a doctor practising in this state under a license which must have been erroneously granted, considering the individual's education and training, and considering the subsequent abuse of licensure privilege which the man has apparently demonstrated.

"Now, it appears that taking advantage of a mentally incompetent patient, he has allowed her to transfer her property to him, presumably for 'safe keeping,' whether by fraudulent design or not will later appear. At any rate, the court-appointed conservator must sue to recover all of the items of a rather competent estate, while the doctor in question complacently 'allows' his erstwhile patient a mere pittance for her support. The whole transaction, if correctly reported, classifies that physician for the title of 'The Meanest Man,' and is in the same category as 'drunk rolling' and similar low forms of robbery of a defenseless person.

"The whole profession rises in protest of this regrettable business that stains the good name of the splendid body of medical men in this State who have always stood for decency, ethics, and above all fair play to a patient.

"Should the facts of the case eventually prove to be substantially correct, every respectable physician should call upon the State Commissioner of Health to revoke the license of the guilty party, and thereby purge the profession of a parasite.

"The profession, the hospitals and the public of Rhode Island must not permit a malignant growth to sap the life blood of the fair name of our State. A radical operation appears to be indicated."

OBLIGATION OF PHYSICIANS IN ARKANSAS

An editorial in the June number of the *Journal of the Arkansas Medical Society* enumerates some of the obligations of the medical profession in educating the public, and says:

"1. Every physician can do his part in this work in his daily visits and contacts with his patients. If this personal contact with patients is not carried out in an interesting, enthusiastic and educational manner, the physician is not fulfilling his professional obligations. There are many ways in which information concerning

(*Continued on page* 1425—*Adv. xiii*)

(*Continued from page 1424—Adv xii*)

medical facts may be given to the public that are certain to be helpful in establishing a more confident and intimate relationship between the public and the profession

"2 Public health and other medical societies should be one of the important obligations of the county society These lectures may be abstracted and published in the daily press Under the supervision of the secretary or other officer or committee of the medical society, all medical news at his command should be made available to the press The press has shown itself willing and anxious to publish this information and to cooperate with the profession in every way

"3 The radio as a means of disseminating medical news and information in which the public is interested, and about which it should know is being employed extensively, and undoubtedly it will be used more Properly regulated and controlled by medical societies and their officers, this plan of giving out medical facts is certain to lead to results of great value Those who control the radio corporations are overwhelmed with applications for time on their programs to broadcast quack remedies and cures and they are anxious to know what should be accepted and what should not It is one of the obligations of the medical profession to give them this information

"4 The consensus among members of the medical profession generally is that some sort of publicity should be supplied by which the public will be made to understand the nature, the purposes and the results of the efforts made by scientific medicine for prevention and control of disease The profession of medicine is under obligation to protect the public from unsound programs as much as to see that it is informed on the proper principles A committee on public relations composed of members who have made studies of these problems and who appreciate the obligations of the profession to the public, is a valuable part of a State organization

"5 The organization of all medical activities in each State so that the public health association State medical association, and all other associations and auxiliaries are under the one head helps greatly to coordinate all medical activities This scheme brings the medical profession as a whole into the leadership of all activities pertaining to medicine within the State It is not only the privilege of the profession to assume this leadership, but it is also its solemn obligation to direct all medical activities

"An organization that is responsible for the health and lives of so many individuals each year and that is economically responsible for the expenditure of so much time, energy and money, has a large responsibility and obligation"

DIGITALIS ASSAY

—PROMOTING A MORE ACCURATE METHOD OF STANDARDIZATION
—ADOPTION OF THE INTERNATIONAL STANDARD OF POTENCY

IN 1928 the following recommendation was made by the Frankfurt Conference "That when the dosage of digitalis or its preparations is expressed in units of activity, the unit employed for any preparation *and in any country* should be an international unit, which should be defined as the specific activity contained in 0 1 gramme of the International Standard Powder '

A powder equal in strength to the International Digitalis Powder has been used as an official national standard in Germany since 1928

Since that time recommendation has been made to adopt the International Standard in both the French Codex and the British Pharmacopeia

Upsher Smith, pioneers in the improvement of digitalis production and standardization, have already adopted the International Unit, because it provides the clinician with greater protection by furnishing a more accurate method of assay

With the adoption of the International Unit we put one International Unit of digitalis in one cc of the tincture and in one capsule or tablet. Note how this simplifies dosage, thus

1 International Unit = 2 grains U S P Digitalis Powder

1 cc Tincture = 2 grains U S P Digitalis Powder

1 International Unit Capsule = 2 grains U S P Digitalis Powder

½ International Unit Tablet = 1 grain U S P Digitalis Powder

Full information on the International Unit is supplied in our new booklet "New Thoughts on Digitalis Action and Dosage"

ADVERTISING IN WEST VIRGINIA

A report on advertising was accepted by the West Virginia State Medical Association on May 18, 1931, and appears in the *West Virginia Medical Journal* of November. Extracts read as follows:

"Advertising by medical societies, whether it be national, county or state, is one thing; advertising by the individual is another. Whether the association should or should not advertise is a question of policy, not a question of principle, and equally good men no doubt stand on either side. Not so the question of individual advertising—this is a question of ethics, of principle, not policy, and deserves our condemnation.

"W. A. Shumaker, editor of *Law Notes,* has well said: 'What makes a profession? If there is such a thing as a profession as a concept distinct from a vocation, it must consist in the ideals which its members maintain, the dignity of character which they bring to the performance of their duties, and the austerity of the self-imposed ethical standards. To constitute a true profession there must be ethical traditions so potent as to bring into conformity members whose personal standards of conduct are at a lower level, and to have an elevating ennobling effect on those members.'

"Paid newspaper advertising is so obviously improper that it rarely occurs among physicians; there is, however, an insidious form of indirect advertising that shows itself in the news and personal-interest stories and by getting medical papers (inadvertently?) into the hands of laymen. Ofttimes the offending doctor makes himself ridiculous by pretending annoyance and failure to understand how 'the news got out.' This makes us all wonder how the newspaper man acquired such intimate knowledge of medical subjects. Our Principles of Medical Ethics declare that the furnishing or inspiring newspaper or magazine comments concerning cases in which the physician has been or is concerned, and all other like self-laudations, defy the traditions and lower the tone of any profession and so are intolerable.

"The assumption that any group of men associated together for the purpose of operating a clinic or hospital have any ethical rights denied the individual physician is entirely erroneous. The Principles of Medical Ethics specifically provides that no institution or group by whatever name called is permitted any more latitude in the matter of advertising than is permitted to the individual physician. The reasons for this are certainly obvious and convincing.

"The physician we meet in everyday life is frequently heard to complain that he is denied things which seem to be all right in those of more exalted standing. With the justness of this com-

(*Continued on page* 1427—*Adv. xv*)

(*Continued from page 1426— Adv xiv*)

plaint we fully agree, and we affirm that neither years, honors, nor knowledge confer upon their possessors any ethical rights or privileges not held at the moment of graduation

"Generally speaking, our association members are to be commended for upholding the ideals of our noble profession We have less to regret than some other parts of our country

"Now we shall step from the obvious to the debatable What shall we do as an organized body? Every reader of magazines and the daily press must have observed the almost universal health appeal that has been incorporated into modern advertising Farfetched, irrelevant and illogical as some of these advertising illusions to health may be, they indicate that manufacturers, merchants and tradespeople recognize the present trend in health education and are attempting to correlate commercial and health values

Many of superior knowledge possessing both money and education, are unable to choose between yeast, electric horse-collars jiggle belts, synthetic sunshine, and the source of sound medical advice—the physician Others are unable to choose between a doctor of medicine and the cultist, quack or charlatan, while more lack the ability to choose the best qualified physicians Without honest dependable direction from the medical profession, who of the general public can know how to get thin, gain weight, prevent headache and sleeplessness and preserve sight, hearing, and general muscular tone?

"Should our Association determine upon any publicity measures, we think they should be especially directed towards preventive medicine and periodical health examinations"

ANNUAL REGISTRATION IN TEXAS

The September *Texas State Journal of Medicine* has the following comment on its new law similar to that of New York State, requiring the annual registration of physicians

"The annual registration law requires that each physician licensed to practice medicine in Texas shall register each year and pay a fee of $2 00 for the privilege This law becomes effective January first Physicians are allowed sixty days in which to pay the fee It is highly desirable that the State Board of Medical Examiners shall be in a position to take up its work of enforcing the Medical Practice Act promptly on the first of January Indeed, good work is being done now, but financial support is rather inadequate and uncertain It is anticipated that activities will be more than doubled on the first of January if the funds are in hand with which to pay the cost

The big idea now is to secure an accurate list of the practicing physicians of Texas, white or black, legal or illegal, regular or irregular."

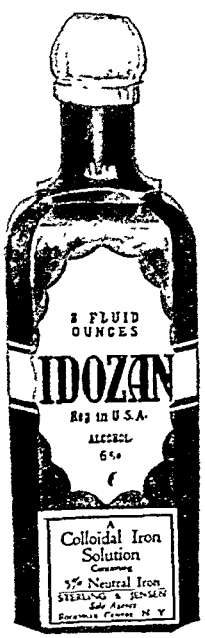
(*Continued from page 1427—Adv. xv*)

The State Board of Medical Examiners makes the following request of the doctors:

"County medical societies have been requested to furnish the secretary of the State Board of Medical Examiners, Dr. T. J. Crowe, Mercantile Building, Dallas, with the names and addresses of all who are practicing medicine within their several jurisdictions, including those who are believed to be practicing legally, and those who are believed to be practicing illegally, white or black, of whatsoever school or cult. There is no list of the sort available. The Directory of the American Medical Association contains a list of the practitioners of Texas who are legally qualified to practice medicine, as of the time the information was obtained, which may be a year or so out of date. In Texas, where there is more or less constant change of location of doctors, that is a matter of importance. It is believed that there are many reputable and ethical physicians in the state, who have never qualified legally for the practice of medicine, and who can easily and should at once, qualify. The names of these are not included in any list, and we should have them on record. Certainly no list of practicing physicians includes chiropractors, for one group. The State Board of Medical Examiners wants to know about them. Every little bit helps. The report of even one name will be gladly received."

PAYMENT FOR SERVICES IN OHIO

A just grievance of the medical profession is that a physician is called to treat a case by a municipality or other organization, which afterward refuses payment on the ground that the obligation rests upon another party. Doctors feel that the responsibility to pay for medical services is as great as that of providing medical services to those who are otherwise unable to obtain it; and this opinion was upheld by the attorney general of the State of Ohio quoted in the September number of the *Ohio State Medical Journal*, as follows:



"An opinion (No. 3,325) interpreting the statutes relative to payment by a township of medical services rendered the indigent was handed down by the attorney general, in reply to a letter from a county prosecutor, in which the following facts were set forth:

"One of the townships of the county has a contract with a physician to take care of the indigent sick. A person moved from this township into an adjoining township, and some miles further from the center of the first township. While living in the second township, he became ill and the trustees of the second township called upon the physician who was under the contract with the first township to treat this person. They intended

(*Continued from page 1428—Adv xvi*)

to pay the physician from their own township funds, but upon investigation found that he was still a legal charge upon the first township, and notified the first township, within the statutory time, of the services rendered

"Subsequently, the question arose Does the second township pay the bill to the physician, and the first township reimburse the second township? or is this to be regarded as part of the contract of the physician?

"Mr Bettman, in his opinion, held that under Section 3480-1, General Code, medical services requested by the trustees of a township for an indigent person whose legal settlement is in another township, should be paid by the township requesting such medical services, and charged to the township of legal settlement

"Moreover, in the following statement he specifically held that the physician under contract was entitled to compensation not specified in his contract for rendering services in another township under these conditions

"'The mere coincidence that the township authorized to request medical services chanced to call the doctor under contract with the township to which the patient was a legal charge does not in my opinion, act as a bar to prevent the doctor from receiving compensation for his services, rendered at the request of the second township, from such township' "

REPORTS OF MEDICAL MEETINGS IN INDIANA

The September number of the Journal of the Indiana State Medical Association contains the report of the Bureau of Publicity, which includes the following descriptions of its routine reports to the American Medical Association

In accordance with a request received from Dr C P Fordyce former news editor of *The Journal of the American Medical Association,* asking that programs of important medical meetings giving names of speakers, exact titles for their papers and talks, etc, be sent to the American Medical Association, the Bureau of Publicity adopted a form for making reports of medical meetings So diligent have been the county society secretaries in using these forms and so successful has this method of reporting meetings proved to be that the American Medical Association has asked that each State Secretary adopt a similar form for reporting meetings to

THE DOCTOR
THE NURSE
THE PATIENT

NO ONE is immune to perspiration and the discomforts and social implication that go with it, for perspiration often leaves in its wake an odor quite unpleasant.

Here is an opportunity for cooperation between the doctor, who prescribes the remedy, the nurse, who applies it, and the patient who may need it. The remedy is simple enough and safe.

NONSPI

(AN ANTISEPTIC LIQUID)

checks the perspiration and prevents the odor, too. It needs to be applied only once or twice a week under the arms and to those parts of the body not exposed to adequate ventilation. Trial supply gladly sent to physicians.

YES, I'd like to try NONSPI. Please send me a free trial supply.

the American Medical Association. This form, which is simple to the extreme, follows:

"REPORT OF MEDICAL MEETING"

"Name of Organization .....
"Place .....
"Date and time .....
"Speaker .....
"Title of paper .....
"Special features and comments:.....
.....
.....

"This blank is to be made out immediately following meeting and mailed to Thomas A. Hendricks, Executive Secretary, 804 Hume-Mansur Building, Indianapolis, Ind.

"Copies of the above form are distributed from time to time to the county society secretaries, who fill them out after each meeting and return them to headquarters office. Upon being received at headquarters office two copies are made of these reports, one being sent to the editor of *The Journal of the American Medical Association* and the other to the editor of the Journal of the Indiana State Medical Association. The original copy is kept on file at this office and is a constantly growing reference list to which any one may apply for information in regard to speakers and subjects for county society and district meetings. The secretaries and officers of county and district medical societies are urged to fill out these forms for each meeting and return them to headquarters office as soon as possible."

The expenses of the Bureau were as follows:

"Clipping service	$63.50
"Postage	191.70
"Stationery and mimeograph supplies	165.42
"Printing	8.80
"Traveling expenses of speakers	86.86
"Miscellaneous	78.90
"Total expense	$595.18"

ADVERTISING THE DOCTOR IN MINNESOTA

The October number of *Minnesota Medicine* contains the following editorial on advertising schemes to increase the doctor's practice:

"We are confronted from time to time with propositions conceived by some individual with an eye to business purporting to increase our field of professional usefulness. Most of us have the laudable desire to increase our clientele but we occasionally have a way of jumping at some tempting bait without careful investigation.

(*Continued on page* 1431—*Adv. xix*)

(*Continued from page* 1430— *Advertising*)

"A newspaper man conceives the idea that the local medical profession should receive more publicity, and works up the idea of a Sunday supplement array of photographs with an accompanying write up of the leading members of the local profession—for a consideration

'Or someone gets out a bulletin and to help defray expenses, seeks permission over the telephone to include your name—at a nominal charge

Or a persuasive individual shows you a copy of a directory of experts in the legal and medical profession which has been published for forty or fifty years You glance it over and sure enough it contains a very select list of the outstanding men in your locality and elsewhere You are secretly flattered

'Or some layman is getting up something new and different—a directory of reliable physicians all over the country Only those free from commercial taint and recognized by the profession itself are to be included Data given will be so complete that section of a physician for reference of patients will be easy How much demand for such a publication there will be however, is a matter of speculation

"A limited directory appears in a number of the state medical journals Paid insertions resembling professional cards with name, specialty and address appear monthly in the advertising section This practice falls into the category of local custom and cannot be criticized We can see some convenience in the method but most physicians are well acquainted with the profession of the state, and state journals have as a rule a limited circulation outside of the state We imagine few physicians would refer patients on the basis of state journal insertions Incidentally the practice furnishes an added source of income to the state journal and might be considered by our Association

The newspaper publicity mentioned is, after all, direct advertisement Directory insertions, while not strictly unethical, are probably of little value as a means of increasing one's practice"

FAITH HEALING IN TEXAS

The Texas State Journal of Medicine of October prints a letter from a leader of "a group composed of small but militant congregations which appear to be organized primarily for healing purposes and the emolument resulting there-

"'Done at.....Texas This 14 th day of Aug. A.D. 1931'"

This correspondence led the editor to comment on the recent action of the national convention of the Episcopal Church assembled in Denver during the summer. This convention affirmed the spiritual value of prayer for the sick, but also recognized the necessity of the physical ministrations of physicians. The editor comments as follows:

"The commission pointed out in its report that while the church must teach spiritual healing, because it is a part of the Gospel of Christ, it must not teach or use any method tending to lead people to believe that it is the only, or even primary, purpose of the Gospel. Scientific medicine is given credit for what it has done for humanity in the alleviation of suffering caused by disease and accident, and in the elimination and eradication of contagious diseases. It is

(*Continued on page* 1433—*Adv. xxi*)

The recipe was good and the cook was not to blame

But the stomach, heedless of the parable of Marcus Aurelius toward cooperation, rebelled. The result was an excessive acidity that did the stomach no good and upset the whole man. The stomach has a way of its own in illness and health. Gastric hyperacidity often results when there is hardly any good reason for it. But CAL-BIS-MA promptly corrects excess acidity and keeps it corrected. Sodium and magnesium for quick neutralization; calcium and bismuth for prolonged effect, colloidal kaolin for adsorbing gases and toxic substances. No excessive gas formation to exchange one discomfort for another. No digestive ferments for make-believe. And that is in which Cal-Bis-Ma is different.

In Gastric Hyperacidity

CAL-BIS-MA

TRY IT AND BE CONVINCED. A SUPPLY IS YOURS FOR THE ASKING

WILLIAM R. WARNER & COMPANY, Inc., 113 West 18th Street, New York City

(*Continued from page 1432—Adv vi*)

stated that while this service has been incidental to the 'illumination of the spirit of God, the church will not fail to give due credit to the medical profession for its noble work for poor suffering humanity.' Stress should be placed on health rather than healing, and the 'sacrament of unction' has both psychological and sacramental value, according to the report. 'It is clearly scriptural, and has behind it the authority of apostolic times. We rejoice that there is a form of service for its administration. But no one, however high the value he placed on it would question that it is only a means to a spiritual end. A sane, constructive health movement, cannot be based on the use of consecrated oil. That is not its primary truth. The same may be said of "a gift of healing," so much disputed and about which we know practically nothing. No movement could be based on that.'

"There is no apparent reason why spiritual healing and material healing should not go hand in hand. If there is a reason why it may not be so, it is because of the insistence of the faith healer that his prayers and the faith of the patient will remove disease of whatsoever character and cure the patient without reference to material means. There is a growing tendency among thoughtful, educated people, interested in both religion and science, to draw the two together and make them complimentary of each other, quite in contrast to the but recently generally held idea that the two are antagonistic, at least, that they do not comport, one with the other. We believe we see in the instance above referred to a definite step in this direction, and we cannot help but feel that it is a hopeful sign, and it will be agreed, we are sure that we are sadly in need of hopeful signs just now."

BUDGET OF NEBRASKA STATE ASSOCIATION

The July number of the *Nebraska State Medical Journal* contains the following budget adopted by the Council of the Society —

"The following budget was recommended by the Council for the year 1932

Cocomalt for...

CONVALESCENTS—The high caloric value and quick assimilability of Cocomalt makes it an especially valuable food for convalescents

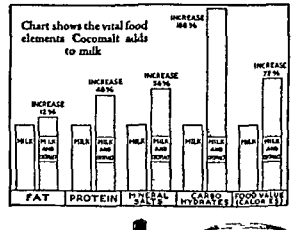
GENERAL DEBILITY—The necessity for a concentrated food of high digestibility in asthenic conditions is met by Cocomalt.

MALNUTRITION—Undernourished children and adults respond splendidly to the balanced ration of Cocomalt mixed with milk. Furthermore, it increases the appetite

TUBERCULOSIS—Cocomalt is very useful in increasing the caloric value of tubercular diets without throwing an additional strain upon the digestive system. Its mineral content is likewise useful in producing calcification of tubercular lesions

POST OPERATIVE—Following an operation, Cocomalt meets the demand for a highly nutritious food that does not produce intestinal fermentation or stasis

FEVER CASES—The high carbohydrate content and caloric value of Cocomalt make it extremely valuable in treating fever cases. It saves body proteins



EXPECTANT MOTHERS—During pregnancy, Cocomalt answers the great need for Vitamin D and helps provide the additional food needed by the developing foetus

NURSING MOTHERS—Cocomalt provides necessary food elements for the production of milk, without inducing constipation

Cocomalt—the delicious food drink—adds 70% to the caloric value of milk.

RURAL DOCTORS IN WEST VIRGINIA

The October number of the *West Virginia Medical Journal* contains the following editorial on rural doctors in the State:

"In a recent editorial, the *Wheeling Intelligencer* deplored the present-day scarcity of country doctors in West Virginia. The editorial pointed out that the old generation of country doctors was fast disappearing and that some system should be worked out whereby the people in rural districts could receive adequate medical attention. As a remedy, the *Intelligencer* suggested that communities should be allowed to send one of their own boys to medical college, and that the student, after completing a part of the required course, should then be allowed to practice in his own community.

"There are several fallacies in the *Intelligencer* editorial. In the first place, country doctors are not dying out. In 1929 a bill was introduced in the West Virgina Legislature to accomplish exactly what is outlined in the newspaper editorial. The sponsor of the bill, speaking in its behalf, stated that in two years' time the number of country doctors had dwindled from 67 to 59. No one thought of doubting the statement until a representative of the West Virginia State Medical Association compiled a complete list of every country doctor in the State, with their names, ages, and addresses. There were more than 500 names on that list, and the list is larger today than it was in 1929. The residents in the rural sections of West Virginia have available and are receiving better medical attention today than at any other time in the history of this State.

"In spite of the great improvement in rural medical service during the past decade, we realize, of course, that it is not nearly as satisfactory as the medical service obtainable in a city. But that is a question of economics and not of philosophy. By the same token, the country stores are not as satisfactory as the city stores. The schools are not as good. The automobile mechanics are generally not as skillful. You can't put a complete line of merchandise in a crossroads store because the store would go bankrupt. Also, you can't put a complete line of specialists in a village because they can't make a living.

"The very idea of turning a second- or third-year medical student loose on our good people in the rural areas is atrocious. Our country brothers are too good for that sort of punishment. They should not be urged or coerced into accepting a substitute when they can get (though often difficult) the real thing. There is no substitute for the standards of medical practice. A patient either gets the real thing or he gets nothing at all. We hope that the day will never come when our rural residents are forced to depend upon medical service from a synthetic doctor.

"It is stated that the older generation of country doctors is dying out. That's true. But in their stead a new generation, fresh from the medical colleges of America, is coming on. Almost daily we hear the statement that the young doctors, just out of college, all rush to the larger centers of population and turn up their noses at country practice. This statement, though fashionable, is one of the many lay myths that come from the nowhere into the here. It is true that most doctors eventually wind up with a city practice. But few of them, especially in West Virginia, attempt to jump from interneship to urban practice. The vast majority carry their newly acquired knowledge to some rural section or small town where the cost of living is not too high and where they can practice in contentment and safety for five or ten years before tackling the more glamorous allurements of the city. When their nest-egg is of sufficient size, then, and then only, will they begin to look for a larger world to conquer."

VOL. 31, NO. 23 NEW YORK, N. Y. DECEMBER 1, 1931

THE INTERPRETATION OF BLADDER SYMPTOMS

By VINCENT VERMOOTEN, M.D., New Haven, Conn.

From the Department of Surgery, Yale University, New Haven, Conn. Read before the Delaware County Medical Society at Delhi, N. Y., June 11, 1929.

IN order to understand and correctly interpret urinary symptoms one must be thoroughly conversant with the normal mechanism of urination. This can be studied through the cystoscope, as Young did many years ago and is more fully elucidated by a knowledge of Wesson's experimental work on the anatomy of the bladder trigone and sphincters.

Anatomy

The bladder consists of a main mass of muscle, the detrusor vesicae (which is with much difficulty separated into an inner circular and an outer longitudinal layer) a second sheet of muscle known as the trigone as well as two sphincters, an internal and an external, either of which can prevent incontinence.

The trigone anatomically is derived from the muscle layers surrounding the lower ends of the Wolffian ducts and lies as a separate layer on the floor of the bladder. It takes origin from the lower ends of the ureters, arches over the internal sphincter (under the mucosa) forming the "uvula vesicae" and is inserted in the posterior urethra in the region of the verumontanum.

The detrusor vesicae is supplied by both the true sympathetic nervous system from the third and fourth, sometimes also the first, second and fifth lumbar segments, via the hypogastric nerves to the vesical plexus, and by the autonomic or parasympathetic system from the first second and third sacral segments. These latter leave the sacral plexus by the nervus erigens which also contains peripheral sensory fibres from the bladder.

The trigone is supplied only by the true sympathetic, while the external sphincter is supplied by the pudic nerve which derives its peripheral and autonomic fibres from the sacral plexus.

The spinal centers that maintain the tone of these muscles are in the neighborhood of the fifth lumbar segment.

Physiology

Young and Wesson found that the emptying of the bladder was not, as formerly had been supposed, merely a contraction of the detrusor vesicae with a relaxation of the sphincter by its inhibition. On the contrary, the trigone being arched over the internal sphincter (which is normally in a state of tonic contraction) and being fixed at its insertion and origin when it contracts must shorten and in so doing, open the internal sphincter.

When the normal bladder contains urine, a rhythmical contraction is set up which increases in force and frequency as the bladder continues to fill. Soon the trigone also contracts slightly and may allow one or two drops of urine to enter the posterior urethra. This communicates itself to the brain as a desire to void. As the contractions become more violent the messages become more urgent until eventually the act of urination is accomplished.

The sensation of the desire to void depends on the intravesical pressure and not upon the volume of fluid in the bladder. The threshold of pressure of course, depends on the degree of irritability present.

Now the bladder, unless there is some systemic disease such as diabetes mellitus or insipidus or chronic nephritis or some nerve lesion which would impair its normal functioning, should require emptying only three to five times a day (depending on the patient's fluid intake) and not at all at night. In the absence of these lesions one should not ascribe the increased frequency merely to habit, age, hyperacidity or some similar condition.

The Bladder Capacity

The normal male bladder has a capacity of about 350 c.c. and the female about 500 c.c. Both may hold half as much again and still be normal but they should not hold much less. Accordingly, as our average output is 12-1500 c.c. a day a normal bladder will empty only 3.5 times. If there is any underlying pathologic change which will diminish the bladder capacity one can readily see that the patient would void more frequently. Any

extensive ulcerative process, such as tuberculosis, which infiltrates the bladder musculature and so diminishes the amount of urine it can hold, will of necessity cause frequency of urination. Interstitial cystitis which is an inflammatory process affecting the submucosa of the bladder, similarly diminishes its capacity, although in this instance it is a voluntary diminution, for the bladder can readily be distended under some form of anaesthesia. Due to the inflammatory reaction being in the submucous layer, distention of the bladder causes the mucosa over the diseased area to crack and bleed. This causes pain, consequently the patient empties his bladder just before this point is reached and as a result voids small quantities frequently.

Residual Urine

When the bladder is not able to empty itself completely, the amount remaining is known as the residual urine. Whether this be due to a benign or malignant enlargement of the prostate, a contraction of the vesical orifice, urethral stricture, diverticulum of the bladder, cystocele, myoma pressing on the urethra or to any other cause, the frequency of urination increases with the quantity of the residual, provided the capacity remains the same. This is readily understood if one realizes that the bladder, not being able to empty itself completely, requires a smaller amount of additional urine to reach the necessary threshold of intravesical pressure which will give the patient the desire to void.

Frequency

Frequency of urination apart from being due to a diminished bladder capacity (the result of the presence of residual urine or some other pathologic lesion) very commonly occurs in patients who have a normal or even an increased bladder capacity. This is due, not to over distention, but to an irritation or stimulation of either the trigone or posterior urethra. This is the type of frequency which is concomitant with infection, and as this is present in about 60% of urinary tract lesions, one can see how great a part trigonal or posterior urethral irritation plays in the production of the bladder symptoms. For this reason, probably, frequency of urination is the most common of all urinary symptoms. It is often the first and not uncommonly the only symptom which the benign enlargement of the prostate gives and is practically pathognomonic of the onset of a posterior urethritis in a gonorrheic who is being treated for an acute anterior lesion.

Pain

Pain is not a very common symptom of the lower urinary tract. We have the pain of the over distended bladder, which in reality is more an intense desire to urinate, together with a sensation of fullness and discomfort. Real acute pain is experienced in cases of elusive ulcer (interstitial cystitis) if the bladder is allowed to become too full; after urinating a dull ache remains present for half an hour or more. Rupture of the bladder may also be associated with very severe pain. Extensive bladder ulceration and large bladder tumors may cause a dull ache suprapubically. Foreign bodies (including stones) when accompanied by infection are most commonly responsible for stranjury and tenesmus causing intense discomfort in that way. Pain at the end of the penis indicates, as a rule, a lesion of the posterior urethra. Burning and smarting on urination is of course evidence of lower urinary tract infection, the inflamed urethra being generally responsible for these symptoms.

Urgency

Urgency, the hurried call to urinate, is the result of rather strong stimulation of the trigone. It practically always indicates an acute inflammatory process in the bladder which has involved the trigone, an ulceration of the trigone or posterior urethra or an acute posterior urethritis (either primary or secondary to an acute prostatitis) consequently it is almost always associated with frequency.

Hesitancy

Hesitancy, in the young, is most commonly the result of nervous inhibition. In the middle aged, it is more commonly the result of a strictured urethra but is then associated with a small stream, good trajectory and frequently with spraying. It is, however, a far more common symptom in elderly men and is then due to difficulty of the trigonal muscle to open the internal sphincter due to certain pathologic changes. These take the form of benign adenomata of the prostate which put the action of the trigone at a great mechanical disadvantage; or of infiltration of the internal sphincter or trigone or both with carcinoma; or, as in the case of contracture of the vesical orifice, with scar tissue. In the female, cystoceles, myomata, prolapsus uteri and other gynecologic lesions may mechanically interfere in the same way.

Acute Retention

Acute retention of urine, is, in the young, a relatively uncommon finding, although most urologists see at least one or two cases a year which are due as a rule to congenital lesions of one kind or another. The most common are stricture of the anterior urethra, congenital valves of the posterior urethra or diverticula of the bladder. In early adult life infections play the great part and take the form of acute prostatitis, or stricture of the urethra. Cord lesions occur later with resultant bladder paralyses causing acute retention, paradoxical incontinence or automatic bladders. Syphilis is the most common offender here, then

spina bifida, cord tumors, primary anemia and arteriosclerosis, not to mention trauma infections and metastatic lesions to the spine In women cystoceles, prolapsus uteri or myomata on the anterior surface of the uterus pressing on the urethra or distorting the bladder frequently are responsible for retention at this age In elderly men the benign and malignant enlargements of the prostate, contracture of the vesical orifice, median bars or acquired diverticula account for the onset of this condition Here the trigone, which is already markedly hypertrophied from overwork, is no longer able to open the internal orifice satisfactorily particularly in the presence of the œdema which occurs in an acute cystitis or the congestion of the vesical neck which results from a long automobile ride exposure etc

Incontinence

True incontinence, the condition in which urine constantly leaks from the bladder, is rare except as the result of trauma (operative or otherwise) for it requires the paralysis of both the sphincters which guard the outflow of urine from the bladder In women, in whom there is so little tissue between the bladder and vagina incontinence from vesico-vaginal fistulae occur not uncommonly; these, however, can be closed without much difficulty if operated on transvesically

Enuresis is frequently looked upon as nocturnal incontinence although it is not a true incontinence. Very frequently it is due to habit, occasionally to irritative lesions in the form of a redundant prepuce, a phimosis or a stricture of the external urethral meatus (the end result of a meatal sore) At times in persistent enuresis over many years, when all other causes have been ruled out, we find on cystoscopic examination valves of the posterior urethra or other congenital lesions

Hematuria

Hematuria is not a urinary symptom but to the patient at least it is an alarming and very positive finding and to the physician it should be a warning of disease which demands his immediate attention and respect, for it indicates a very definite pathological state the nature of which should be and in every case (with a rare exception) can be, determined

Hematuria may be terminal or total, that is one may pass a few drops of blood just at the end of urination or the entire urination may be bloody An ulcerative lesion in the posterior urethra, a vesical calculus when accompanied by straniury and at times a bladder tumor may occasion blood in the last few drops of urine passed In total hematuria the bleeding may find its source either in the bladder, ureters or kidneys This can, as a rule readily be determined during cystoscopic examination especially when aided by the urographic appearance of the kidney pelves and meters Systemic disorders such as the blood diseases, particularly the purpuras, are accompanied by hematuria but it is not uncommonly seen in acute or chronic nephritis We all know that acute nephritis is associated with red blood cells in the urine but that gross hematuria occurs in advanced chronic nephritis does not seem to be such common knowledge I have seen such patients bleed so much that the blood will clot in the urinal People with polycystic disease of the kidneys frequently complain of hematuria

With the more common causes for renal bleeding such as stone tumor, or tuberculosis, you are probably conversant However, not infrequently it may occur in acute kidney infections in the form either of a pyelitis or a papillitis and occasionally also, in cases of hydronephrosis, nephroptosis ureteral kinks or stricture

In the bladder itself, hematuria may be due to the presence of tumors (benign or malignant) stone acute infection ulcerations of one kind or another or last but by no means least, the ordinary benign adenomata of the prostate in which this is a finding in 40% of cases Bleeding from the urinary tract unlike that from the cervix or uterus is frequently an early sign of disease so that these patients when thoroughly examined, promptly and properly treated can as a rule be cured of their disease

Urine Examination

In conclusion I want to add just a few words about urine examination Many physicians are satisfied with the gross appearance of the urine and with a determination of the presence or absence of albumin and sugar Some go so far as to examine a centrifuged sediment for casts and they may incidentally notice some pus cells but the presence and character of an infection is left to the bacteriologist If, however, the centrifuged sediment of a specimen of urine is put on a glass slide dried and fixed over a flame, then stained with methylene blue and examined under the microscope (the work of but a few minutes) we can at once see pus cells and epithelial cells and we can recognize cocci and bacilli In this way we can without any delay or possible error get much nearer the true diagnosis Sometimes a perfectly clear specimen of urine will contain a surprising number of pus cells and organisms, occasionally as in a bacilluria just organisms and as in tuberculosis, pus cells alone On the other hand a very turbid urine may be found to be free from any inflammatory products and contain only phosphates carbonates, etc Thus, when we have examined the urine in this way, we are readily able to correlate the symptoms presented and so treat our patients far better by first correcting the underlying causes and then, if we are so fortunately situated that we are able to, we may attack the lesion directly

REMOVABLE LAG BOLTS FOR FRACTURE FIXATION

By H. J. KNICKERBOCKER, M.D., GENEVA, N. Y.

THE objects of the method to be described are, anatomical reposition of fragments, their maintenance in position until healing has sufficiently advanced to assure permanency, and the removal of the internal fixation apparatus without secondary operation. It is best suited to oblique fractures of long bones, but may be used to advantage in numerous other types.

The principle employed is that of the lag bolt which, when properly inserted, draws the fragments together and holds them firmly in apposition until union has advanced to a stage allowing the removal of the bolt. If accurate approximation is made and advantage taken of the irregularities of the fracture line, sufficient strength is secured to permit the use of a single bolt. Multiple bolts are seldom required in simple fractures.

The bolts are made in different gauges, each of which is available in several lengths. Each gauge is provided with a simple wrench fitting the nut as well as the squared end of the bolt. The large hand drill used is furnished with interchangeable, quick detachable chucks which materially shorten the operating time. The drill, screw and shaft are made integral, of rustless material, doing with one operation what often requires three or more when screws and plates are used. The incisions are shorter than are usually necessary where other forms of internal fixation are used. In making incisions care should be used in placing them so that if possible the bolt will lie without lateral pressure in the incision line. If this is not possible, the bolt can be inserted through a stab wound or lateral incision made through the soft tissues to avoid pressure necrosis.

Exposure of the fractured area, reposition of the fragments and their temporary maintenance by means of bone clamps is similar to that employed in the use of bone plates. In selecting a bolt of the proper size, care must be used, first to

get one of sufficient gauge that will hold firmly and not split the fragments while being placed; second to have one sufficiently long that it will, when in place, project beyond the skin level and not cause soft tissue pressure necrosis.

Having made the proper selection of bolt and determined that angulation in reference to the fragments which will give the best leverage, the proximal and distal cortices are drilled through until the end of the drill projects slightly beyond the bone at the exit hole. Care must be taken to protect the soft tissues, and also to insure that

ings or later. After closing the soft tissues, using absorbable sutures throughout, the projecting end of the bolt is wrapped about with loose gauze and a plaster cast applied.

When sufficient union has taken place to insure permanency of position of the fragments, a window is cut in the cast, the bolt removed, and fresh dressings applied. Evidence of drainage action of the bolt is almost always present. By the time the cast is removed, the soft tissues have entirely healed and little or no external evidence of the presence of the bolt is visible. If the bolt is left too long, a granulating sinus may require curetting. The holes through the bone are usually well under way in the process of filling in before any function of the part is indicated. A few weeks later they are seldom discoverable by x-ray. No instance of infection attributable to the bolt has been encountered in over fifty cases in which it has been used. Less callus formation than by any other method has been observed, a feature which is especially desirable in fractures near joints. The more accurate the approximation of the fragment, the less is the callus. No cases of failure to unite have been encountered, although diabetes and syphilis have been present in some cases. One case had both, besides being so obese that even a plaster cast afforded but poor immobilization.

THE TREATMENT OF NEUROSYPHILIS, OTHER THAN PARESIS, WITH MALARIA*

By ARNOLD PAIGE, M D, RAYMOND J RICKLOFF, M D, AND EARL D OSBORNE, M D, BUFFALO, N Y.

From the Department of Dermatology and Syphilology Buffalo City Hospital Earl D Osborne Chief and the private practice of Dr Earl D Osborne

DURING the past ten years the medical literature has been full of reports of the treatment of paresis with malaria therapy It has been generally agreed among experienced men in this field, that approximately fifty per cent of all cases of paresis go into a remission following the use of malaria therapy Of the fifty per cent of paretics that respond to this form of treatment, approximately seventy-five to eighty per cent have been found to become serologically negative at the end of four years It has always seemed to us, that, if this form of therapy is of such great value in the treatment of the most serious and fatal type of neurosyphilis, it should be of value in the treatment of earlier cases of neurosyphilis We refer particularly to early meningeal neurosyphilis occurring during or shortly after the primary and secondary stage and asymptomatic neurosyphilis of two to ten years duration With this in mind we have used fever therapy in one form or another in the treatment of all eligible cases of neurosyphilis referred to the department of Dermatology and Syphilology of the Buffalo City Hospital and in private practice during the past five years Our experience comprises the treatment of over four hundred patients with malaria therapy of which approximately fifty per cent were diagnosed neurosyphilis other than paresis

Our greatest difficulty in the compilation of satisfactory data has been the inability to follow up many of the patients who have been treated with this form of therapy In a large city hospital dispensary, a large percentage of the patients are in the floating population, coming and going from one city to another In spite of efficient social service follow-up, we have been unable to secure yearly follow-up examination in more than thirty per cent of these patients This compares favorably with the experience of the Essen Skin Clinic[1] in Hamburg and the Kyrle[2] clinic in Vienna whose percentages of follow-up examinations were twenty two and thirty-two per cent respectively However, in private practice our yearly follow-up has been at least ninety per cent efficient We feel that our experience has been wide enough and over a sufficient length of time to enable us to draw certain definite conclusions regarding the effectiveness of malaria therapy in neurosyphilis, other than paresis

In reviewing the foreign literature one is impressed with the great difficulty of drawing definite conclusions with which to compare the results obtained in Germany and Austria with those obtained in this country At the Essen Skin Clinic it was formerly the custom to give a full course of arsphenamine and bismuth, preceding the malaria therapy but recently the arsphenamine has been omitted Following the cessation of the malaria therapy two or three full courses of arsphenamine and bismuth were given The routine treatment in Kyrle's clinic in Vienna has consisted of a full course of arsphenamine and bismuth preceding the malaria and followed by two or three full courses In both clinics the number of malaria chills has varied from seven to ten whereas in this country the usual minimum has been twelve Regarding the statistics from Kyrle's clinic it is interesting to note that, in primary syphilis there were 31 per cent serological or clinical relapses and in secondary syphilis there was a blood Wassermann relapse of 37 4 per cent *in females and 52 4 per cent in males*, when the spinal fluid was negative, whereas, when the spinal fluid was positive, there was a serological relapse of 17 per cent in females and 19 5 per cent in males After the second year of infection there was a blood Wassermann relapse, in spinal fluid negative cases, of 30 per cent without exception, whereas, when the spinal fluid was positive, there was a serological relapse of 15 per cent Jacobs and Volwinkel[3] of the Essen Clinic concluded that malaria treatment in the secondary stage had not proved its value, but in the late stage it might give favorable results Kyrle believed that the time for malaria treatment was during the fourth to the sixth year after infection and he concluded that the treatment of syphilis by malaria in the early stages was of no greater advantage than energetic, combined treatment with arsphenamine and bismuth He also believed that a thorough course of malaria treatment was able to prevent the onset of late neurosyphilis when given in the late stage of the disease Jadassohn[4] *believed also that malaria treatment should not* be given in early cases but only in the late latent cases Jacobs and Volwinkel[3] of the Essen clinic were not as pessimistic as Kyrle,[2] nor is Ritter[5] of Hamburg and Heuck[6] of Munich They observed no relapses, serological or clinical However, this may be explained by the fact that, in Vienna, the patients received only one course of three grams of neoarsphenamine prior to the malaria and one course of three to six grams after the malaria No mention was made of the use of bismuth in Kyrle's clinic It is hard to compare the statistics of foreign writers with those of O I eary,[7] who secured eighty-two per cent serologic cures in patients with asymptomatic *neurosyphilis*, at the end of four years' observa-

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N Y, June 2 1930

tion following the malaria treatment. The foreign statistics are simply not comparable in any way because most of their checkups were done during the first or second year after the treatment and the patients received seven to ten chills compared to O'Leary's twelve to eighteen.

Choice of Cases

We agree with Cole[8] and O'Leary[9] that the proper choice of patient to receive fever therapy is the secret of a low mortality rate from this form of treatment. We are fully aware of the published mortality rates in the treatment of various classes of paretics, a mortality rate varying from two per cent in early paretics up to as high as thirty per cent in the treatment of the most advanced cases. We believe that a death rate of 30 per cent in far advanced cases of paresis is justifiable in view of the hopeless nature of the disease, but it most certainly is not justifiable in the treatment of the early cases of neurosyphilis. Recently, Stokes[10] has somewhat condemned the use of malaria therapy on the basis of its high mortality. Our figures agree with those of Cole[8] and O'Leary,[9] the former having a death rate of .5 per cent and the latter a death rate of 1 per cent. O'Leary[7] has recently stated that in his last two hundred cases the mortality rate was zero. Our death rate has been two per cent in paretics treated with malaria and one per cent in the treatment of cases other than paresis. Of these latter two patients, one died of acute diabetes which was not discovered until too late and the second patient died of a ruptured aneurism of the internal carotid artery prior to the onset of his malaria chills.

Contra-Indications to Malaria Therapy

In our choice of cases we have first submitted the patient to a careful general examination including liver and kidney functional tests as well as complete blood and urine examination. We have formulated the following list of contra-indications to malaria therapy:

1. Old age.
2. Marked arterio-sclerosis.
3. Advanced liver, myocardial and kidney diseases.
4. Severe anaemia and diabetes.
5. Ascending urinary infection.
6. Advanced aneurism.
7. Pregnancy.
8. Active tuberculosis.
9. Chronic alcoholism.
10. Rapidly progressive neurosyphilis.

Following inoculation, we have found it necessary to hospitalize all of our patients in dispensary practice, whereas, in private practice, we were able to allow them to return home until the day following the first malarial paroxysm. In this way the cost of the treatment was materially reduced for those in very moderate circumstances. This is a factor of prime importance in the economic consideration of this type of treatment.

Routine Examinations

We have allowed all of our patients, whenever possible, to have a minimum of twelve up to a maximum of eighteen chills. During the period of active malaria we do the following tests routinely:

1. A daily blood pressure determination. If the systolic pressure falls below 75 mm. of mercury, the malaria is immediately stopped.
2. Blood urea and urea nitrogen determination. If the blood urea rises to 75 mg. per 100 cc. of blood, the malaria is immediately stopped.
3. Tri-weekly red blood cell count, haemoglobin and urine examination.
4. Frequent palpation of the abdomen for any signs of enlargement of the liver and spleen and inspection of the sclerae for the earliest signs of jaundice. Marked enlargement of the liver and spleen does not occur in more than 5 to 10 per cent of cases in our experience.
5. Vandenberg and icteric index determination bi-weekly.

We feel certain that careful attention to the above-mentioned points together with personal examination of the patient each day, will reduce the mortality rate from malaria therapy to one per cent or less.

Economic Status

In addition to the hgh mortality claimed for malaria therapy by some authors, it has also been pointed out that it is too costly, both in time and money, for the average individual in moderate circumstances. We strongly disagree with this point of view. The average stay in the hospital is four to five weeks. For a semi-private bed the hospital charge averages five dollars per day, or one hundred and fifty dollars for a full month. Add to this, the moderate medical charge of one hundred and fifty dollars, making a total of three hundred dollars. The individual is usually kept from his work for approximately eight weeks. Contrast this with the treatment with tryparsamide, as recommended by Solomon[11] and Stokes,[10] of eighty to a hundred and twenty intravenous injections of tryparsamide, or thirty Swift-Ellis intraspinal treatments. We have seldom found the cost of malaria treatment to a poor person or to one in moderate circumstances to be a bar to this form of treatment.

Treatment Administered Prior to Malaria

We believe that all patients with early meningeal neurosyphilis should receive at least one full intensive course of treatment of arsphenamine and bismuth prior to malaria therapy. This opin-

ion is supported by those of Jacobs and Vohwinkel,[1] Kerl,[2] Mulzer,[3] Jadassohn[4] and O'Leary.[7]

Treatment Administered After Malaria

In early neurosyphilis, we believe that a minimum of two to three courses of arsphenamine and bismuth therapy should be administered after the malaria therapy has been completed. We usually do not begin this treatment for three months after the malaria therapy. In late neurosyphilis, including the asymptomatic and tabes dorsalis, we have routinely employed long courses of forty to sixty injections of tryparsamide combined with bismuth. We are not able to say at the present time that the use of tryparsamide in these cases offers any advantage over the use of arsphenamine. In most instances, however, the patients have had a large number of arsphenamine injections before consulting us. In view of the beneficial effect of tryparsamide in late neurosyphilis, we have felt that it should be combined with the malaria therapy rather than the continued use of arsphenamine.

Results of Malaria Therapy

As stated previously, we have analyzed the results in the treatment of two hundred patients with neurosyphilis, other than paresis. One hundred of these patients have received their treatment more than a year ago. The average was nineteen months. Of those analyzed 35 per cent had negative blood Wassermanns and in 29 per cent the spinal fluid was negative. It is evident from these figures that from a serological standpoint we are far from the figures of O'Leary[7] who reported 82 per cent serologic cures at the end of four years' observation following malaria. Evidently the period of greatest improvement in serology is from the second to the fourth year following treatment. It is also evident from our figures that a somewhat higher percentage of the blood Wassermanns became negative than of the spinal fluids. This is in contrast with the figures of the Essen Skin Clinic[1] and Kyrle's clinic[5] which reported the reverse to be true. Based on this observation we have, during the past two years, treated a number of Wassermann-fast cases with negative spinal fluids. In two patients sufficient time has elapsed for a recheck of the blood and in both instances the tests were completely negative. Chart I illustrates one of these cases and is self explanatory. This young lady with congenital syphilis had never had a negative blood test for a period of three years prior to our examination and from July, 1926 to March, 1929 had four strongly positive Kolmer and Kahn tests. The first negative test which she ever had, came eight months following the malaria treatment. Gougerot and Throlon,[13] in 1928, reported two similar Wassermann-fast cases brought to negative with fever therapy.

Early Meningeal Neurosyphilis Occurring During the Primary and Secondary Stages

In view of the findings of European investigators, as mentioned heretofore, we have not treated any of the patients with malaria until they have had a thorough treatment consisting of at least two or three courses of arsphenamine combined with bismuth. We still believe that the Swift-Ellis intraspinal therapy is extremely efficient in these early cases, but, if it can be shown that malaria is just as effective it would be more preferable from an economic standpoint. From our experience we favor the administration of two or three intensive courses of arsphenamine and bismuth followed by malaria therapy. We do not believe that malaria should be used during the first two years of the infection. Chart II illustrates a case of early meningeal neurosyphilis treated with malaria. He came to us with a history of a chancre one year previously for which he had received fifteen intravenous injections. His blood was strongly positive. He received a routine course of arsphenamine at the end of which the spinal fluid examination was very strongly positive. He then received eight intraspinal treatments at the end of which his spinal fluid was still strongly positive. This was followed by malaria treatment and thirteen months later his blood and spinal fluid were negative.

ASYMPTOMATIC NEUROSYPHILIS

We believe this class of patient is ideal for malaria therapy inasmuch as most of them fall in the period of two to six years following their infection. This is another strong argument for the routine examination of the spinal fluid in every case of syphilis, in the early and latent stages as well as the late stage. Chart III illustrates an excellent result in this type of case. This woman was the mother of the young lady whose treatment record appears in Chart I. Attention is called to the fact that there was a relapse in the spinal fluid which one year later was entirely negative without any further treatment. Chart IV illustrates another case in which a positive spinal fluid was found in the course of a routine spinal fluid examination. Thirteen months later the spinal fluid was completely negative and two years later the blood became completely negative.

LATE NEUROSYPHILIS, OTHER THAN PARESIS

In these cases the symptomatic improvement was the outstanding feature of the malaria therapy. Frequently, route pains were intensified during the first three or four malaria chills but gradually lessened in severity and disappeared altogether before the treatment was finished. Crises of various types are similarly effected in many instances. The patients almost always feel better generally and have a different outlook on life. Oftentimes the patient will say that he feels like an entirely different person. Chart V shows an illustrative case of long standing. There was no response whatsoever to intraspinal therapy and there was rapid symptomatic progression of the disease. The beneficial effect from malaria was marked and immediate. His spinal fluid was not entirely negative a year and a half after the treatment. Chart VI illustrates an advanced case of meningovascular neurosyphilis. Note that the disease was of four years' standing. The serology was completely negative at the end of fifteen months following the malaria therapy.

With regard to primary optic atrophy, we have treated a number of cases with very gratifying

results. Up until the last year we have treated these patients with intraspinal therapy followed by malaria. More recently we have used malaria alone followed by arsphenamine and bismuth. Sufficient time has not elapsed to evaluate our results. Of three patients who have been checked up serologically one year following the fever therapy, none has shown any progression in the subjective or objective findings, and none of the spinal fluids have, as yet, become serologically negative, Chart VII gives the details of an illustrative case. The patient was treated with typhoid vaccine intravenously because we were unable to get a postive inoculation with Plasmodium vivax. His blood became negative a year and a half following the fever therapy and has since remained negative. At the end of over three years his spinal fluid was still positive but his vision has been stationary and he has felt fine.

There is one important question which has not as yet been answered although there are some data on the subject. This question is: Does malaria therapy prevent the later development of paresis or tabes dorsalis when given during the early asymptomatic or latent stage? We know of no cases reported except those of Thurzo and Nagy. This is obviously a very important question in the evaluation of malaria therapy and will require years of observation before definite conclusions can be reached.

Conclusion

We believe that malaria or some other method of fever therapy is a valuable adjunct in the treatment of neurosyphilis. From a study of the literature and our own experience we believe the ideal time for malaria therapy is from the second to the sixth year of infection. We believe that the percentage of serologic cures will gradually decline in proportion to the duration of the infection. Malaria therapy should be preceded by adequate arsphenamine and bismuth to the extent of at least two or three full courses and followed likewise by arsphenamine, bismuth or tryparsamide as indicated. With a thorough understanding of the applications and limitations of malaria therapy, it is a safe and efficient method of treatment.

IDIOPATHIC DETACHMENT OF THE RETINA AND ITS TREATMENT*

By EDMOND E. BLAAUW, M.D., BUFFALO, N. Y.

"Un sujet si complexe mais si important."

GONIN'S name has recently become quite popular in ophthalmology. This is deservedly due to his perseverance, and he has been crowned with success. His igni-puncture in detachment of the retina is comparable to the iridectomy in glaucoma, which has made the name Albrecht von Graefe immortal. Detachment of the retina has been regarded as a Crux Medicorum with an almost desperate outlook. All previous treatments have failed. Gonin's igni-puncture has raised the chances of cure from one percent to at least fifty percent. This does not allow us to neglect the study of the old problem of so-called idiopathic detachment of the retina.

This is one of the most distressing maladies with which we come in contact. Although this condition may be found at all ages even in the newborn, it most frequently is encountered during the more active period of life. As a thunderbolt out of a clear sky this malady may develop within a few hours. In some patients prodromal symptoms may be present for days and weeks before the final loss of sight. The course of the process can not be predicted. Localized detachments may remain unaltered for years but usually they become total.

The literature is abundant, case reports, especially the favorable ones are numerous. One of the most important contributions is made by Theodore Leber in the von Graefe-Saemisch hand-book, second edition. It appeared in 1913 and covers 259 pages. We find in it all details as to pathogeny and treatment and it may be considered as known property of my auditors. Only a few salient points must be recapitulated. Under the diagnosis "primary detachment" two great classes are included—those where the detachment comes from behind the chorioid and those where the causal factor is found in front of the retina. This will be mostly a pre-retinitis which begins in the ciliary body, resp. the orbiculus ciliaris without serious complication of the vitreous body. The vitreous body may be primarily affected—in these cases tears are to be found in the retina. Leber insists that these tears must be present and particularly mentions the large ones near the ora serrata.

During the last few years there has been an increased interest in the subject. It is therefore proper to describe Gonin's views. I find his great interest in this condition dates from before 1904, when he relates the frequent findings of rents or holes in the retina in connection with a detachment. For Myopic (of every degree) and senile eyes the process seems to start with a retraction or detachment of the vitreous body from behind. We cannot fancy such an occurrence unless a pre-existing but undetected chorioiditis is present. Because of the disturbed nutrition of the vitreous body, the connective tissue part of the vitreous condenses in its forward zones behind the lens, while the posterior part of the cavity fills with an expressed aqueous fluid. This condensed vitreous tissue becomes invaded with epithelial cells, partly pigmented, from the ciliary body and forms connections with the retina or more diffuse membranous strands. Localized chorioretinitic processes may favor adhesions with the wall. The retina becomes torn through contractions of these strands. This opening (the tear) allows the vitreous fluid to undermine the retina and lift the membrane from its pigment-layer. The vision becomes disturbed, the patient consults the ophthalmologist, who diagnoses a detachment. The opening which allows this contact between the pre-retinal and retro-retinal space must be closed. This is done with a perforating igni-puncture, which if successful cements the sclero-chorioido-retinal layers and the vitreous body. The chorioid takes care of the retro-retinal fluid and the retina again becomes readapted against the pigmented layer.

Most of the theoretical conceptions have been formed after microscopical studies. When Gonin published his first article he had examined three cases of idiopathic detachment which brought the number to eight. It should be understood that these eyes were removed because of subsequent irido-cyclitis or glaucoma.

But whatever the theory—the rent was the great damaging agent and its communication had to be blocked. In 1913 Gonin performed a penetrating igni-puncture, when no rent was found and had success—the retina became readapted. From 1920 on he has continued with increasing success. Leber has stated "the detachment arises with the tear" but he did not think that production of a chorio-retinitic synechia was necessary—had there not been many procedures partly successful where puncture of the retina with withdrawal of the sub-retinal fluid was a part of the procedure, so that an opening in the displaced retina was considered favorable because it diminished its tension. Leber had come to the conclusion that the therapy should be more aggressive, that the puncture should be made while the detachment is recent. We should not wait until the fluid has gravitated.

Penetrating thermo-cautery punctures have been performed in 1881 and 1882 by de Wecker and Masselon and Abadie in Paris and although successes were registered the method was abandoned, because the results could not be foreseen.

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 3, 1931. Illustrated with lantern slides.

Experiments on animals by Wernicke in 1906 showed that an adherent scar could be produced, though a detachment followed in the opposite direction. In 1920 Gonin presented his Referat before the French Opht. Soc. at its annual meeting: "Pathogénie et Anatomie pathologique des Décollements rétiniens." In this work he confirms the pull on the inner side of the retina with the predominant role of the vitreous body and the importance of the retinal tear. By careful ophthalmoscopy one usually finds the tear. (In his last communication 1930 he finds it in 96%.) When a tear cannot be found it must be considered to be in the most peripherical region where we cannot penetrate with the ophthalmoscope. In 1921 Gonin published, in the Ann.d'Oc.p.175 :le traitement du décollement rétinien, wherein he expresses the possibility to reattachment of the retina if one is able to close the causal tear and cause adherence of the retina to the bulbar wall by means of scar tissue. Of course he is somewhat hesitant and considers it a last resort. We soon see him lose his hesitancy and attack an only remaining eye. He describes a most careful ophthalmological examination, not only for finding the tear (meridian after meridian, from the disc to the nearest point toward the ora serrata) but also of the vitreous (deductions from microscopical findings do not inform us about the living vitreous). According to Gonin the prognosis of the detachment is determined by the vitreous. He considers the pathogeny of the detachment very complex. The vitreous changes are related to chorioidal changes. It is very probable that the underlying uveal changes are dependent on changes in the general condition of the patient. He considers (and not he alone) the detachment as a disease with a simultaneous local and general character. It seems slightly a contradiction that Gonin concentrates his attack to a so local part of the process—but by this he has been able to preserve many patients from blindness.

We then come to the conclusion that detachment of the retina must be considered as an episode in the course of a chronic disease of the eye. This process in the eye begins in the periphery of the chorioid and ends with the total retinal detachment, shrinking of the retina, often with iridocyclitis, cataract formation, secondary glaucoma or phthisis bulbi. We know that the chorioidea can become affected through Syphilis, Tuberculosis, Rheuma and Gout, and foci of infection. We must therefore examine the body and these underlying factors should be treated. We may go further and take advantage of the absorbent power of mercurial inunctions though syphilis may be absent, as soon as evidences of peripheral chorioiditis are recognized.

When the examination has shown that the eye will respond to igni-puncture, a detailed drawing of the findings must be made, the meridian localized, marked with dots at opposite sides of the limbus, then the parallel circle or distance from the ora serrata; that is the farthest point nearest to the cornea which we can see. The disc diameter serves as measure, 1,5 mm long. The number is added to 8 mm the distance from the limbus, a little more in high myopia (9 mm) a little less in hypermetropia (7 mm). At the nasal side the distance of the ora serrata from the limbus is slightly larger. The cord may be taken for the curve. The igni-puncture is made to include the adherent part of the vitreous.

The after-treatment is of much importance. The heavy part of the vitreous should rest on the cauterized part of the wall, so if the tear is above, the patient lies as flat as possible with raised feet, while with a low tear the head should be slightly raised or when the tear is in the side of the eye the patient must lie on that side. He should remain as immobile as possible for about a week. The eye should not be examined ophthalmoscopically before the sixth day. Igni-puncture may have to be repeated.

The traction theory had not found many advocates in the profession. It is no wonder that in the discussion in 1920 Gilbert Sourdille, Professor in Nantes opposed it. He has not changed his theoretical view, which with a report of his successful cases has lately been published by his son, Gabriel P.S. in his doctorate thesis "Succès Opératoires dans le Traitement du décollement rétinien" with a much suggestive subtitle "est-il indispensable d'obturer la déchirure?" He does not accept the traction theory and the great importance of the retinal tear, arguing from the fact that the etiologic factors of a detachment are multiplex, often systemic and its prevalence in myopia, that bands are never seen with the ophthalmoscope and that tears are often absent. He does not deny the important role of the vitreous tissue, but considers this the result of lesions in the chorioid and retina.

The cells of the pigment layer form tufts in which the outer segments of the rods and cones are anchored. These cells become changed through the influence of a lesion or circulatory disturbance in the chorioid, not only in myopia and old age but also in those obscure cases where the patient suffers from a general affection: Nephritis, Aortitis or arterial hypertension. Adherence to the retina is endangered, a detachment becomes imminent. The primary changes are established in the choriocapillaris; this layer should be influenced. The retroretinal fluid is as a rule formed consecutive to the detachment. In the great majority it has a chorioidal origin; it is often a transudate or it may be an exudate. The vitreous changes are secondary. One is astonished by the frequent finding of advanced sclerosis of the arterial vessels and capillaries of the chorioid in old people especially in the equatorial region. Sourdille's aim is to restore the lost adhesions of both retinal parts by the formation of new ad-

lesions between the choroid and retina These changes must be limited to the strictly necessary areas The retroretinal fluid must be evacuated, so that the retina by its own weight may fall back to its original site The technical difficulty is to produce a sufficient but not excessive cicatricial adherence The permeability of the retinal vessels also has suffered They are prone to produce fluid even in the absence of any pronounced serious choroiditis Sourdille prefers to use the small galvanocautery loupe and injections of 1-1000 cyanide of Hg These are given when the detachment is extensive, they are painful (novocain, acoin, allonal—no morphine)

The galvanocautery is used in small detachments where at the most three punctures will be required and where the detachment is only slight The retina must be perforated but the penetration should not exceed a distance of two to three mm The adhesive reaction must take in the entire extent of the detachment The maximal intensity must be directed toward the most exposed point, to guard against reoccurrence This is the upper part of the detachment where the weight of the retina and the intensity of the lesions create a zone of less resistance and thus the incipience of the process The determination of the upper limit is very difficult The reapplication of the retina in the upper bulbar part after the retroretinal fluid has gravitated downward is not a true adherence At the tear the epithelium has suffered most A white spot with more or less pigment is a sign of retinal atrophy, the result of vascular changes of the choroid The black spots may also be the result of the detachment The evacuation of the retroretinal fluid should be as complete as possible The evacuation with the initial puncture of the sclera is insufficient, because the fluid reforms rapidly and the sclerochoroidal opening closes quickly, therefore the retina must be perforated systematically so that the retroretinal fluid may drain into the vitreous space

Complete immobility must cause the heavier retina to fall back on the choroid and remain there as long as the reaction lasts This is aided by a binocular non compressive bandage worn for six to eight days

The number of punctures made depends on the extent of the ablatio With a total detachment four punctures are made in the four meridians between the muscles at a distance of fifteen to eighteen mm from the limbus, never less than 12 mm and avoiding the vortex veins Even in partial detachment multiple punctures must be made These are made with a V Graefe's knife or a modification (S's sclerotome) in a meridial plane, the cutting edge forward, stabbing without cutting so deep that the retina is perforated, at least one cm Small turning motions will let the fluid escape under the conjunctiva Then opposite each opening made a few drops of 1-1000 cyanide of Hg with novocain are injected The novocain may be replaced by Acoin which produces an analgesia of from 10-12 hours The galvanocautery performations are made au rouge vif, the point must not penetrate more than 2 to 3 mm and is removed after 1 to 2 seconds The patient is to lie flat on the back for total and macular detachments without pillow, besides as in Gonin's after-treatment The eye remains under atropine (and dionin) The same for the first ophthalmoscopic examination It may be advantageous for the prevention of reoccurrences and after the application of cyanide of Hg to make a capitonnage electrolytique to increase the adhesions Five or six of the finest straight needles are introduced deep in through the sclera and connected with the positive pole of an apparatus for electrolysis During 5 to 6 seconds a 2 to 3 milliampere current is passed through This must be followed with a binocular bandage for at least 48 hours If the vitreous is clouded 5% sodium chlorine injections or a 1-5000 to a 1-3000 cyanide of Hg are given subconjunctivally once or twice a week

General treatment is always associated with the surgical, with myopia intravenous injections of cyanide of Hg, with a detachment of circulatory origin as in old people, with emmetropia Acécome, nitrites, iodium, with a nitrogenous retention (azoteme) strict diet with lactose drips per rectum The decubitus should be maintained at least for a fortnight Sourdille has to his credit 71 cures and 6 important improvements among 169 operations 19 of his successes were with detachments older than 3 months and 9 older than 6 months

To further understand the diversity of the predetachment process the study of Kummell's (Hamburg) contributions should be read The bulbar tension which in acute cases is often found low should be recorded This explains the danger of compressive bandage as a form of treatment We see in Lagrange's advocacy of colmatage the practical application of these observations For Kummell the tear is the result of pressure from behind and is secondary This does not mean that the tear is of no consequence To the contrary, the tear must be closed as a first indication for reapposition of the retina

The Diagnosis

The diagnosis of a detached retina is not always easy and often is not made as Elschnig and Axenfeld mention Instead of the red fundus reflex the color is more grey because the neural parts become destroyed and the connecting tissue proliferates The reflex is bluish or greenish grey sometimes glittering or may be white or bluish white We have a flat detachment which has fairly well retained its transparency and no shrinking or difference in color is observed Sometimes the disc and surrounding retina show the picture of diffuse retinitis and a superficial examination may miss the detachment The color is darkest

in haemorrhagic detachment, it may be greenish and but little light emerges from the fundus even with a dilated pupil. The examination with red-free light shows increased light reflexes from the retina and small folds and a slight turbidity. It is of special value where only a little fluid has lifted a large retinal area. Even then the transparency may remain for some time. In a beginning detachment at the posterior pole and the macula the red-free light shows folding of the limitans interna by characteristic reflex lines.

The reduction of the transparency is no indication of the age of the detachment, because the detached retina can remain transparent for years, while in a recent detachment the retina may appear white. The red reflex from the chorioid with transparent detachment is slightly diminished, while with a tumor the reflex is more grey or white.

The ophthalmoscope shows us a more fluid vitreous and disorganization in myopia and old age. The fibrillar tissue has become delisquent contracted and separated from the fluid part. This retraction of the vitreous begins posteriorly. Gonin notes greyish black opacities often in myopic eyes with retinal detachment, quite a distance in front of the disc (parallaxis). These he also found in high myopia without detachment and considers them as expression of detached posterior surface with forward retracted vitreous body. Amsler calls attention to a round or oval opening surrounded by a ring-shaped opacity through which the fundus details may be seen with striking distinctness (Kraupa 1914; Pillat 1922 have described and verified this) presenting a strong parallaxis with the fundus. This represents the posterior insertion of the hyaloid membrane into the disc surroundings which has become detached. If changes in the chorioid and retina are found at the same time a retinal detachment may be imminent.

An entirely different picture is seen at the periphery: there are greyish-white opacities or bands parallel to the ora serrata which reveal a densification of the hyaloid tissue; pigmented elements may be enclosed probably due to a migration of epithelial elements of the ciliary region or may be remnants of hemorrhages. They have an unfavorable prognosis in an eye without detachment. In front of retinal holes, small nodules or cotton-like masses can be observed which appear as being a torn-away fragment of the retina. If they are more white and numerous hanging in the vitreous—in an older detachment they may be fibrin remnants of old hemorrhages.

Epithelial bands which have been found in recent retinal detachment may be seen ophthalmoscopically as shinning lines on the anterior surface of the retina. Gonin does not consider these the primary cause of detachment. A diffuse vitreous change more pronounced in the central region has a rather infaust prognosis because it seems to express a generalized state of hyaloid retraction and a strong tendency to a hypotony.

Small retinal hemorrhages are frequently found in recent detachments in the neighborhood of a tear. They are not the result of the tear because they are not usually located at its margin. During a rapid extension of the detachment one may see an increase of hemorrhages. They may precede the detachment. A retinal hemorrhage is often the forerunner of a detachment which may follow some days later. If they are not traumatic they are from the chorioidea and due to circulatory disturbances (arterio-sclerosis, nephritis or diabetes). No sharp limitation exists between the spontaneous detachment and the one which follows profuse hemorrhages in the vitreous without traumatism or the one which is a late complication of a perforating wound with intra-ocular hemorrhage.

A word about retroretinal fluid. Different authors (Kümmell, Birch-Hirschfeld, Loewenstein, Baurmann) have found the retro fluid to be highly albuminous. Others consider it similar to the pre-retinal fluid. This fluid causes the gravitation of the detachment, if it begins in the upper part of the bulb, which happens in the majority of the cases.

The Tears.

Various forms have been found. They may be so small (from a diameter of 3/5ths of a disc to 12 disc diameters) that they simulate punctiform hemorrhages or so large that the retina is partly torn away. This occurs especially when the detachment begins below. There may be only one hole or they may be multiple in the same segment. At times a second hole is found in the opposite diameter. The folds of the retina may cover one another and thus hide the tear. In general the more recent the detachment the better the chance of finding the tear. Tears may develop secondarily after detachment. The deep red color of the chorioid and the distinctness of its vessels show the opening in the retina. Red-free light will show the margins in the retina opaque while the chorioid is black by contrast. Sometimes a flap is found in front of the retinal hole. Full dilatation is always necessary. "The tear must be found"—otherwise there can be no successful igni-puncture. (Gonin.) When the tear is open the margins produce a parallax with the chorioid.

Tears may be mistaken for hemorrhages—old chorioidal peripherical scars but these often have a pigmented border, blood vessels of the chorioid when they are broad and only visible for a short distance—or cystoid cavities—a tear has a sharper border.

Contraindications to Igni-puncture.

We must consider the patient from a general standpoint. The after-treatment consists of com-

plete rest for at least a week. This excludes very obese and old patients. The mental attitude and the social status are important.

In local conditions of the eye the most dangerous one is a manifest cyclitis and pronounced low tension. This and serious vitreous and retinal changes inform us that such eyes are too diseased. If no tear can be found, even if suspected, igni-puncture should not be attempted. In the large retinal detachment at the ora serrata the vitreous seems to play a prominent part. Gonin has recently attacked these retinal dialyses with some four or five punctures and thus has been more successful than previously. As a rule their prognosis is infaust, as well as the presence of multiple tears which must be the expression of a very disorganized retina. A pupil which does not dilate sufficiently, a too opaque medium, a too old detachment where the folds have become rigid through secondary processes; when the tear is too near the macula—these are all contraindications; when vitreous changes obscure the very fine retinal vessels which may be seen ophthalmoscopically as clear glittering small knobs: circumscribed synechiae between the vitreous and retina. Detachments after cataract operation have a bad prognosis if igni-puncture it attempted. Perforating igni-punctures are not without danger, they may destroy the last vestige of sight, more tears may originate or the vitreous may become more cloudy, hemorrhages may occur in the second week after the successful operation. This may be so because the clot becoming mobilized, later retinitis proliferans is found. Necrosis in the retina may appear with secondary perforations after or from igni-puncture.

Success may be expected when a single, typical, not too large retinal tear is found in the equatorial region, when a sextor shaped movable retina is found more or less connected with a tear, when the vitreous is only slightly cloudy, transparent especially before the extreme retinal periphery and when the anterior bulbar segment is free of irritation.

Indications will multiply with acquired experience. Gonin has turned the ophthalmologist away from the too pessimistic viewpoint of laisser aller, he has pointed the way to a more aggressive interference so that no unnecessary time is lost with indifferent measures and has demonstrated that early closure of the opening in the retina will in the great majority stop the progression of retinal displacement. For this he deserves the thanks of his Professional Brethren and of the victims of this ominous and so interesting calamity. Early recognition and early treatment will have to be learned by the medical profession as well as by the laity. Absolut fest steht bereits heute, dass die Goninsche Operation der Netzhautablösung einen wesentlichen Fortschritt bedeutet. A. E. Elschnig.

We call it a cure when the retina has returned to its previous place, although only rarely the function of the readapted part is entirely restored. In many cases the deterioration of the vision progresses while cases may exist where the detachment is permanent, but becomes demarcated with a much better prognosis as to the remaining vision. In highly myopic eyes linear scars will sometimes be found in the periphery which indicate a readaptation of a detached retina or where a detachment has become limited, apparently without damage to the rest of the eye. Observations where the retina became spontaneously readapted under peaceful measures notwithstanding the retina was perforated are not extremely rare although recurrences follow. (Arch. f. Aughk. 103 S. 271 A. Elschnig.)

Sven Larsson produced an adhesive chorioiditis with electro-endothermy (diathermy and electro coagulation). The sclera is carefully freed of blood after dissection of the conjunctiva away from the limbus including the area of detachment. The muscles in the field of operation are severed and sutured for replacement. A canthotomy may be done. The large negative electrode is put on the leg, a small one on the sclera (Acta Ophth. 8 S. 172).

Guist (Vienna) is trying to induce an adhesive chorioiditis with chemical agents. He attempts to perforate the chorioidea without loss of blood and then touches that spot with a Kaliätzstift; contact during one second showed experimentally no danger for the retina in animals. He has had six successive successes (One case was detachment after extractio lentis)—Ophth. Ges. Wien. December 16, 1930.

THE TREATMENT OF INFECTIONS

By HENRY S. MARTIN, M.D., and L. L. KLOSTERMYER, M.D., WARSAW, N. Y.

*Clinical Results Obtained with Blood Transfusions and Intravenous Injections of Mercurochrome—220 Soluble**

THE treatment of severe infections is probably exceeded in importance by no other subject in the practice of medicine. For many centuries physicians have put forth a vast amount of effort to overcome infections. Great progress has been made but the problem remains far from solved. When a sure cure for these conditions is discovered the practice of medicine and surgery will suddenly become one of comparative simplicity.

Green describes the function of blood as follows: "The life of human tissues is dependent upon the nutriment carried to the living cells by the blood stream, the removal of waste products or specific toxins, the maintenance of the vital chemical changes indispensable to normal functional activity and the supplying of stimuli, whether chemical or physical, such as are necessary to the normal processes of human life." If we accept his definition then it is reasonable to believe that a patient with anemia is not able to combat severe infection efficiently. Septic cases are always handicapped by a rapidly developing anemia and it follows that the nearer normal the patient's blood can be kept, the greater his chance of recovery.

Blood is a viscous fluid which remains in the circulation and aids greatly in the treatment of infection by its hemoglobin content, antibodies and activating substances. The benefit obtained is more indirect than direct, that is, the benefit is more from the effect of the blood upon the patient rather than its direct effect upon the bacteria.

By far the majority of writers on blood transfusion believe that it is of great value in the treatment of infection especially if anemia is present. Blood is a specific against surgical shock so it is indicated decidedly before and after major operations for severe infections. The patient in shock certainly has lessened resistance to infection.

With reference to the method of transfusion, we are partial to the Unger because it is efficient, the technique is simple and any amount of practically unaltered blood can be quickly transferred. The instrument which we use is the Unger apparatus as modified by Martin. However, we have no objection to any other efficient method providing that the transfusion be quickly and aseptically performed, unaltered blood used, and all of the blood definitely injected into the patient's vein.

The arguments against mercurochrome intravenously are especially that it causes harmful reactions and that it will not sterilize the blood stream. When mercurochrome is properly indicated, the reactions are usually insignificant. Deaths ascribable to mercurochrome are very rare. In our experience no deaths have resulted from the use of mercurochrome and autopsies on fatal cases of this series revealed no evidences of damage to kidneys or other parenchymatous organs. Walker and others state that mercurochrome exerts no bactericidal action when injected intravenously. Young and Hill also hold the same view. This by no means proves the measure worthless as many seem to believe.

Young, Sanner and Hill and many others may be cited who have convincing experimental and clinical evidence of the value of mercurochrome in infections. Mercurochrome influences the natural protective mechanism of the patient by stimulating antibody formation and increasing phagocytosis. Goldziehr and Peck found that the endothelial cells were stimulated to greater activity by the injection of colloids—the phagocytic power of the Kupffer cells increased following stimulation of the recituloendothelial system. Hill states that by emphasizing the reaction of the patient rather than the direct-killing of bacteria, we get on a satisfactory basis to explain why we get results in such a wide variety of infections.

Blood transfusions and mercurochrome are used as aids to the usual recognized treatment of infection and decidedly not as specific therapeutic measures. In severe cases of infection, a blood transfusion is given. On the following morning 1% mercurochrome solution is given intravenously. If the case is not extreme, not one of peritonitis, the toxemia not marked, and the hemoglobin not below 85%, the mercurochrome may be given first. In peritonitis cases, the blood transfusion is given always now on the day following operation. The mercurochrome is given twenty-four hours later. In our experience this sequence gives better clinical results for the reason that blood not only efficiently combats infection but is the best detoxicating agent, and thus the patient is better prepared to utilize the mercurochrome. A most important point in the use of these agents is that the patient must have a fair degree of resistance, that is, his powers of resistance to infection must not be paralyzed. Giving a moribund patient protein and a dye of even slight toxicity, is but an insult, for he is not able to utilize them.

Reactions following blood transfusions are more frequent in septic conditions than in clean cases. This is probably due to the comparative

* Read at the Annual Meeting of the Medical Society of the State of New York, at Rochester, N. Y., June 3, 1930.

inefficiency of the kidneys and liver to care for added protein and also to bacterial cleavage or lysis of bacteria by the bacteriolytic power of the donor's and patient's serum rather than to blood incompatibility. Ives reports one thousand transfusions without harm to the donors or patients. In our entire series of three hundred and fifty transfusions since January, 1926, reactions were 10% but none were alarming and there were no fatalities attributable to the transfusions.

Reactions (Figures 1 and 2) following one hundred and twenty consecutive injections of mercurochrome used alone were compared with reactions resulting from fifty consecutive injections of mercurochrome preceded by blood transfusions. The analysis shows that the blood transfusion-mercurochrome sequence reduced reactions as follows: The initial temperature rise was slightly less; the net fall somewhat greater.

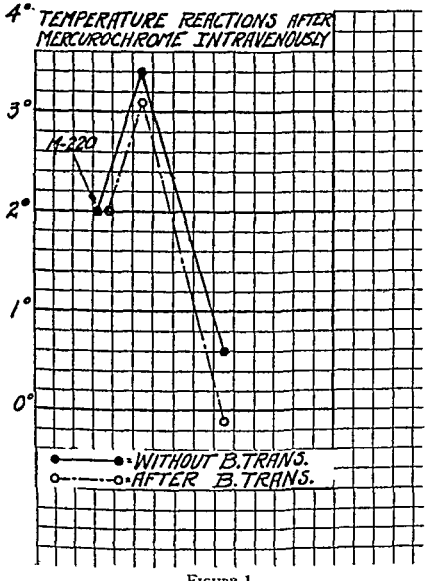

FIGURE 1

Temperature reactions following mercurochrome intravenously with and without blood transfusions.

Chills were reduced from 43.3% to 24%; severe chills from 17.2% to 2%. Vomiting reduced from 28% to 16%; severe vomiting from 7.2% to zero. Enteritis reduced from 32.4% to 10%; severe enteritis from 11.6% to zero. The reduction in enteritis is especially important in the treatment of peritonitis cases.

This résumé comprises 135 cases of various types of infection which we personally treated at

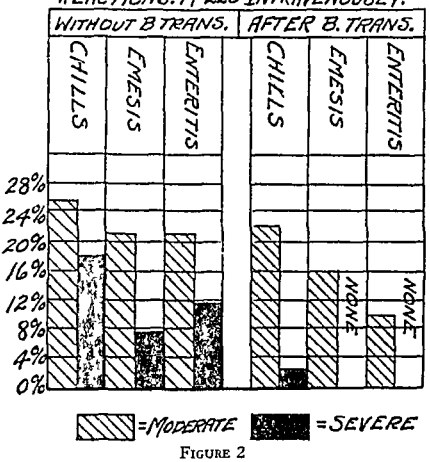

FIGURE 2

Comparing percent of chills, emesis and enteritis following mercurochrome intravenously with and without blood transfusion.

the Wyoming County Community Hospital. A summary of 75 cases which received mercurochrome injections but no transfusions, showed that: Prompt recoveries following injections of the dye were 33 or 44.2%. Total recoveries were 61 or 81.5%. Deaths were 14 or 18.5%.

In several cases mercurochrome seemed to be the deciding factor as regards recovery. Of the 14 cases which terminated fatally, 9 were complicated by bacteriemia, 2 were moribund and 1 was moribund with staphylococcic bacteriemia. The dye seemed to be of no value in streptococcus veridans endocarditis and in staphylococcic bacteriemias.

Results obtained in a series of 15 cases of bacteriemia treated by blood transfusion-mercurochrome sequence were: Recoveries 10 or 66.7%. Deaths 5 or 33.3%. Of the fatal cases 2 were of extreme cellulitis with pyarthrosis and 3 were of fulminating puerperal sepsis. One puerperal case admitted on the day following delivery, died four days later of metastatic streptococcic and staphylococcic abscesses—we know of no treatment which will favorably influence such a fulminating case. The treatment seemed to act especially well in 2 cases of septic sore throat and 2 cases of mastoiditis. All cases of the group were extreme.

In a summary of 60 cases of severe infection treated with transfusion-mercurochrome sequence: Prompt recoveries were 16 or 27.7%. Total recoveries were 48 or 80%. Deaths 12 or 20%. This summary includes a group of 25 cases of acute appendicitis complicated by diffuse

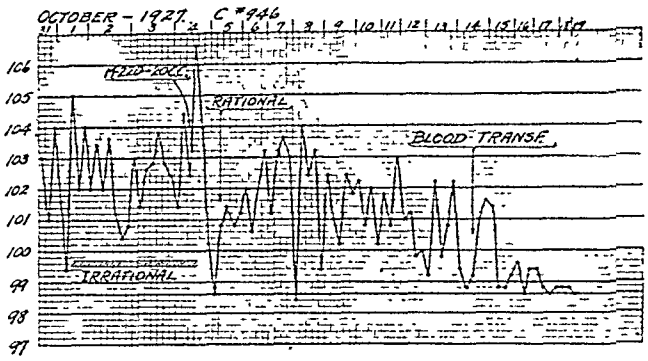

FIGURE 3

(Case No. 946.) Case of septic sore throat in a woman, age 42. One intravenous injection of mercurochrome resulted in considerable general and local improvement. Her condition then remained rather stationary until a transfusion was given. The temperature was normal on the following day and further convalescence was uneventful.

peritonitis or abscess. Of this group there were three deaths from general peritonitis. The value of the transfusion-mercurochrome sequence is evidenced by comparing this group with a similar group of 38 cases treated only by the usual recognized methods. Although the infections of the former group of appendicitis cases were more severe than those of the latter, the mortality was 12% as compared with 21%.

CONCLUSIONS

1. Both blood transfusions and intravenous injections of mercurochrome used independently are of definite value in the treatment of infection.
2. The favorable action of both blood transfusion and mercurochrome is due to increasing the patient's resistance to infection rather than to direct bactericidal power.
3. Blood transfusions and intravenous injections of mercurochrome are safe procedures provided the proper conditions and indications are present as regards both patient and physician.
4. Reactions following intravenous injections of mercurochrome are markedly lessened in frequency and severity when the mercurochrome is preceded by a blood transfusion.
5. The measures should be used early and repeated as often as indicated.
6. As an aid to the usual measures employed in the treatment of severe infections, the blood transfusion-mercurochrome sequence shows a distinct advantage over either blood transfusion or mercurochrome used independently.

It is impossible here to present more than a few briefly illustrated case records to demonstrate

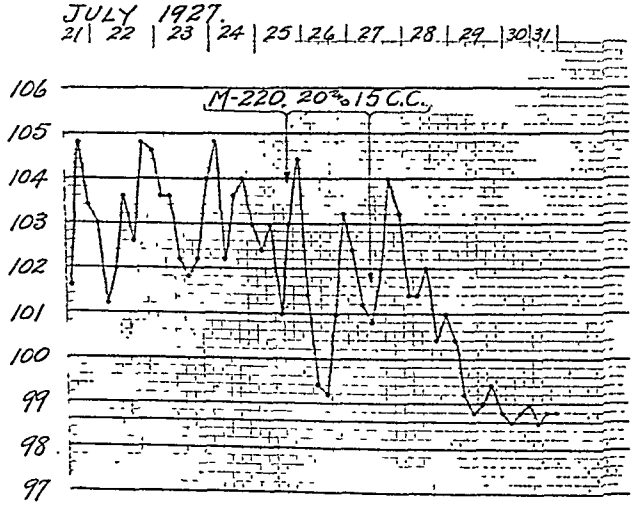

FIGURE 4

(Case No. 344.) Case of erysipelas of four days' duration in a man, age 37. Entire face and most of scalp extremely infected. Condition subsided rapidly after two intravenous injections of mercurochrome.

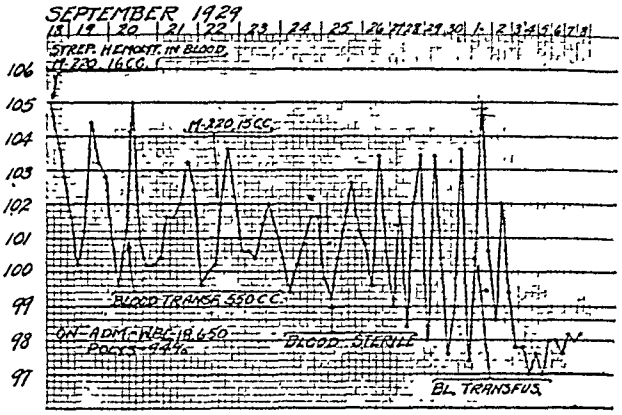

FIGURE 5

(Case No. 3626.) Woman, age 25, developed puerperal sepsis two days following an instrumental delivery. Admitted to the Hospital three days later. The blood culture was positive for streptococcus hemolyticus. The white blood cells were 18,650 with 94% polymorphonuclears. The hemoglobin was 55%. Given two transfusions and two injections of mercurochrome followed by recovery.

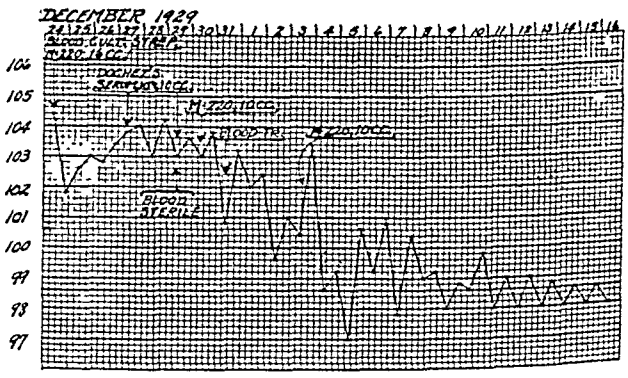

FIGURE 6

(Case No. 3866.) In this case of erysipeloid cellulitis with streptococcus bacteriemia in a youth of 18 years, the effect of blood transfusion and mercurochrome injections resulted in definite improvement but the two injections of Douchez's serum were of no benefit.

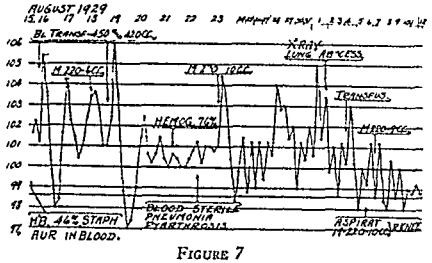

FIGURE 7

(Case No 3533) Boy, age 3½ years, developed a right peritonsillar abscess and left suppurative otitis media after two weeks of severe sore throat On admission the abscess was incised and drained No other surgery Blood culture positive for staphylococcus aureus Hemoglobin 46% Two abscesses of the right lung developed on the 13th and purulent synovitis of the right knee on the 19th hospital days Discharged fully recovered on the 33rd hospital day It is believed that transfusions and mercurochrome were responsible for his recovery

THE TREATMENT OF DERMATOPHYTOSIS*

By PAUL E. BECHET, M.D., NEW YORK, N. Y.

THE first scientific data obtained on dermatophytosis occurred as early as 1857, when Devergie[1] described an eruption on the groin which he called herpes inguinal, and described a microsporon as the causative factor. Hebra[2] in 1860 reported a similar eruption under the designation of eczema marginatum. Köbner,[3] Pick,[4] and Kaposi[5] confirmed the presence of a fungus in similar eruptions. Pellizari[6] in 1888 reported seven cases of ringworm of the hands. Djelaleddin-Mouktar[7] in 1892 gave the first description of the disease, reporting twenty-five cases, and in 1910 Sabourand[8] discovered that the fungus causing eczema marginatum, also caused a vesicular eruption on the hands and feet. Ormsby and Mitchell,[9] in a paper read before the Section of Dermatology of the American Medical Association, in June, 1916, were the first in this country to describe dermatophytosis. Strangely enough, this excellent paper, did not arouse the intense interest it should have elicited, because it was not until August, 1919, that White's article[10] appeared. In the interim I was able to note the report of only one case, presented by Cook[11] at a meeting of the Minnesota Dermatological Society on February 13th, 1917, and a letter from White[12] to the Editor of the *Journal of Cutaneous Diseases*, dated November 27, 1918, containing some personal observations on this, now well recognized, and wide-spread disease; which I venture to say, without fear of contradiction, presents at this time, our greatest therapeutic problem.

For the sake of brevity, I shall discuss the therapeusis of ringworm of the feet and hands only, and my main object in presenting this paper to the Section, is to stimulate research in the treatment of this most obstinate affection, as our present methods of treatment are far from satisfactory and leave much to be desired. Charles J. White[13] states "the local treatment of this disease has proved most disappointing and disconcerting to the patient and to the physician. The possible duration of the disease up to thirty years seems to corroborate this pessimism." This opinion is shared by many dermatologists and the more experience one gains in the treatment of this obstinate dermatosis, the less faith one has in our present methods of treatment. The complexity of the clinical manifestations of dermophytosis is fully equaled by the multiplicity of its therapeutic measures; there is not a single method of treatment which gives uniformly satisfactory results, what may almost act as a specific in one case, may dismally fail in another; the need for concerted effort to discover a specific, is therefore very pressing, and I ardently hope that one will soon be found; for there is hardly a single skin disease, which can incapacitate a patient more than a severe vesicular outbreak of dermophytosis.

It is hardly necessary before an audience of this character, to state that therapeutic measures

* Read at the Annual Meeting of the Medical Society of the State of New York, at Rochester, N. Y., June 3, 1931.

depend much on the stage of the disease. In the presence of an added acute eczematoid dermatitis one would certainly not use active keratolytic or fungicidal agents, on the other hand in the chronic, soggy, thickened stage, we are apt to be too cautious in using active agents. As the fungi are most numerous in the deep epithelial layers, the best hope of cure is to cause exfoliation of the epithelial layers as quickly and thoroughly as possible, and then use our fungicides; at times these two steps in treatment may be used simultaneously. Let us discuss briefly the better known therapeutic agents under separate headings.

Chemotherapy

Whitfield's ointment remains the most popular remedy in the treatment of ringworm of the extremities, and it is a very useful one despite the fact that it frequently fails. It is possible that some of its failures are due to two factors, its use in too weak concentrations, and its use in the presence of an eczematoid dermatitis, which condition it would tend to seriously aggravate. Its salicylic acid content is extremely valuable as a keratolytic, and in combination with benzoic acid has been demonstrated by Gould and Carter[14] to have a noticeable fungistatic effect on trichophyton interdigitale purpereum, and gypseum, the commonest fungi found between the toes. Schamberg and Kolmer[15] with a different series of fungi found that salicylic and benzoic acids gave relatively low fungistatic results, however, they used these acids separately, and on Trichophyton rosaceum, microsporon audouini, and achorion shoenlenii, a group of fungi relatively infrequent between the toes. These observers found that iodin transcended all other medicaments in restraining the growth of certain moulds. Yet it is a well-known fact that iodin is not a particularly brilliant remedy. Williams[16] reported the case of a boy who had used iodin on his toes for weeks, yet an enormous quantity of fungi was found. It may well be that the benefit derived from Whitfield's ointment is due to the exfoliation it produces, and not to any direct fungicidal action. As Highman[17] has pointed out the incorporation of fungicides in oil, cream, or ointment, diminishes their effect two to five fold, and in this opinion I heartily concur. Fungicides or keratolytics seem much more active in my hands when used in aqueous or alcoholic solutions. Wise[18] is apparently of the same opinion, as in a recent article on the subject, he advocates the use of alcoholic solutions of salicylic acid, and aqueous solutions of Liquor Burowii. Wet dressings of the latter are used as a preliminary to the application of salicylic acid, which is used in strengths of 20 to 30% as a desquamative. In vesicular trichophytids of the hands this solution is reduced to 10 or 15%, after thorough desquamation, a modification of Dreuw's chrysarobin ointment is used. These measures advocated by Wise are of gr value. In my own practice I use the chrysarol combination in chloroform or flexible collodion preference to an ointment base.

C. J. White[19] seems greatly impressed with value of a 2% aqueous solution of mercu chrome 220 soluble, painted on twice a day, fact he regards it as the most effective drug t he has used. Mitchell[20] speaks highly of the al holic solution of cinnamon oil and thymol, el orated by Myers and Thienes;[21] he believes it su rior to Whitfield's ointment. Kingery and A kisson[22] proved that an aqueous solution of thyr in a 1:1000 dilution was 100% fungicidal after minutes of contact with approximately 40 diff ent strains of fungi; even a minute's exposu killed 93%. Despite the fact that drugs may most active fungicides in vitro, yet lose much their power in vivo, thymol, on the face Kingery and Adkisson experiments, should given an extensive clinical trial. Sharlit a Highman[23] introduced tetraiodomethenamine flexible collodion. This drug is an unstable iodi compound, capable of giving off free iodine mo slowly than iodine crystals. It has not beco popular. Swartz, Blumgart and Altschule[24] us ethyl iodide vapor well diluted with air, using c.c. of the drug, and spreading the inhalation ti over about 20 minutes, administered daily. Seve teen cases of epidermophytosis were treate with exceedingly good results.

Castellani[25] recommends a saturated alcoho solution of basic fuchsin, with phenol, acetone a resorcin. It is applied daily to the affected par

Feldman and Ochs[26] reported most favorably the use of potassium permanganate in strengt ranging from 1:5,000, to the full saturated sol tion. White and Greenwood[27] also found it ve valuable. It would be interesting to note at th time that it was the favorite remedy of Dr. Duncan Bulkley some thirty years ago, in t treatment of vesicular eruptions of the hands a feet. I am also convinced of its value. Ruggles found the following ointment valuable.

Phenol .....grs	xv	(1)
Zinci, oxidi	5iss	(6)
Ung. picis liquidi	5iii	(12)
Ung. aqua rosae		5iuss (18

Radiotherapy

There seems to be no great amount of enthu siasm in the use of the *x*-ray in dermophytosi MacKee[29] in his text book states that all types o the disease react better to drugs than to irradia tion. Wise is also not optimistic. The results have obtained in uncomplicated dermophytosi are equally indifferent, but in the treatment of super added eczematoid dermatitis, and th

vesicular tricophytids of the hands, the *x*-rays in my experience have proved of great value.

Vaccinotherapy

The use of vaccines and trichophytin are in the early experimental stage, and it is therefore impossible to evaluate them. Mitchell has found trichophytin useless. On the other hand Van Dyck, Kingsbury, Throne and Myers[30] have treated 100 cases with intradermal injections of trichophytin with the following results:

Apparently cured	32
Greatly improved	28
Slightly improved	21
Unimproved	19

Résumé of Personal Experience

Extensive clinical observation has convinced me that eczematoid dermatitis is a most frequent complication of tinea of the feet and hands and that when it does occur it should be treated as an eczema; strong parasiticides only make matters worse. It is here that the *x*-rays are most useful. The method which gives me the greatest hope of possible cure in uncomplicated tineas is thorough exfoliation with strong alcoholic solutions of salicylic acid. When the skin has thoroughly peeled off parasiticides are applied, my favorites are thymol, potassium permanganate, chrysarobin, mercurochrome, and iodine preferably in solution. It seems to me that eventual therapeutic success is dependent, on long continued treatment rather than on any single remedy.

As prophylaxis against recurrences I would mention scrupulous cleanliness of the toes, and nails, the constant wearing of foot covering in public baths, gymnasia, etc., sterilization of socks, and even of shoes if possible. Desensitization with trichophytin may or may not have a sphere of usefulness; this must be left to future experimentation. I feel that the future specific for tinea of the feet and hands will be discovered through the elaboration of the methods of such pioneers in Chemotherapy as Schamberg, Kobner, Myers, Thienes, Kingery, and Adkisson, and that the new drug will be as successful in vivo as it will be in vitro. Vaccinotherapy will probably prove of no more value in this dermatologic "bête noir," than it has in other dermatoses.

In conclusion it may be stated that long therapeutic experience convinces one that none of the remedies heretofore used, have proved real specifics. They are, however, of considerable value. It is to be hoped that a real specific for this widespread affection will soon be discovered.

POPULAR MEDICAL PUBLICITY

The officers and committees of the Medical Society of the State of New York have given serious thought to the attitude of the people toward practitioners of medicine The people see on the one hand groups of scientific healers ranging from blatant quacks to those slightly trained in sectarian schools of therapeutics At the other extreme the people see physicians who have been trained in scientific medicine in universities and hospitals and licensed by the State after searching examinations The people do not always discriminate between these two groups or recognize the superiority of the trained physician

The methods of these two groups are diametrically opposed The quack and the healer practice intense salesmanship and promise results impos

MEDICAL PROGRESS

The Early Diagnosis and Early Treatment of Arteriolar (Essential) Hypertension.—David Ayman states that the early diagnosis (as well as the prevention) of essential hypertension has not yet been included in the active scope of modern medicine. This is due to four factors: (1) There is the fear of producing anxiety in the patient by too frequent blood pressure readings. This fear is unfounded, as it has been shown in a series of patients who took their own blood pressure readings for from two to three years that there were no harmful psychic results. (2) The lack of specific therapy has been a deterring factor in early diagnosis. As in other diseases in which there is no specific therapy, such as tuberculosis, success should be greatest in the treatment of early cases. (3) Delay in early diagnosis is due to the frequent, though unjustifiable, assumption that the disease commences in middle life. It has been shown, however, that in the history of a large percentage of hypertensive patients vasomotor symptoms began in early life. (4) Physicians, with the exception of those in insurance companies, do not consider with enough suspicion elevation of blood pressure mildly above the average in young persons. In people whose systolic or diastolic blood pressure is 10 mm. above the average, especially if they belong to a hypertensive family, the diagnosis of essential hypertension may be made, after all other possible causes of hypertension have been excluded.

One of the most important of the characteristics of essential hypertension is not the elevation of blood pressure but rather the fluctuation or variability of the blood pressure. In a group of 76 unselected hypertensive patients whom the author followed for a year and a half, 56 per cent at some time or other had a drop of their blood pressure to normal on resting. It is thus possible to have a normal blood pressure in essential hypertension. Joseph H. Pratt and the author have demonstrated that the symptoms associated with early hypertension are of psychic or vasomotor origin, and that they are found in dynamic individuals who always seem to be under tension. The therapy of early essential hypertension should, therefore, attempt a modification of the special dynamic hypertensive personality. The individual's pace must be slowed up. The necessity is for both mental and physical relaxation. The use of sedatives may afford assistance. Among the best and least expensive of these are the bromides, phenobarbital, and chloral hydrate. —*New England Journal of Medicine*, August 31, 1931, ccv, 9.

Treatment of Muscular Indurations by Novocaine.—Fred Wachsmann, writing in the *Deutsche medizinische Wochenschrift* of May 22, 1931, says that the dynamic equilibrium of persons engaging actively in sports is peculiarly labile. Especially in those undergoing a course of training is there a ready change from a state of sympathicotonia into that of an alkalinizing vagotonia. During strenuous training the muscle is hypotonic, but through disuse or wrongly dosed stimulation a state of hypertonia may set in, which offers a ready basis for an aftermath of local induration. There is a tendency now to assume that the sensory nerve endings become irritated by the exercise involved in steady devotion to sport, and also after hematomas, resulting in a spasm of the musculature, by which the muscles are shortened, and the glycogen metabolism is brought to a standstill, while the muscle function is diminished by accumulation of lactic acid and by readier susceptibility to fatigue. The muscles most affected are the triceps brachii, in ski-jumpers, the soleus in track-runners, the arm flexors in oarsmen, the pronator in tennis players, the shoulder muscles in gymnasts, the psoas in hurdle-jumpers, etc. In view of the difficulty of measuring the suitable dosage of massage, and the frequent failure of heat applications and hydrotherapy to relieve the indurations, Wachsmann has been trying the effect of small injections of novocaine made directly into the muscle affected. He has had brilliant results from injections of ½—2 c.c. (8 to 30 minims) of a 0.5 percent solution, occasionally using as much as 4 c.c. (60 minims). The reaction represents a kind of irritation therapy. In a total of 30 cases injected, he has found only 4 that did not yield to the treatment. A single injection has often proved sufficient, but in some cases 2 or 3 injections have been administered at 3 day intervals.

Control of Hiccough with Carbon Dioxide by a Simple Rebreathing Method.—Since there are reports in the literature showing that carbon dioxide, which acts directly upon the respiratory center, is a most reliable method of stopping hiccoughs, Lewis A. Golden urges that it be more extensively used. Because of the false assumption that its use demands an expensive and cumbersome apparatus, he describes a simple and readily available method which he has found quite effective. An ordinary paper bag of medium size and strength is placed over the patient's face, and held so that it tightly encloses the mouth and nose. The patient is instructed to breathe into the bag. As the available oxygen in the bag

is replaced, the exhaled carbon dioxide accumulates so that in several minutes there is enough to produce a therapeutic effect. Golden has treated six patients by this simple method. In one patient the hiccough, which had been continuous for two days, was checked in four minutes and up to the date of writing there had been no relapse. Of the other patients all but one were relieved in from three to six minutes. One had a recurrence several hours later, which he easily relieved at home by the same method.—*New England Journal of Medicine,* June 4, 1931, cciv, 23.

The Influence of Intercurrent Infectious Diseases upon Chronic Nephropathies.—Berta Aschner says that, among diseases that have been cured or remarkably improved by intercurrent attacks of acute infection, renal affections, especially chronic nephroses, hold an important place. Four cases are reported in which acute attacks of infection exerted a favorable influence upon chronic diseases of long duration. Two of these were cases of nephrosis, which either improved or were temporarily cured by attacks of erysipelas. In the first case a woman of 39 responded admirably to an attack of erysipelas involving the entire length of the right arm, after which she remained in excellent health for a period of 5 years. Upon recurrence of the nephrosis at the end of that time, however, no treatment of any kind, including protein therapy, was able to restore her to health. The second case was that of a man suffering with arteriosclerosis associated with high-grade albuminuria and hydrops. The urine was heavily loaded with white and red cells, and the albumin amounted to 18.5 per thousand. Here, too, an attack of erysipelas caused great temporary improvement, so that, although the patient died shortly afterward from cardiac and vascular complications, the astonishing fact was revealed at autopsy that there was neither grossly nor microscopically any least sign of renal pathology. There can be no doubt that we are dealing here with an autoprotein action, but attempts to apply this principle therapeutically by administering the usual forms of protein treatment proved wholly unsuccessful both in the author's cases and in one of Karacsony's, in which no effect could be produced either by peptone, nucleinic acid, or the patient's own serum. This is a field of effort in which no pains should be spared to achieve the results that have been attained in disease of the nervous system treated along these lines. The literature contains a number of other interesting examples of cases of chronic nephrosis which have been cured by acute infectious attacks, including croupous pneumonia, measles, and streptococcus peritonitis.—*Klinische Wochenschrift,* August 15, 1931.

The Value of Fever Produced by Diathermy in Multiple Sclerosis and Other Chronic Diseases.—William D. Schmidt and Benjamin P. Weiss emphasize the fact that of the various agencies used to raise the body temperature for therapeutic purposes diathermy is the only one which permits the physician to control the fever. The remarkable results obtained with diathermy in paresis led them to apply this form of treatment to other chronic neurological diseases—multiple sclerosis and encephalitis. In these affections also they have succeeded in obtaining remarkable clinical results, which were usually noted in from thirty to ninety days. While marked organic syndromes have cleared up to a marked degree, it is too early to predict permanence. Patients must be carefully selected for this form of treatment. Those of normal weight stand the treatment better than the obese, and women better than men. There should be no marked evidence of degeneration of the cardiac, renal, vascular or nervous systems, and the patient should not be over 50 years of age. During the treatment all the constitutional phenomena of fever appear, such as herpes, marked sweating, and leucocytosis. There is a rise in the ferment and antiferment content of the blood, increase in the metabolic rate, and an increase in resistance to invading micro-organisms. The treatment should be interrupted if the blood urea rises to 70 mg. per 100 c.c., if the systolic blood pressure falls below 35 m.m., if there is beginning bronchitis, muttering delirium, signs of pulmonary edema, weakened cardiac sound, or marked exhaustion, or if the thermoregulative center becomes unbalanced. In applying the diathermy an ordinary high frequency machine may be used, if it is sturdy enough to stand the strain of running for hours. The technique is that usually employed for the production of therapeutic fever by diathermy. The amperage is increased until it reaches 2,500 to 3,000 milliamperes, and maintained at this level until the desired temperature is attained. It usually requires about two hours and a half to elevate the temperature six degrees; the patient then remains covered for at least two hours. During the treatment a sedative is necessary. The authors use luminal, 1 grain, and bromides, 30 grains.—*Physical Therapeutics,* September, 1931, xlix, 8.

The Electrocardiogram in Congenital Disease of the Heart.—On the basis of a personal case M. Stejfa points out the importance of the electrogram in the diagnosis of congenital heart lesions. Only by this means was it possible to make a diagnosis of a perforation of the septum during the patient's life. The case was in addition characterized by a transposition of the large vessels and also of the ventricles, revealed at

autopsy, in a youth of 19. The electrocardiogram, which records the progression of electric phenomena, is in principle a functional method. But since its conformation depends also on anatomical circumstances, it is to some extent applicable in the diagnosis of congenital disease. It may furnish the following indications: (1) The intense systolic souffle with its maximum of intensity in the second left intercostal space beside the sternum, even when not accompanied by a murmur—given a pronounced right predominance, which cannot be explained in any other way clinically (as for example by kyphoscoliosis, mitral disease, sclerosis of lung or pleura, fibrous phthisis, etc.) may be regarded as a symptom of a congenital disease, without formal radioscopic confirmation. (2) When clinical examination leads one to suppose there is a congenital lesion of the heart (because of cyanosis and systolic heart murmur) and the electrocardiographic tracing is normal, a stricture of the pulmonary artery cannot be assumed, for in all the cases that have been verified at autopsy the predominance of the right heart had been established (except the author's own case with block of the right branch of Tawara). In these first cases, which have been defined by a normal electrocardiogram, we must rather assume the persistence of the arterial canal, or Roger's disease, or possibly lesions associated with atrophy of the right ventricle. (3) Following an electrocardiographic examination which establishes in a congenital affection an organic lesion of the bundle of His or of Tawara's branch, we may suspect a lesion of the interventricular septum. Since there are a number of symptoms which have not as yet been susceptible of diagnostic interpretation with complete certainty, because there are relatively few cases in which clinical examination can be controlled by autopsy, every physician who has made interesting findings by means of the electrocardiogram with reference to congenital heart lesions should make it a point to publish them for purposes of comparison.—*Archives des maladies du coeur, des vaisseaux et du sang,* August, 1931.

Pneumoperitoneum in the Treatment of Tuberculous Enterocolitis.—Andrew L. Banyai, writing in the *American Journal of the Medical Sciences,* September, 1931, clxxxii, 3, quotes figures showing that tuberculous disease of the intestines is far more frequently a complication of pulmonary tuberculosis than is generally realized. He states that the prognosis is not necessarily hopeless, and reports a series of 44 cases in which he has employed pneumoperitoneum, with resulting symptomatic relief in 31 (70.4 per cent.). In 14 cases relief was complete, in 10 partial, while in 5 diarrhea ceased though other symptoms persisted; diarrhea ceased while other symptoms persisted in 2 cases. The duration of symptomatic relief varied from a few days to two years. The technique of pneumoperitoneum is simple and without danger. The best site for the injection is three fingers' breadth below and to the left of the umbilicus; if fibrosis has resulted from this side having been used too often, the needle may be introduced at the same level on the right side. Manometer readings are taken during the injection, though this is not so important as in artificial pneumothorax. The subjective feeling of the patient, the distention of the abdomen, and increased intensity of tympanitic percussion sound are far better guides in controlling the amount of oxygen injected than the manometer. Positive pressure oscillations appear usually after 300 to 500 c.c. of oxygen have been introduced, though in some instances they are not evident even after 1000 c.c. of oxygen have been injected. The abdomen should be underinflated rather than overinflated. The treatment should not be given during menstruation. The thereapeutic effect of pneumoperitoneum is considered to be due to the direct chemical influence of oxygen, the increased intra-abdominal pressure, and the hyperemia of the peritoneum and intestinal serosa. A decrease in the peristalsis following oxygen inflations was noted in the majority of cases in this group. By these accomplishments one approaches the ideal aimed at in the treatment of any form of tuberculosis, that is, possible maximum immobilization with improved nutrition. The author feels that his results are sufficiently encouraging to warrant the more frequent use of pneumoperitoneum in the treatment of intestinal tuberculosis.

Hypertension and Inhalation of Pure Oxygen.—Experiments are reported by A. S. Berljand and Ch. J. Weinstein with reference to the effect of pure oxygen inhalation in that type of hypertension that is due to toxinfectious causes. The 25 subjects examined were chiefly diabetics, with a few arteriosclerotic patients and one suffering from nephritis. Ten normal persons were also used as controls. Three types of reaction were observed after inhalation of oxygen: (1) In normotonics, insignificant rise of systolic and diastolic blood pressure, still evident 15-20 minutes afterwards. (2) In some hypertonics, an increase of blood pressure immediately after inhalation, falling in 15-20 minutes to a point below the original. (3) In other hypertonics, an immediate drop in blood pressure after inhalation, which remained constant 15-20 minutes after the experiment. In the days following, the pressure was usually lower than on the first day; toward the end of the observation, that is, 10-14 days later, it was appreciably less in 23 of the 25 patients than before the experiment was made. In normotonics there was no effect of any kind at the end of this period in the way of either in-

crease or decrease. The question whether oxygen is absolutely hypotonic in its action must therefore be answered in the negative. With regard to the mechanism of its action in hypertonics we may suppose that it counteracts some component of the increase of blood pressure, with a degree of energy proportional to the energy of such component in any given case. Carbon dioxide might be such a substance, stored up in the blood and acting as a vasoconstrictor. Hyperventilation would then cause a fall in blood pressure, in which case we might give the name hypercapnic to this type of hypertension. Certain authors have expressed the view that the fall of blood pressure is due to decrease of calcium ions, as the result of beginning alkalosis. The authors were unable to demonstrate any difference in the content in calcium ions before or after the oxygen inhalation. In cases of essential hypertonia, where some writers claim that calcium plays a great part, they could not observe any influence exerted by carbon dioxide. Whether these forms should be regarded as hypercapnic or anoxemic therefore remains uncertain at the present time.—*Münchener medizinische Wochenschrift,* August 28, 1931.

The Use of Wet Quinosol Dressings.—It is still a debated question, says Sigwald Bommer, in the *Deutsche medizinische Wochenscrift* of August 28, 1931, whether wet medicated dressings offer a satisfactory mode of treatment. If they are strong enough to kill the bacteria, they are liable to be injurious to the skin. Having found boric acid dressing irritating, and in conflict with a dietetic treatment he was using, he made comparative tests of these and quinosol dressings, placing one drug on the right upper arm and the other on the left, in 45 patients suffering with lupus vulgaris. He observed the effects of 4 different solutions: (1) 1-2000 in boiled tap water, (2) 1-1000 in the same, (3) 1-1000 in 0.85 per cent. sodium chloride solution, (4) 1-500 in the same. The boric acid was used in 3 and 1.5 per cent. solutions. Quinosol is sulphuric acid ortho-oxyquinoline-potassium, consisting of approximately equal parts by bulk of oxyquinoline and potassium bisulphate; it is chemically related to yatren. When the applications were made on sound skin in normal persons, there was no difference in the effect between the two substances. But in cases of ulcerated lupus vulgaris the superiority of quinosol was striking. In deep ulcers of hypertrophic lupus there was an astonishing decrease of secretion, with prompt drying up at the bottom and complete cicatrization in very brief time. In five of the patients there was a burning sensation for about 15 minutes after the dressing was applied. It followed invariably, being greater after solutions 1 and 2 than after 3 and 4. The sodium chloride has the effect of decreasing the burning sensation and the irritating effect of quinosol. In lupus vulgaris any irritation has the effect of increasing the inflammation, and is therefore to be sedulously avoided. Bommer believes that even the weaker solutions he has used are still somewhat too strong, and that a further decrease is desirable in many cases. In those who from the start tolerated the treatment without any difficulty, and who had closed foci or slightly hypertrophied lupus nodules, there was prompt disappearance of all inflammatory symptoms in the vicinity of the lupus nodules.

Influenza-Bacillus Endocarditis Assuming the Picture of Endocarditis Lenta.—In view of the fact that only 21 cases have been found in the literature in which a purulent endocarditis could be unequivocally attributed to the influenza bacillus, Heinz Frank believes that a case of his own offers points of special interest. A man of 32 had suffered with mitral insufficiency from early youth, certainly from the age of 12 years. He was first admitted for an acute inflammation of the hip joint in addition to this old lesion. The fact that the case yielded to salicylates in 3 days makes it safe to assume that the affection was rheumatic monarthritis. That endocarditis was present at this time is unbelievable, since the time required for sedimentation of blood corpuscles quickly rose to normal, the patient was apyretic and had gained 7 pounds. Two months later he was admitted again, with shortness of breath, slow fever, attacks of weakness, and a sense of general discomfort. All the signs of a septic endocarditis were present: anemia, enlarged spleen, intermittent fever, embolism, signs of focal nephritis. That this endocarditis was caused by influenza bacilli cannot be doubted, since these were found in the blood five times and cultured in pure culture, without other kinds of bacteria being demonstrable. The condition presented all the symptoms of the affection called by Schottmüller endocarditis lenta: an obscure beginning, long subfebrile to febrile temperatures, enlarged spleen, increasing anemia. In addition the fact that septic endocarditis established itself upon a valvular defect in an old rheumatic endocarditis is a very frequent finding in endocarditis lenta in the stricter sense of the word. The case was differentiated from true endocarditis lenta only by the fact that *Streptococcus viridans* could not be demonstrated in blood culture, but that influenza bacilli instead were present. The actual clinical findings were in no way different. All the 21 cases in the literature as reported by nine authors, have terminated fatally. It is therefore almost certain that endocarditis in which the influenza bacilli are demonstrated in the blood stream results in death of the patient.—*Münchener medizinische Wochenschrift,* September 4, 1931.

LEGAL

PHARMACIES—POWER OF STATE TO LEGISLATE ON QUESTION OF OWNERSHIP

By LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

In our large cities the old-fashioned apothecary shop is rapidly disappearing. The chain-store system of drug shops, in some cases extending over the entire country, has replaced the individual in this all-important field. The most important function of a pharmacist is the correct and accurate compounding of prescriptions written by a physician. The responsibility of a pharmacist in this respect is indeed great; if he errs, he is in a position not only to undo the work of the physician but to cause great suffering and even death to the patient. It is obvious that the practice of pharmacy is inextricably interwoven with the public health. In the State of New York the Statute (Education Law, Article 51) sets up a State Board of Pharmacy with powers of regulation, supervision and control over the practice of pharmacy. The statute sets forth the qualifications necessary before a pharmacist can be licensed and also provides for the revocation of such license in the event that the pharmacist should prove false to his trust.

The change in ownership and mode of operation of pharmacies and drug stores in connection with the growth and expansion of corporations in this country is responsible for the passing of statutes which provide, in substance, that no such store shall be owned or operated except by a licensed pharmacist or druggist. These statutes are not retro-active and hence do not apply to the ownership of pharmacies or drug stores which existed prior to the passage of the statutes in question.

In Pennsylvania a short time ago, the constitutionality of a statute of this general character was challenged by a corporation which operated a chain of drug stores. It was contended that the statute in question was unconstitutional in that it contravened the due process of law clause in the Fourteenth Amendment of the Constitution of the United States. The case was carried to the Supreme Court of the United States. The majority of that Court adopted the contention of the drug store corporation and held the statute unconstitutional on the record then before them. There was, however, a vigorous dissent by Mr. Justice Holmes, concurred in by Mr. Justice Brandeis. In taking the position that the act in question was constitutional, the learned Justice said:

"A standing criticism of the use of corporations in business is that it causes such business to be owned by people who do not know anything about it. Argument has not been supposed to be necessary in order to show that the divorce between the power of control and knowledge is an evil. The selling of drugs and poisons calls for knowledge in a high degree, and Pennsylvania after enacting a series of other safeguards has provided that in that matter the divorce shall not be allowed. Of course, notwithstanding the requirement that in the corporations hereafter formed all the stockholders shall be licensed pharmacists, it still would be possible for a stockholder to content himself with drawing dividends and to take no hand in the company's affairs. But obviously he would be more likely to observe the business with an intelligent eye than a casual investor who looked only to the standing of the stock in the market. The Constitution does not make it a condition of preventive legislation that it should work a perfect cure. It is enough if the questioned act has a manifest tendency to cure or at least to make the evil less."

In New York the statute with respect to the ownership of pharmacies and drug stores reads, so far as material:

"Every pharmacy shall be owned by a licensed pharmacist and every drug store shall be owned by a licensed druggist; and no copartnership shall own a pharmacy unless all the partners are licensed pharmacists and no copartnership shall own a drug store unless all the partners are licensed druggists; except that, any corporation, organized and existing under the laws of the state of New York or of any other state of the United States and authorized to do business in the state of New York and empowered by its charter to own and conduct pharmacies or drug stores, and, at the time of the passage of this act, still owns and conducts a registered pharmacy or pharmacies or a registered drug store or drug stores in the state of New York, may continue to own and conduct the same and may establish and own additional pharmacies or drug stores in accordance with the provisions of this article, but any such corporation which shall not continue to own at least one of the pharmacies or drug stores theretofore owned by it or ceases to be actively engaged in the practice of pharmacy, shall not be permitted thereafter to own a pharmacy or a drug store; and except that any person, not a

licensed pharmacist or a licensed druggist, who at the time of the passage of this act owns a registered pharmacy or a registered drug store in the state of New York, may continue to own and conduct the same in accordance with the provisions of this article, and except that the administrator, executor or trustee of the estate of any deceased owner of a registered pharmacy or drug store, or the widow, heirs or next of kin of such deceased owner, may continue to own and conduct such registered pharmacy or drug store, in accordance with the provisions of this article"

Shortly after the decision of the Supreme Court of the United States, the New York State statute was challenged as being unconstitutional Two cases have already come before the lower Courts, in the first of which the statute was held unconstitutional, the Court following the ruling of the Supreme Court of the State of New York In the second case the New York State statute was upheld This second decision is extremely interesting and of great importance

An individual not a licensed pharmacist sought to compel the State Board of Pharmacy to issue to him a certificate of registration of the ownership of a pharmacy, but the Board refused to issue such certificate on the ground that the man was not a licensed pharmacist Resort was then had by this individual to the Court, where the statute was held constitutional It was urged by this man that the decision of the Supreme Court of the United States was authority for the granting of such certificate, but the Court held that each case must stand on its own facts and the record before the Court in this case was sufficient to uphold the constitutionality of the statute In order to understand the reasoning of the Court, it is necessary to quote at some length from the opinion

"The reason for denying to a corporation the right to practice a profession is clearly to prevent the shifting of personal responsibility for inferior quality of personal service Personal ownership and resulting personal responsibility is essential to the safety and health of the public in the practice of any profession For the same reason, it is a reasonable requirement that before a proprietary interest in a pharmacy can be acquired such prospective owner must have become a licensed pharmacist

"The chief function of a pharmacy is to dispense to the public (either compounded under a physician's direction or prescribed by a physician without the necessity of compounding) various drugs and chemicals, the quality of which is an important factor Upon the potency of the drugs and chemicals sold and the quality of the work in compounding them may depend the efficacy of the cure The skill of the physician may be offset by the inferiority of a pharmacist's drugs which have been prescribed It is common knowledge that time is an important element to be considered in the preserving of drugs and chemicals Some become ineffective for a prescribed purpose after they have been permitted to age beyond a certain time, others by chemical change, may be converted into poison In plain speech, public welfare requires that the proprietor of a pharmacy should know his business The health of the public suffers if his stock of drugs is allowed to deteriorate, the safety of the public is endangered if he employs clerks of inferior skill

"No one questions the reasonableness of the statute which requires a practicing physician to be licensed by the state Can it not be said with equal reason that a license should be required of the proprietor of a pharmacy who is responsible for the quality and potency of the drugs and chemicals which the physician prescribes to effect a cure? Is it not reasonable that the state should have some control over the man whose responsibility it is to employ men and women of expert knowledge to compound the prescriptions of a physician? If we license the physician, should we not license him who is largely responsible for putting the physician's advice into effect?

"It is by a statute such as the one under consideration that the state in the interest of public health and welfare can to some measure control the quality of service to be rendered to the sick In effect, the command of the statute is addressed to the owner or proprietor of the pharmacy There the responsibility should remain Possible penal consequences for illegal acts by the proprietors of pharmacies is not enough The demand is for consistent quality of pharmaceutical service Public health means sound health, and it may reasonably require carefully regulated pharmacies to preserve it

"Approaching from another point of view the question of the reasonableness of this statute, the record shows that following the close of the World War illicit traffic in habit-forming drugs and prohibited intoxicants showed a state-wide increase Large profits to those who could legally dispense such products lured persons of inferior character and a low type of mentality into the field of pharmacy Those who sensed the public necessity of high grade pharmacies in communities realized that the profession was being degraded and the effect of its public service handicapped Men of broad knowledge upon the subject, with unquestioned purpose to protect the public, appeared before the Legislature and the governor in support of the act now challenged Their arguments apparently carried conviction It cannot be doubted the Legislature recognized a new evil to be met and prevented 'The needs of successive generations may make restrictions imperative to day which were vain and capricious to the vision of times past'"

The Court then took up the decision of the

Supreme Court of the United States dealing with the Pennsylvania statute and held that it was not conclusive upon the record before him, and the Court then said:

"I return to the question before the Court: Is the statute which the petitioner has challenged reasonably adaptable to and in the interest of public health and general welfare? The answer is supplied by the particular record before the Court in this proceeding, the dominant note of which is the protection of the public. It leads me to the conclusion that the statute does not violate the provision of the constitution which the petitioner invokes. While it may affect his right to pursue his vocation in the way he desires, it does so with authority of law. 'Any trade, calling or occupation may be reasonably regulated if "the general nature of the business is such that unless regulated many persons may be exposed to misfortunes against which the Legislature can properly protect them."'"

It is probable that these apparently conflicting decisions of the lower Courts of the State of New York, one holding the statute unconstitutional and the other holding it constitutional, will be carried to the highest Court of this State and perhaps even to the Supreme Court of the United States. Only in this way can a final determination be had as to the constitutionality of the New York statute.

SUIT FOR PROFESSIONAL SERVICES—MALPRACTICE COUNTERCLAIM

An elderly woman sustained a fall on the sidewalk, injuring her shoulder. A neighborhood doctor was called who examined her and turned her over to a surgeon for hospital care. With the aid of *x*-rays, the surgeon diagnosed the injury to be a fracture of the anatomical neck of the humerus with comminution of the great tuberosity, the parts being completely separated. He reduced the fracture and put her in traction with weights, utilizing the Balkin frame. The patient remained in the hospital about five weeks and then went home with her arm in a brace, her condition having progressed normally. At that time the surgeon turned the care of the patient over to her family doctor. The last time the surgeon saw the woman was a few weeks after her discharge from the hospital when she called at his office to pay him a part of his bill, and at that time she seemed to be in every way satisfied with the treatment she had received.

The surgeon attempted to collect the balance of his bill for professional services and, in so doing, was obliged to institute an action in the Municipal Court to enforce payment. The patient put in a defense that the surgeon had been negligent in his treatment of her, demanding affirmative judgment against him in the sum of $1,000.

When the matter came up in Court before a judge and jury, the attorney for the patient did not attempt to prove any malpractice and withdrew the malpractice counterclaim, but he proceeded with the single defense that the doctor's fee was too great for the services which had been rendered. However, a verdict was found by the jury in favor of the doctor.

ALLEGED INJURIES BY X-RAY MACHINE

A woman about the age of sixty years, as a result of a fall, suffered an impacted fracture of the wrist and her family physician reduced the fracture and applied splints. Subsequent to this treatment the physician, desiring to ascertain whether the reduction was proper, sent the patient to the defendant doctor for the purpose of having an *x*-ray picture taken. The defendant doctor placed the woman's wrist on the table on top of the *x*-ray plate, and proceeded to adjust the *x*-ray machine for the purpose of taking the picture. Very unexpectedly, a steel counterweight supporting the tube and cone carriage which weighed about twenty pounds, snapped and the carriage dropped upon the splints that were around the woman's wrist. She complained at the time that it had jarred her and hurt her but made no particular complaint, and apparently the carriage had dropped so slowly that the splints were not even disturbed.

However, the patient instituted suit against the doctor in charge of the *x*-ray machine, claiming that due to the accident her wrist had never properly healed and that her fingers had become permanently stiffened and that flexion and closure of the fingers had become imperfect to about fifty percent of normal. An examination of the patient by an expert on behalf of the defendant disclosed no condition present in her arm or hand which was not the natural outcome of a fractured wrist in a woman the age of the patient.

When the action came to jury trial the evidence failed to show any injuries traceable to the accident. Judgment was, therefore, directed by the Court in favor of the defendant doctor, dismissing the complaint. An appeal was taken by the plaintiff to the Apellate Division of the Supreme Court but the dismissal of the complaint was sustained, finally terminating the matter in favor of the doctor.

NEWS NOTES

PRINCIPLES OF POPULAR MEDICAL PUBLICITY

The Press Publicity Committee, whose appointment and personnel were announced in this Journal of November 1, page 1344, met on November 10 in the New York Academy of Medicine, and elected Dr. Alec N. Thomson, of Kings County, as Secretary.

The Committee designated one of the two representatives from each District Branch to be Chairman of a Branch sub-committee. An immediate duty of this chairman is to get in touch with each County Society in his District, and secure the appointment of a member to represent the County Society on the District sub-committee.

The Committee adopted the following principles regarding the methods of its procedure and the standards for giving out popular medical publicity by physicians:

"The medical profession in the State of New York, as represented by the Press Publicity Committee of the Medical Society of the State of New York, is keenly aware of the desirability of providing the press with authentic medical news and placing the views of the organized profession before the public. The interests of public health education frequently demand that individual physicians broadcast over the radio on medical topics or write for lay magazines or newspapers. On the other hand, it is necessary that copy of this type adhere to the highest standards and that the self-advertisement of quacks, faddists and irregular practitioners be curtailed as far as possible. The following regulations have been formulated to assure the press of a regular supply of authentic medical news and to protect the public against publicity seekers in the profession and charlatans without.

"1. Requests received by individual members for expressions of opinions on medical matters by newspapers or reporters shall be referred to the Chairman of the Branch Sub-committee of the Press Publicity Committee of the Medical Society of the State of New York of the district to which he belongs. Preferably such information shall be given to the press in the name of the Press Publicity Committee of the Medical Society of the State of New York. When this is impossible, the phrase, 'Dr. So-and-So, speaking for the Press Publicity Committee of the Medical Society of the State of New York,' should be used.

"II. Any State Society member who, by invitation or upon his own initiative, writes an article on a medical topic for publication in the lay press or to be broadcast over the radio, shall submit the said article to the branch sub-committee of this Committee prior to publishing or broadcasting it.

"III. No State Society member shall broadcast an article over the radio, or issue it directly or indirectly to a lay publication, without the approval of this Committee.

"IV. Any State Society member who publishes an article on a scientific subject in the lay press or broadcasts it over the radio shall use *only one title* in conjunction with his name to establish his authority to speak on the topic in question.

"V. Any officer or chairman of a committee of the Medical Society of the State of New York who writes an article in the lay press or delivers a speech over the radio on an extra-scientific subject shall use *only the title of his office* and not any of his personal titles.

"VI. This Committee will approve all authentic scientific articles which are not of a self-aggrandizing nature.

"VII. To guide physicians who desire to write articles for lay consumption, the following definitions are submitted:

"A. *Permissible medical publicity* is the issuance of a public report concerning an event of general interest or importance. It stresses the happening rather than the individual.

"B. *Undesirable medical publicity* is the publication of individual activities designed to magnify the importance of that individual in the eyes of the public.

"C. *Propaganda* is a systematic effort to gain public support for public health activities.

"D. *Public health education* is the impartial instruction of the public in facts related to the prevention and treatment of disease. It stresses the facts rather than the individual presenting them."

The Committee also made the following announcement regarding its activities:

"In formulating the activities of this Committee, we have immediate and remote activities in mind.

"Our immediate activities embrace contacts with the press, with radio stations, and with lecture platforms for the supervision of publicity emanating from the officers and individual members of the Medical Society of the State of New York for public consumption. They include also the preparation and issuance of authentic, up-to-date medical articles and statements of the ideals

of the State Society, to the public press and through the press to the public.

"Our more remote purpose is eventually to establish a liaison with various public health agencies, and in a friendly and cooperative spirit, to supervise the pamphlets, books and other publicity material which they issue to the public so that these may be issued with the approval of the Committee on Press Publicity of the Medical Society of the State of New York."

On November 11 this report was submitted by the Chairman, Dr. Samuel J. Kopetzky, to the Executive Committee of the State Society, which approved it and ordered it published in the Journal, together with an editorial explaining the principles and their application by the District Branches and County Societies.

The Executive Committee also authorized the preparation of reprints of the articles for distribution to the newspapers of the up-State districts under the supervision of the chairmen of the Branch sub-committees.

A. M. A. CONFERENCE OF SECRETARIES AND EDITORS

The Annual Conference of the Secretaries and Editors of the State Medical Society, conducted by the American Medical Association, was held on November 13 and 14, 1931, in the building of the Association at 535 North Dearborn Street, Chicago, Illinois. Those present from New York State were Dr. D. S. Dougherty, Secretary, Dr. O. S. Wightman, Editor-in-Chief, and Dr. Frank Overton, Executive Editor. Sessions were held on Friday morning and afternoon, with a noon luncheon between the two; and on Saturday morning. The Conference chose as its chairman Dr. Earl Whedon, Secretary of Wyoming State Medical Society, who used a loaded five-shooter as a gavel, explaining that the weapon was a badge of authority on his sheep ranch at home, even as a battle mace represents the national dignity and power in the English parliament. Dr. Whedon proved to be a diplomatic presiding officer who judged with promptness and diplomacy.

The speakers included representatives of the American Medical Association: Dr. E. Starr Judd, President; Dr. Edward H. Cary, President-Elect; Dr. Edward B. Heckel, Chairman of the Board of Trustees; and Dr. W. C. Woodward, Chairman of the Committee on Legislation. Then, too, there was Dr. Olin West, Secretary and General Manager, who was the genial representative and mentor of every State Society, giving a clear expression of the attitude of the medical profession toward the subjects discussed by the speakers.

"The Official Records of the Office of a State Secretary" was the subject of a paper by Dr. Emma W. Pope, Secretary of the California State Society. The ideal methods described by Doctor Pope may be found in actual use in the office of the Secretary of the Medical Society of the State of New York.

Dr. C. B. Conklin, Secretary of the Medical Society of the District of Columbia, spoke on some legal points in connection with the practice of medicine by corporations, involving the incorporation of county medical societies for the purpose of contracting to give medical services, as in Iowa. (See the N. Y. JOURNAL, March 15, 1930, page 368.) A corporation is an individual in the eyes of the law, but it cannot attend a medical school or be imprisoned, or make a diagnosis of sickness. A corporation must, therefore, act through hired physicians, thus opening up the question of relative responsibilities of the employer and his agent. While it seems to be a universal principle of all the States that a corporation cannot practice medicine or law, doctors or lawyers may form partnerships in which the members do the actual practice as individuals.

Dr. J. H. Demster, full-time editor of the Journal of the Michigan State Society, spoke of the ideals of an editor of a State Journal in making it a really representative organ of its society and the constituent county societies. Dr. O. S. Wightman, Editor-in-Chief of the NEW YORK STATE JOURNAL OF MEDICINE, spoke of the varied forms of the State Journals, each of which is adapted to its particular State. "The best Journal," he said, "is the one that is read."

"Medical and Hospital Service for Veterans" was the subject of an address by Dr. C. B. Wright, of Minneapolis. Doctor Wright explained that the medical profession was opposed to the bill to give free treatment to all veterans, insisting that the Government limit its action to disabilities incurred in actual service during the war. This attitude had aroused resentment among ex-soldiers, but the veterans were not satisfied with the provision of the United States Government that the patients must go miles away from home and undergo long delays in order to get treatment, some dying of acute appendicitis before they could reach a hospital.

Physicians generally accept the principle of free treatment to all veterans, because it is an established fact; but they advocate the principle that the treatment be given in the patient's own community by the doctor and hospital of his choice. The veterans are accepting

this plan whenever it is explained to them. The speakers suggested that every medical society, from the State to the County, should get in touch with its Legion and explain the advantages of "home" treatment.

Dr. Rollin T. Woodyatt, of Chicago, advocated the use of the hospital and its staff as a practising group, basing his suggestion on his experience in the war, when a group of medical officers at an army camp gave treatment to the people of the town. He also had some experience with a similar group in Chicago. (New York is watching an experiment along this line in Cooperstown, Otsego County. See this Journal, May 15, 1931, pages 642 and 653.)

Dr. A. N. Thomson, of Brooklyn, described the successful coordination of the civic activities of the five County Medical Societies of Greater New York through monthly meetings of their presidents and representatives.

Dr. A. H. Freiberg, of Cincinnati, explained the significance of medical leadership in directing the health activities of agencies of a governmental and civic nature.

The sessions closed with a discussion of medical service in Europe under governmental auspices, by Mr. Nathan Sinai, of Ann Arbor, Michigan. In discussing this paper, Dr. D. S. Dougherty, Secretary of the New York State Society, called attention to the difficulty of separating preconceived attitudes from conclusions reached after actual investigations.

One of the most valuable features of the Annual Conferences is the opportunity to meet the representatives of other States and discuss their mutual problems; but only a limited time is available for these meetings. Possibly the difficulty could be solved by holding an informal evening smoker where the members would feel free to become acquainted.

SECOND DISTRICT BRANCH

The Second District Branch of the Medical Society of the State of New York, comprising Long Island, held a most successful meeting on the afternoon and evening of Thursday, November 19, 1931, in the St. George Hotel, Brooklyn. The President, Dr. L. A. VanKleeck of Manhasset, and the Secretary, Dr. Alec N. Thompson of Brooklyn, had worked long and hard in preparation for the meeting, and the outcome justified their efforts.

The afternoon session was scientific in character and was attended by one hundred physicians. The following program was carried out according to the scheduled time limits:

2:45 p.m. 1. The Polio Epidemic.
- (a) Statement of extent, mortality, etc. Herman T. Peck, M.D.
- (b) Post-polio care from the standpoint of the
  1. Pediatrician: Benjamin Kramer, M.D.
  2. Neurologist: Harold R. Merwarth, M.D.
  3. Orthopedist: Herbert C. Fett, M.D.

3.10 p.m. 2. Pneumonia.
- (a) Types and typing: Max A. Goldzieher, M.D.
- (b) Serum therapy: Thomas A. McGoldrick, M.D.
- (c) Carbogen therapy: John J. Wittmer, M.D.
- (d) Supportive treatment: Henry M. Moses, M.D.

3.35 p.m. 3. Health Examination from the Standpoint of
- (a) Urology: Nathaniel P. Rathbun, M.D.
- (b) Gastro-enterology: Albert F. R. Andresen, M.D.
- (c) Ophthalmology: John N. Evans, M.D.
- (d) Internal Medicine: Simon R. Blatteis, M.D.
- (e) Proctology: Michael Canick, M.D.
- (f) Cardiology: William E. McCollom, M.D.

4.10 p.m. 4. Address on Goiter, with lantern slides: Martin B. Tinker, M.D., Ithaca, N. Y.

These papers were delivered to the editors at once, and will be published in an early issue of this Journal.

The evening session consisted of a banquet which was attended by three hundred guests, and was followed with addresses on the general topic "What about Governmental Medicine?"

Dr. William D. Johnson, President of the Medical Society of the State of New York, made an eloquent protest against the assumption of dictation by government officials and lay organizations.

Dr. Allan J. McLaughlin, Medical Director, United States Public Health Service and formerly Massachusetts Commissioner of Health, told of how the cooperation of family doctors is essential in conducting the work of state departments of health. He explained

that the leadership of health departments lies in fields into which physicians are not prepared to enter; but he advised their withdrawal from the fields as soon as family doctors organize themselves to give service to the public in distinction to private individuals.

Michael M. Davis, Ph.D., Director of Medical Services, Julius Rosenwald Fund, and Member, Executive Committee of the Committee on the Costs of Medical Care, set forth the motives which led governmental bodies and lay organizations to enter the fields of the practice of preventive medicine at a time when physicians were not prepared to undertake the work; but he expressed the willingness of these organizations to leave the fields to the medical profession as soon as the doctors were ready to assume the activities.

Dr. Livingston Farrand, LL.D., President of Cornell University, and Chairman of Governor Roosevelt's Special Health Commission, explained the objects of the Commission and answered objections to the establishment of County Health Departments.

The after-dinner addresses were of entertaining interest, and of great practical value, and will be published in this Journal with the scientific papers which were read at the session held in the afternoon.

GRADUATE FORTNIGHT OF THE NEW YORK ACADEMY OF MEDICINE

The Fourth Annual Graduate Fortnight of The New York Academy of Medicine held during the last two weeks of October attracted physicians from all parts of the United States and Canada. There were more requests for tickets to the afternoon clinics than could be filled. The attendance at the evening meetings taxed the capacity of the large lecture hall.

An outstanding feature was the exhibit. It attracted great interest and was commended by all who saw it. A physician of international prominence expressed himself in regard to it as follows:

"In visiting the rooms of the Academy one could gain more information on the heart than anywhere else in the world. The unprecedented excellence of the material does great honor to the Academy and to the organizers of the Fortnight. I do not believe that so much about an important subject has ever been taught in so short a time. It is something new in the history of medicine."

JOINT COMMITTEE ON GOVERNOR'S HEALTH COMMISSION

This Journal of October first reported the organization meeting of the Joint Committee appointed to consider the recommendations of Governor Roosevelt's Special Health Commission, and also printed the full text of the preliminary report of the Commission in order that the members of county societies throughout the State might take intelligent action in regard to the proposals. An index of information relating to the Commission was printed in the Journal of October 1, page 1200.

The Joint Committee has done an immense amount of investigation, and has held hearings to which it has invited representatives of county societies. Formal hearings were held in four cities as follows:

Buffalo, October 27, attended by 39 representatives from 10 county societies.

Syracuse, November 10, attended by 9 representatives from 7 county societies.

Albany, November 17, attended by 14 representatives from 13 county societies.

New York City, November 24, at which representatives from the Metropolitan District were heard.

Hundreds of sheets of the stenographic reports of the meetings and hearings have been taken, and yet the testimony has been marked with moderation and has shown evidence of thought on the part of representatives of the county societies. The investigation has been conducted by the State Medical Society on a constructive basis.

The next great task of the Joint Committee is to formulate a report, which shall be based on the opinions and facts presented by the representatives of the county societies. This report will then be sent to the Council, and will be forwarded by it to the House of Delegates which will meet in special session some time in December, if possible, to consider the report, and to express the attitude of the Medical Society of the State of New York toward the legislation proposed by the Governor's Special Health Commission.

NASSAU COUNTY

The second regular monthly meeting of the Nassau County Medical Society was held in the Nassau County Bar Association Building in Mineola on the evening of October 27, 1931, with about sixty members present. The President, Benjamin Allison, M.D., presided.

In the business session, an amendment was proposed to create an additional officer in the society, so there will be the President, the President-elect, and the Vice-President. The society was informed of the efforts being expended by the officers of the society to supervise all clinics in the county, and to have none functioning without the approval of the society. A survey is being made to determine how many clinics are in operation and to investigate their natures.

Dr. Van Kleeck, president of the Second District Branch Medical Society, made an earnest appeal for the support of his home medical society in attendance of the dinner and meetmg in the St. George Hotel, Brooklyn, Nov. 19, 1931, the program of which will concentrate on the subject of state medicine. Inasmuch as the Second District Branch has one-fourth of the entire membership of New York State Medical Society, this meeting will be of prime importance.

Thomas H. Russell, M D., Associate Surgeon, Post-Graduate Hospital, New York, spoke on the "Diagnosis and Management of Gastric and Duodenal Ulcers," and exhibited some excellent lantern slides and x-ray films to illustrate cases. He emphasized the importance of the type of pain experienced by the patient, and showed that the cycles were as follows: Gastric Ulcer: (Four Cycles) "Food—Relief—Pain—Relief." Duodenal Ulcer: (Three Cycles) "Pain—Food—Relief." He stressed the finding of tenderness on deep palpation, even after the attack has passed. With the newer knowledge of x-ray and using the extreme Trendelenberg position to secure filling of ulcers in the cardiac end of the stomach, one rarely fails to corroborate the diagnosis. He presented one film of unusual clarity, which showed free gas bubbles in the abdomen, making the diagnosis of perforation.

H. G. WAHLIG, *Secretary.*

BRONX COUNTY

A regular meeting of the Bronx County Medical Society, held at Elsmere Hall, on October 21, 1931, was called to order at 9 P.M., with the President, Dr. Smiley, in the Chair.

The following physicians were elected to membership: Drs. Isidore F. Fishman, Louis J. Goldstein, David O. Gorlin, Meyer Jerome Karsh, Henry Kissel, J. Irving Kushner, Harry Levitt, Paul Luttinger, Charles Schuman, Abraham S. Shatz, Thamara M. Stander, and Mark M. Umansky.

Dr. Smiley reported on a meeting of the Coordinating Committee, and Dr. Archer reported for the Committee on Medical Economics.

The Plan for Medical Relief during the present emergency, which had been proposed by the Presidents of the five County Medical Societies of Greater New York, and which had been approved at a special meeting of the Comitia Minora, was ratified by the Society.

This plan places welfare organizations in charge of the relief. Doctors respond to calls originating in either a welfare organization or a public health nurse or doctor reporting a case of need to the organization. A panel of doctors ready to give medical service is on file with the organization, as is also a table of zones in which the doctors will make calls. The organization agrees to pay the doctor one dollar per visit, with a maximum of twenty dollars per week to be paid to any one doctor. Every physician taking a case agrees to give the patient the necessary amount of treatment regardless of the pay he receives.

The Society adopted resolutions in memory of three deceased members, Drs. Theodore H. Kellogg, William E. Howley, and James F. Kiernan.

The President's inaugural address was given by Dr. Irving Smiley, who summarized his recommendations as follows:

1. To fortify our Society by including every

practicing physician in the Bronx as a member.

2. To endeavor to centralize all public health problems under the guidance of the Society.

3. To provide and maintain a permanent machinery for the continuous cooperation of all factions interested in the health problems of the community.

4. To inject itself into the social, civic and political affairs of the community.

5. To mobilize all the forces possible, necessary to acquire and retain the good-will and confidence of the public.

6. To bring about an effective salesmanship in the marketing of our knowledge, skill, and experience.

7. To inaugurate a plan of consistent and continuous publicity by the courageous use of the press and whatever other means we may deem necessary in order to establish an intimate and cordial relationship with the public.

8. To sell, as it were, the family physician back to the public as the most consistent and enduring factor in all the health problems confronting it.

Following Dr. Smiley, addresses on present day problems in medicine were delivered by Dr. Charles Gordon Heyd, President, Medical Society of the County of New York; Dr. Walter D. Ludlum, President, Medical Society of the County of Kings; Dr. Albert L. Voltz, President, Queens County Medical Society; and Dr. Charles R. Kingsley, Jr., President, Richmond County Medical Society; Dr. Daniel S. Dougherty, Secretary of the Medical Society of the County of New York; and Dr. Alec N. Thompson, of the Medical Society of the County of Kings.

At the conclusion of the program, a vote of thanks was extended to our guests of the evening.

I. J. LANDSMAN, M.D., *Secretary.*

RENSSELAER COUNTY

The Rensselaer County Medical Society met at the Leonard Hospital, Troy, on Tuesday evening, November 10, 1931. The regular business session was delayed, and the scientific session was started first, with a paper by Dr. Helmer P. Howd on "Ruptured Uterus." A case of this sort was cited before the meeting.

Dr. John J. Curley presented a case history of nephrolithiasis with x-ray pictures and a follow-up history.

Dr. Emmott Howd presented a case of osteomyelitis with x-ray pictures and pathological slides.

Dr. Stephen H. Curtis then described and presented a case of diabetes with arteriosclerosis and ulcers of the lower extremities, which was greatly improved by the use of insulin and a high carbohydrate diet.

The business session opened at 10 P. M. with President E. F. Connally in the chair. Dr. C. J. Handron acted as secretary pro tem.

A report from the entertainment committee was given by Dr. Warren W. St. John. He stated that our annual turkey dinner will be held at the Hendrick Hudson Hotel on Wednesday, December 9th, 1931.

Dr. Gabriel Tucker of Philadelphia and Dr. J. B. Harvie of Troy will be the speakers at this annual dinner meeting.

Drs. T. S. A. O'Connor, J. J. Rainey, A. W. Benson, W. W. St. John, C. F. Kivlin and J. H. Flynn were appointed as the medical economics committee.

Dr. J. T. H. Hogan was appointed as representative to attend the hearing on the County Health unit bill.

The names of Drs. F. J. Scott, Charles Lewis, Wm. McDonald, and Frank Davenport were presented as candidates for membership in the society.

Drs. J. H. Flynn, C. F. Kivlin, J. J. Rainey, J. T. H. Hogan, and A. J. Hambrook were appointed as a nominating committee.

After recess they reported a ticket as follows:

Dr. J. B. Burke, for President
Dr. W. W. St. John, for Vice President
Dr. C. J. Handron, for Secretary
Dr. O. F. Kinloch, for Treasurer
Dr. J. H. Bissell and
Dr. C. W. Hamm, for Censors
Dr. A. J. Hambrook, and
Dr. J. H. Reid, for Delegates to the House of Delegates
Dr. J. J. Quinlan and
Dr. F. W. F. Caird, for Alternates

Their report was approved and the meeting adjourned at 11 P. M.

W. B. D. VAN AUKEN, *Reporter.*

SENECA COUNTY

The regular annual meeting of the Seneca County Medical Society was held October 8, 1931, at the Willard State Hospital, Willard, N. Y. There were present fifteen members of the Society, and a number of visiting physicians who were members of the Willard State Hospital Staff.

A business meeting was held at ten o'clock, followed with a dinner given through the courtesy of Dr. R. M. Elliott, Superintendent of the Hospital.

Dr. Donald Guthrie, Sayre, Pa., gave a paper on "The Early Diagnosis and Treatment of Intestinal Obstruction," which was discussed by Dr. William W. Skinner, Geneva, N. Y. Dr. Guthrie divided the cases of acute intestinal obstruction into two types:

1. The simple obstruction, in which there is no interference with the circulation in the gut.

2. The strangulated type. In the treatment, he said, four things were necessary:

1. To relieve the obstruction.
2. To drain the distal intestine.
3. To relieve dehydration.
4. To prevent starvation.

He believes that mortality is considerably reduced by doing a jejeunostomy, in all cases where the condition is unfavorable for radical operation, and in all cases that had been infective ones at the start. In those patients whose condition warrants it, an attack on the obstruction itself was advised. Large quantities of salt solution intravenously, large amounts of 10 to 25 per cent glucose solution intravenously, and by hypodermoclysis, were to be used in the post-operative treatment.

Dr. Homer I. Rexford of Willard, N. Y., gave a mental and neurological clinical demonstration, using about fifteen to twenty patients to illustrate various interesting manifestations of mental derangement and disease. The discussion was well taken up by Dr. Ross E. Herold of Willard, N. Y.

The address of the retiring President was given by Dr. L. W. Bellows, Waterloo, N. Y., on the subject "Ancient and Modern Light Therapy."

F. W. LESTER, M.D., *Secretary.*

TOMPKINS COUNTY

The November meeting of the Tompkins County Medical Society was held on Tuesday evening, the 17th, in the lecture room of the Memorial Hospital, Ithaca, N. Y., with 26 members present, President R. H. Fisher in the Chair.

The Comitia Minora was appointed a committee to nominate officers of the Society for the coming year.

The President appointed the following committee to represent the Society on the Tompkins County Conference of Public Health and Welfare Agencies:

Drs. Homer Genung of Freeville, G. M. Gilchrist of Croton, and Keith Sears of Trumansburg.

The Committee on Public Health submitted its report with reference to the report of the Governor's Special Health Commission as follows:

"Your Committee of Public Health recommends that the Society go on record as favoring, in principle, the report of the Governor's Special Health Commission, as this report is constructive and in accord with the demand for improvement in public health administration

"It also recommends careful study of plans which will be proposed for enacting some of the recommendations of the Commission, and that no approval of the same be given until it can be demonstrated that there is a popular demand for them, and that they meet the approval of the medical profession."

The report was approved unanimously.

The Scientific Session consisted of a paper presented by Emily Dunning Barringer, M.D., of New York City, on the subject of "The Complement Fixation Test for Gonorrhea in Women."

Dr. Barringer is gynecologist in the Kingston Avenue Hospital, Department of Hospitals, of New York City. She presented the results of the work and investigations along these lines made by herself and others which have resulted in making this test more dependable. Several charts were shown. Much interest was shown in the subject as evidenced by the full and interesting discussion. A vote of thanks was given the Doctor and the meeting adjourned.

WILBER G. FISH, *Secretary.*

THE DAILY PRESS

A PSYCHOLOGICAL PROBLEM

Mr. and Mrs.— *One Man's Meat Is Another Man's Poison*

From the *New York Herald Tribune*, October 10, 1931.

HOBBIES AND HEALTH

The New York Times of October 31 extols hobbies and illustrates its thesis with the career of a book collection, as follows:

"One who has a hobby can never tire of life. He always has something of passionate interest. Sometimes the hobby is within the scope of one's vocation. But for the great mass of men it cannot be. In none of the three fundamental types of hobbies (the acquiring of knowledge, the acquiring of things, the creation of things) do the daily tasks give opportunity for self-development or for contributing to the happiness or welfare of others. Most fortunate are they whose vocation allows them the scope and fervor of an avocation.

"Mr. W. K. Bixby, whose obituary appeared in yesterday's *Times,* was one who, having done more than his share of the world's work, found zest in civic service and in cultivating his hobbies. He began with manuscripts, books and paintings. But he was not a bibliotaph—a collector of books and other things of highest human interest, who shuts them away as a miser. He was a lover of the choicest things of the human mind and human skill, and was ever sharing them with others. When the Bibliophile Society many years ago expressed the regard in which he was held by them, they spoke not only of his taste and learning but also of the unselfish generosity with which he placed his 'priceless collections' at the service of his friends.

"His privately printed books include letters of Lamb, a poem of Keats, Robert Burns's 'To Mary in Heaven,' verse and prose by Eugene Field, Andre's Journal and Benjamin Franklin's letter on 'Balloons' in facsimile. By what he did in various fields of letters and the arts, he illustrated 'the energy which cultivates itself.' Incidentally, he made a great circle of life about him, which he enriched by his ardent interest in the best that has come to be in any part of the world, in any age within his reach."

CHOOSING A WIFE

The following editorial in the New York *Herald Tribune* of October 28 discloses a new point of view regarding girls prominent in society affairs:

"The party wallflowers, the girls who are only perfunctorily asked by eligible young men to dance and are then discarded from the ballroom floors; the unhappy maidens who, like the sad clown, must smile while their hearts are breaking, are going to have their innings if Dr. Donald A. Laird, psychologist, has anything to say about it. Wise young men, according to Dr. Laird, will marry the 'dull debutante' and shun the 'peppy party girl' as they would the plague, for the vivacious personality type is due to excessive activity of the thyroid gland, and after five or ten years may become disordered and uninteresting, while her formerly unexciting sister blossoms into the full maturity and charm of an attractive personality.

"If the advice of Dr. Laird were heeded by marriage-conscious youths there would indeed be revolution in our midst. In the sacred white and gold precincts of the Somerset, at the Junior League assemblies, at Saint Cecilia's ball at Charleston and on a thousand less pretentious dance floors, what overturn of the dynasty of wit and charm would result! It would be almost as if the law of gravity were suspended and the prince had inclined a favoring nod not to Cinderella but to her ugly sisters, who will later bloom with all the beauties of Helen.

"Somehow, however, it is doubtful if all this will come to pass. Young love and romance have a way of ignoring the fixed tenets of psychology and eugenics with almost scandalous impunity, and the dread manifestation prophesied by Dr. Laird will induce but few to go on what would amount to a matrimonial diet. It may be hard on the theories of the learned doctor, but beauty and vivacity—ay, even the 'pep' of which he bids us beware—will probably continue to dance blissfully across the ballroom floors of life and toward the altar."

A NEW USE FOR LIP ROUGE

A new use for lipsticks is described in the *New York Times* of October 31, as follows:

"Not long ago restaurant managers were complaining that rosy-lipped ladies ruined napkins by leaving them marked with rouge. Now a lament comes from France that cups and glasses are also stained and spoiled by lipstick. Apparently the modern diner-out hasn't the dainty manners of Chaucer's nun, for when she dined at Southwerk,

Hire over-lippe wyped she so clene,
That in her coppe ther was no ferthyng sene
Of grece, whan she dronken hadde hir draughte.

"The Mayor of Nice has ordered that in all public eating places the table service must be washed after use in water containing a 50 per cent solution of a powerful disinfectant and then rinsed in pure water.

"Yet some hotel-keepers see a positive advantage in lipstick applied to tableware. They say that after a careful washing the rouge lends a high polish to glassware and china. Perhaps the modern cosmetic is, after all, not so very different from the red polishing stuff that always used to be kept in old-fashioned kitchens for scouring pots and pans."

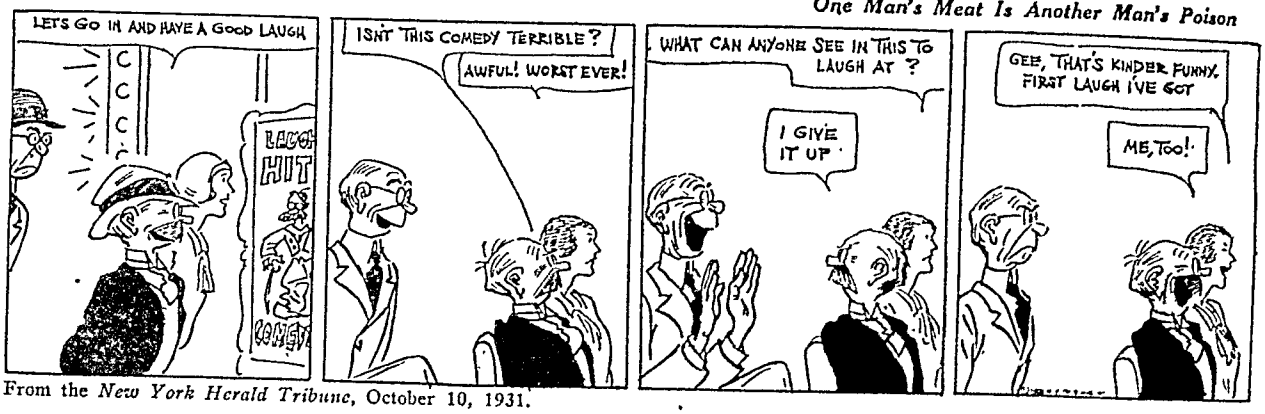
AGE OF MECHANICS

When the French Revolution had freed men from virtual slavery and guaranteed to each person the enjoyment of the products of his own work, philosophers predicted an era of happiness and contentment, for then every person could readily obtain food, clothing, and shelter. But James J. Montague, writing in the New York *Herald Tribune* of October 28, shows the fulfillment of that expectation is still in the far distant future:

When our forefathers wanted to go anwhere
They hitched up the roan or the bay,
Or drove down the pike with a carriage or pair
And made fifty miles in a day.
Today we just back out the automobile,
Give a kick to its slumbering power,
Loll back in the seat with one hand on the wheel
And make the same trip in an hour.

When our ancestors garnered their wheat and their oats
And got in the barley and hay.
And sated with corn the importunate shoats
They toiled eighteen hours a day.

Today they are free from this grueling toil,
Performed in the sweat of the face,
For a small running stream or a few casks of oil
Will do most of the work on the place.



Yet, if our progenitors ever returned
To spend a few days on this sphere,
They would shortly discover how little we've learned
Since the days when they labored down here.
In spite of the wonders that science has done
We still are hard-driven and jaded;
We have no more time, and we have no more fun,
And we have no more pleasures than they did!

THE DAILY PRESS

A PSYCHOLOGICAL PROBLEM

Mr. and Mrs.—

One Man's Meat Is Another Man's Poison

AGE OF MECHANICS

When the French Revolution had freed men from virtual slavery and guaranteed to each person the enjoyment of the products of his own work, philosophers predicted an era of happiness and contentment, for then every person could readily obtain food, clothing, and shelter. But James J. Montague, writing in the New York *Herald Tribune* of October 28, shows the fulfillment of that expectation is still in the far distant future:

When our forefathers wanted to go anwhere
They hitched up the roan or the bay,
Or drove down the pike with a carriage or pair
And made fifty miles in a day.
Today we just back out the automobile,
Give a kick to its slumbering power,
Loll back in the seat with one hand on the wheel
And make the same trip in an hour.

When our ancestors garnered their wheat and their oats
And got in the barley and hay,
And sated with corn the importunate shoats
They toiled eighteen hours a day.

Today they are free from this grueling toil,
Performed in the sweat of the face,
For a small running stream or a few casks of oil
Will do most of the work on the place.

Yet, if our progenitors ever returned
To spend a few days on this sphere,
They would shortly discover how little we've learned
Since the days when they labored down here.
In spite of the wonders that science has done
We still are hard-driven and jaded;
We have no more time, and we have no more fun,
And we have *no more* pleasures than they did!

BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.

PATHOLOGY, BACTERIOLOGY AND APPLIED IMMUNOLOGY FOR NURSES. By ROBERT A. KILDUFFE, A.B., A.M. Octavo of 324 pages, illustrated. Milwaukee, The Bruce Publishing Company, [c.1931]. Cloth, $2.50.

SURGICAL PATHOLOGY OF PROSTATIC OBSTRUCTIONS. By ALEXANDER RANDALL, M.A., M.D. Quarto of 267 pages, illustrated. Baltimore, Williams & Wilkins, 1931. Cloth, $7.00.

THE FOUNDATIONS OF MEDICAL HISTORY. By SIR D'ARCY POWER, K.B.E., F.R.C.S. 12mo of 182 pages, illustrated. Baltimore, Williams & Wilkins, 1931. Cloth, $3.00. (Johns Hopkins University Institute of the History of Medicine.)

MEDICAL CLINICS OF NORTH AMERICA. Vol. 15, No. 2. September, 1931. (Philadelphia Number.) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues): Cloth, $16.00 net; paper, $12.00 net.

THE COMMONER NERVOUS DISEASES for General Practitioners and Students. By FREDERICK J. NATTRASS, M.D., F.R.C.P. Octavo of 218 pages, illustrated. New York, Oxford University Press, 1931. Cloth, $4.00. (Oxford Medical Publications.)

MEDICAL ELECTRICITY FOR STUDENTS. By A. R. I. BROWNE. Third edition. 12mo of 245 pages, illustrated. New York, Oxford University Press, [c.1931]. Cloth, $4.00. (Oxford Medical Publications.)

A COMPENDIUM OF THE STATUTE LAW OF CORONERS AND MEDICAL EXAMINERS IN THE UNITED STATES. By GEORGE H. WEINMANN. Octavo of 240 pages. Washington, The National Research Council, 1931. Paper, $3.00. [Forms Bulletin of the National Research Council No. 83.]

SCHOOL VENTILATION Principles and Practices. Final Contribution of the New York Commission on Ventilation. By C.-E. A. WINSLOW, Chairman, and others. 12mo of 73 pages. New York City, Columbia University Teachers College, 1931. Cloth, $1.00.

A SYSTEM OF BACTERIOLOGY IN RELATION TO MEDICINE. By Various Authors. (Prepared under the direction of the Medical Research Council.) Volume IX. Quarto of 364 pages, illustrated. London, His Majesty's Stationery Office, 1931. Cloth, £8-8-0 a set; £1-1-0 each.

THE PENALTY. Must We Pay It? By DR. ABRAHAM STRACHSTEIN. 12mo of 136 pages, illustrated. New York, Good Health Publishing Co., [c.1931].

HEALTH FOR TRAVELERS. Hygiene and Health Preservation in the Tropics, Orient, and Abroad. By the Staff of the Pacific Institute of Tropical Medicine Within the George Williams Hooper Foundation for Medical Research of the University of California. Edited by ALFRED C. REED, M.D. 12mo of 239 pages. San Francisco, J. W. Stacy, Inc., 1931. Cloth, $3.00.

GYNECOLOGY AND UROLOGY FOR NURSES. By SAMUEL S. ROSENFELD, M.D., F.A.C.S. 12mo of 230 pages, illustrated. New York, William Wood and Company, 1931. Cloth, $2.00.

CANCER AND RACE. A Study of the Incidence of Cancer Among Jews. Conducted under the Auspices of the Jewish Health Organisation of Great Britain. By MAURICE SORSBY, M.D., F.R.C.S.E. Octavo of 120 pages. New York, William Wood and Company, 1931. Cloth, $3.00.

THE NURSE'S MEDICAL LEXICON. For the Use of Graduate and Student Nurses, of Premedical and Dental Students, and of the General Public. By THOMAS LATHROP STEDMAN, A.M., M.D. Octavo of 629 pages. New York, William Wood and Company, 1931. Cloth, $2.00.

A DESCRIPTION OF THE PLANES OF FASCIA OF THE HUMAN BODY with Special Reference to the Fascia of the Abdomen, Pelvis and Perineum. By B. B. GALLAUDET. 12mo of 75 pages, illustrated. New York, Columbia University Press, 1931. Paper, $2.00.

SIMPLIFIED DIABETIC MANAGEMENT. By JOSEPH T. BEARDWOOD, JR., A.B., M.D., and HERBERT T. KELLY, M.D., A.A.C.P. 12mo of 191 pages, illustrated. Philadelphia, J. B. Lippincott Company, [c.1931]. Cloth, $1.50.

SURGICAL PATHOLOGY OF THE DISEASES OF BONES. By ARTHUR E. HERTZLER, M.D. Octavo of 272 pages, illustrated. Philadelphia, J. B. Lippincott Company, [c.1931]. Cloth, $5.00. (Hertzler's Monographs on Surgical Pathology.)

SURGICAL PATHOLOGY OF THE SKIN, FASCIA, MUSCLES, TENDONS, BLOOD AND LYMPH VESSELS. By ARTHUR E. HERTZLER, M.D. Octavo of 301 pages, illustrated. Philadelphia, J. B. Lippincott Company, [c.1931]. Cloth, $5.00. (Hertzler's Monographs on Surgical Pathology.)

ON THE EDGE OF THE PRIMEVAL FOREST. Experiences and Observations of a Doctor in Equatorial Africa. By ALBERT SCHWEITZER, Dr. Med. Translated by C. T. CAMPION, M.A. 12mo of 180 pages, illustrated. New York, The Macmillan Company, 1931. Cloth, $2.00.

INFECTIONS OF THE KIDNEY. By MEREDITH F. CAMPBELL, M.D., F.A.C.S. 12mo of 343 pages, illustrated. New York, Harper & Brothers, 1931. Cloth, $3.00. (Harper's Medical Monographs.)

MIDWIFERY FOR NURSES. By DOUGLAS MILLER, M.D., F.R.C.S. 12mo of 256 pages, illustrated. London, Edward Arnold & Company: New York, Longmans, Green & Company, 1931. Cloth, $2.40.

BOOK REVIEWS

ANNUAL REPRINT OF THE REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR 1930 Cloth Price, $1 00 Pp 91 Chicago American Medical Association, 1931

This book is essentially a record of the negative actions of that distinguished body, the Council on Pharmacy and Chemistry of the American Medical Association, that is, it sets forth the findings concerning medicinal preparations which the Council has voted to be unacceptable for recognition and use by the medical profession Many of the reports record outright rejection or the rescinding of previous acceptances, others report in a preliminary way on products which appear to have promise but are not yet sufficiently tested or controlled to be ready for general use by the profession

Among the reports recording outright rejection are those on Avesan (H), formerly Nuforal, a mixture stated to be composed of formic acid, sodium nucleinate, camphor, allyl sulphide and chlorophyll, with traces of salicin and sulphuric ether, marketed with unwarranted claims of usefulness in the treatment of tuberculosis, asthma, and other respiratory diseases, Ceanothyn once before rejected and still found to be marketed with unsupported therapeutic claims Collosol Calcium and Collosol Kaolin, so called colloidal preparations the former an unscientific mixture of unproved value, the latter a possibly dangerous preparation, and both marketed with unwarranted claims, Ephedrol with Ethylmorphine Hydrochloride, an unscientific ephedrine preparation marketed under an unacceptable proprietary name with unwarranted therapeutic claims, Farastan, an unscientific iodine cinchophen preparation proposed for routine use in 'arthritis and Rheumatoid conditions' Haley's M O Magnesia-Oil, a magnesia magma and liquid petrolatum mixture in fixed proportions marketed with emphasis on the "M O", Lydin a testicular extract, marketed with claims of value in the treatment of impotence, and Metatone, a shot gun tonic mixture marketed under a proprietary name with unwarranted therapeutic claims

THE MODERN HOSPITAL YEAR BOOK The Hospital Reference Book, 10th edition 1930 Quarto of 973 pages, illustrated Chicago, The Modern Hospital Publishing Co, Inc, 1930 Cloth, $2 50

This volume is a useful reference work for all who have to do with hospital construction and administration In addition to the practical and helpful descriptive matter in each section on various phases of hospital planning, management equipment and supplies the book will prove a valuable buyers' guide because of the large and varied lists which it contains of dealers and manufacturers of all types of hospital commodities

Every hospital superintendent and administrative officer will want to keep the annual issues of this hospital equipment encyclopedia within easy reach F

A MANUAL OF TUBERCULOSIS FOR NURSES By D Ashworth Underwood M A B Sc 12mo of 272 pages, illustrated New York, William Wood & Company, 1931 Cloth, $2 50

In this Manual of Tuberculosis for Nurses,' there has been gathered together a most excellent arrangement of information that will repay many a physician and medical student to peruse For its purpose, it could hardly be improved upon, and we most heartily recommend it to all students of tuberculosis whether nurses or not FOSTER MURRAY

THE HAIR, ITS CARE, DISEASES AND TREATMENT By W J O Donovan O B E, M D Octavo of 218 pages, illustrated Philadelphia, P Blakiston's Son & Co, Inc, 1930 Cloth, $3 50

In this book the author has collected all the various diseases affecting the hair ranging from the rarest to the most common He sets forth very interesting examples to illustrate the many conditions as they occur in families, individuals and institutions The book is plentifully illustrated with excellent dermatological photographs The author has simplified the terminology greatly by eliminating many of the synonymous terms and using the subject titles instead His treatment is simple, clear, short and very up to date He has interspersed many prescriptions throughout the book which greatly simplify his explanation of treatment It is a book which should be read with great benefit by the general practitioner and should be perused by the specialist as well G F PRICE

OPERATIVE OBSTETRICS ON THE MANIKIN for students and practitioners By CHARLES B REED M D, F A C S Octavo of 314 pages, illustrated Philadelphia, P Blakiston's Son & Co, Inc, 1931 Cloth, $4 00

The title is somewhat misleading as this book of 309 pages contains much that cannot be taught on or with the manikin

Again we are impressed with the fact that one of the functions of the manikin is to teach palpation, and this has for the most part been left out At the same time, leaving the title as it is, we are impressed with the amount of solid facts embodied in this small volume, and so we can readily subscribe to its value to the student, doctor and teacher

It does furnish many facts and details which in a larger book would have to be sought for, and at times these are carried to the finest minutia, but the various surgical operations that cannot be taught on the manikin we feel should be deleted

In spite of the adverse criticism that has been offered, it is a book that every student, doctor and teacher should have, as it does at all times furnish a very ready and handy authority on this particular subject as well as other obstetrical problems not secured from the manikin G W P

PRACTICAL METHODS IN THE DIAGNOSIS AND TREATMENT OF VENEREAL DISEASES, for Medical Practitioners and Students By DAVID LEES, D S O, M A. Second edition 12mo of 634 pages, illustrated New York, William Wood & Company, 1931. Cloth, $5 00

The book has been and still is in its second edition a compendium of matters pertaining to syphilis and gonorrhea It is written by a venereal logical practitioner for the general practitioner with the intent of guiding the latter as directly as possible Minute indexing, numerous chapter headings, and special treatment summaries allow the busy practitioner to look up some particular therapeutic problem without waste of time or of mental energy The advantages of this type of arrangement are to a certain extent upset by repetitiousness and by artificial splitting of clinical entities The author's counsel seems to be sane and sound throughout, he is conservative in methods of treatment and in standards of cure It is also apparent that his experience is wide and that he has been fairly selective in his recommendations

H L WEHRBEIN.

OUR NEIGHBORS

LAY MEDICAL SERVICE IN MICHIGAN

The Michigan State Medical Society is undertaking an extensive study of the lay organizations dealing with medical services in Michigan. The Council held a meeting on May 19 and listened to explanations of the work of the State Department of Health and four state-wide lay organizations given by representatives of those organizations. (See the New York State Journal of August 15, page 1056.)

The House of Delegates also considered the same subject at its annual meeting on September 22, and a full report of the proceedings are found in the November issue of the Journal of Michigan State Medical Society. The action was based on the following resolution introduced by Dr. A. H. Whitaker of Detroit:

"Inasmuch as there is evidence to show that for some time medical service to the public has not kept pace with medical knowledge, and as during this same period the role of practitioner of medicine has become increasingly difficult;

"And as there is evidence to show that in the United States the practice of medicine is regarded by legislative bodies, by taxation authorities, and by courts of justice, as a business organization with the same responsibilities as other professions, trades and business groups;

"And as also with this change in attitude toward the Medical Profession has come no change in the expectation on the part of the public that the profession will change in its attitude toward the indigent ill, that is, that the burden will be carried by the profession as a group, although there is no other civic responsibility that is not carried by the public in proportion to each individual's economic ability to contribute;

"And as two social and economic changes have recently contributed to the acuteness of the situation, namely,—first, the business depression, which has greatly increased the percentage of the population which is unable to pay for medical care, thus increasing the charity work of the physician, both in his office and in the hospitals and clinics, but at the same time, decreasing the practitioner's income; secondly,—the appearance of numerous organizations of both medical and lay control, which with increasing aggressiveness, are assuming the right to dictate the method of medical service in certain groups;

"And investigation in many counties of Michigan has shown it to be the opinion of the Profession that there is an immediate and critical need for constructive and aggressive leadership in the Profession, to relieve the economic chaos into which the Profession has been thrown, and to assume absolute control of all projects of a medical nature;

"Therefore, respectfully submitting that procedure, which has allowed the development of such economic inefficiency, the development of paternalistic measures almost without opposition; and which has allowed the interference of unqualified groups in the practice of medicine, should be replaced by members sympathetic to efforts at improvement, and willing to be represented by a group of practitioners with full and extraordinary power to study thoroughly these measures, and use executive power to enforce changes endorsed by this House of Delegates as represented by The Council of the Michigan State Medical Society, the following resolution is submitted:

"Whereas, the present economic depression has presented problems which demand immediate study and attention, and

"Whereas, the national government as represented by the President, under whose direction the Public Health Bureau operates, the Medical Corps of the U. S. Army and Navy, and the Veterans' Bureau function, under the control of whom the Narcotic Bureau and Child Health Bureau have been established; as represented by Congress, which by passage of health laws, by licensure laws and by the control of animal experimentation, and as represented by the Supreme Court and its many decisions in medical suits, has imposed certain obligations upon our profession in return for the right to practice medicine, some of which are not only irksome but impose an unfair burden. And as there is, however, no question as to the right of the government to impose reasonable requirements, and there is no tenable position but acquiescence, nevertheless the matter is simplified if the burden is properly distributed, and the reciprocal obligation of the public is established.

"Whereas, the same comments are applicable to local governmental units, which include the following organizations:

"1. The State Department of Health, which is subsidized by the Rockefeller Foundation, the president of which recently stated that food, clothing, posture, sleep, occupation, personnel adjustments, are becoming concerns of public health; which through its County Health Units, combined with other laws, have been given the right by the state to carry on full medical service to the public.

Relative Values of Carbohydrates

New Findings Confirm Old Truths

Recent scientific investigations in rats (tabulated at the right) are in accord with many years of clinical observations on babies, as shown by the following excerpts from authoritative medical literature reflecting the consensus of three decades of pediatric experience

RELATIVE ASSIMILATION VALUES OF VARIOUS CARBOHYDRATES[1]

	Average per 100 gms body weight
1 MALTOSE	1 50
2 DEXTRIN + MALTOSE	1.32
3 Glucose + dextrin	1 32
4 Glucose + sucrose	1 32
5 Glucose	1 04
6 Sucrose + maltose	0 98
7 *Fructose + glucose*	0 98
8 Sucrose + dextrin	0 76
9 Sucrose	0 76
10 Fructose	0 5
11 Glucose + lactose	0 26
12 Lactose	0 16
13 Galactose	0 1

These authors have also stated Maltose fructose glucose starch and dextrin *lead* in nutritive value *followed by* galactose mannose arabinose xylose lactose sucrose and glycogen [2]

Whether it is Atrophic or Hypertrophic Arthritis

THE variety of the disease in rheumatic conditions matters little as far as the treatment is concerned. Pain, loss of function, fever are the manifestations that incapacitate the patient.

ATOPHAN relieves the pain, reduces the congestion and fever, and thereby makes the application of necessary physiotherapeutic measures, such as massage, passive motion, heat, possible.

Neuritis, often a forerunner of rheumatic affections, is promptly relieved by Atophan.

Modern diets often lack minerals

To-day, authorities are stressing the importance of the essential mineral salts. In addition to building sturdy bones, and blood rich in hemoglobin, these mineral elements aid metabolism and contribute to nervous stability.

Yet many modern diets cannot be depended upon to furnish the proper quota of minerals, and therefore millions of people suffer from the effects of demineralization. Cooking destroys a variable amount of the mineral value of foods — in some instances as high as 76 per cent.

To correct this loss and to remedy demineralization — with its attendant symptoms of nerve fag, neurasthenia, lowered vitality and loss of energy—a tonic rich in mineral salts is needed.

Fellows' Syrup contains the mineral salts of sodium, calcium, potassium, manganese, iron and phosphorus, together with the added metabolic stimulants — strychnine and quinine. Sixty years of clinical experience the world over testify to its value as a tonic.

Suggested dosage: A teaspoonful in half a glassful of water three or four times daily.

FELLOWS' SYRUP

instances, provides medical service to a considerable percentage of the population.

"13. The Tuberculosis Division of the Department of Health, which is assuming an increasing number of patients for complete physical examination and extensive *x*-ray examination.

"14. The Cancer Division of the Department of Health, which at the present time is doing no medical work.

"15. Supervision of Sanitation. A medical activity of extreme importance to the public, is entirely out of the hands of the medical profession.

"16. Medical colleges under the supervision of the Boards of Education, which through dispensaries, provide medical care for the public.

"17. The City Hospitals, such as the Receiving Hospital in Detroit, provide medical service for a large number of patients,—many of these cases, if only accident cases are considered, are cases which should be under the direct supervision of the Medical Profession.

"18. City Hospital beds in private hospitals, which provide hospitalization for a section of the public, and the Medical Staffs are providing medical care at no cost to the city, and with no remuneration for the doctors.

"19. The Welfare Departments, which, in many cases regard the group that receives an income which 89 per cent of the population receives as entitled to free medical care, are administering medical service to a large percentage of their communities, often without adequate medical supervision and often in a method destructive to personal initiative.

"Whereas, in addition to the above, the following organizations are encroaching upon the practice of medicine, and it is questionable in so doing if any improvement in medical service is obtained:

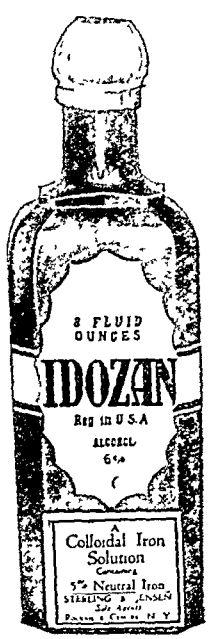
"1. Industrial corporations medical departments.

"2. Private Hospital Clinics.

"3. Privately endowed clinics, and Funds.

"4. Educational Institutions with which are affiliated Fresh Air Schools, Crippled Children's Schools, etc.

"5. Cancer and Heart Clinics.



"6. Army Hospitals.

"7. Marine Hospitals, to which are admitted without cost, all who follow work about the lakes and waterfronts.

"8. U. S. Veterans' Bureau, the activities of which have been expanding rapidly, so they now include medical service for former service men, for conditions which have no connection with their military service.

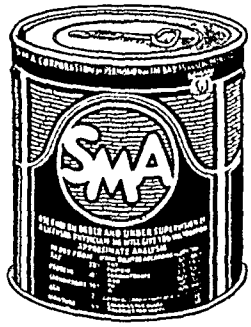
Before the Operation and After

In preparation for the operation  one tablespoonful of Agarol on retiring  in place of the usual castor oil, will insure against gastric upset.  Again, a few days later  when the patient begins to take nourishment  Agarol in half doses  is the logical eliminant because it stimulates peristalsis  gently without griping or pain.



AGAROL is the original mineral oil and agar-agar emulsion with phenolphthalein. It softens the intestinal contents and gently stimulates peristalsis.

Agarol is palatable without artificial flavoring and easy to take. The usual dose in chronic constipation is a tablespoonful, reduced as improvement takes place.

A supply gladly sent for trial.

AGAROL *for Constipation*

"14. Private Clinics, such as the Mayo and the Ford Hospital in Detroit.

"15. Pay Clinics.

"Therefore, be it resolved that this House of Delegates of the Michigan State Medical Society instruct the president that a committee of five members be appointed to study the problems here enumerated, and that this committee be instructed to report in 60 days to the House of Delegates at a special meeting, the results of their study with remedial recommendations; and furthermore that the Council of this Society be instructed to advance the sum of $5,000 to this committee to aid in the work of the committee."

After a lengthy discussion and much arguing, a committee was appointed to investigate the subjects of the resolution, and a formal call was issued in due form, to call a special meeting of the House of Delegates to consider the report of the committee on Dr. Whittaker's resolution.

MEDICAL ORGANIZATION PROBLEMS IN OHIO

The medical leaders of Ohio are considering their responsibilities of medical leadership, as is shown by the leading editorial in the November number of the *Ohio State Medical Journal,* which is as follows:

"During the past year an unusually large number of articles dealing with questions of medical economics have been published in the medical press, and considerable time has been devoted at meetings of medical societies, local, state and national, to a discussion of medical-social and economic problems.

"The fact that so much time and space have been given to discussions of these important questions is ample evidence that the medical profession generally is devoting thought to these issues and that it is not, as frequently charged, trying to dodge its responsibility in correcting whatever maladjustments may exist in present-day medical practice.

"A review of the ideas presented from the various viewpoints reveals that the medical profession realizes that some changes in the present system of medical practice are imminent.

"On the other hand, it is evident that physicians

(*Continued on page* 1487—*Adv. xix*)

(*Continued from page* 1486—*Adv. xviii*)

as individuals have varied and conflicting ideas as to what these changes should be and how they should be brought about.

"We find one group of physicians which believes that no changes whatsoever are necessary and that the present system of medical practice is quite capable of keeping pace with the social and economic evolution which is taking place.

"There is another group which advocates complete socialization of medical service under federal or state control as a panacea for the alleged flaws in the existing system.

"Another school of thought is of the opinion that complete state medicine will not solve the question but that a compromise system, comprising some of the insurance plans employed in Europe, should be worked out.

"Sandwiched in between these three groups are found physicians who have no clear-cut ideas on the matter, and are willing to be converted by the group that presents the most telling arguments.

"This conflict of views and opinions is significant in that it demonstrates the necessity for a better understanding among all physicians of the seriousness and complexity of present-day social-economic questions.

"Furthermore, it emphasizes the need for a stronger and more active medical organization which by the coordination of effort of its component units can bring about an agreement on a program which will preserve the rights of the practicing physician and at the same time adjust the practice of medicine in such a way that it can better meet changing economic and social conditions.

"It becomes clearly evident that the questions before the medical profession today cannot be successfully met by physicians as individuals or by individual effort.

"Through active and united medical organization much progress can be made and varied views and opinions correlated so as to be beneficial both to the medical profession and the public at large."

PELLAGRA STUDY IN SOUTH CAROLINA

The Journal of the South Carolina Medical Association for July contains a report by Dr. C. V. Akin, of the U. S. Public Health Service, on plans for an investigation of pellagra in South Carolina. The following abstract of a letter from

when dyspeptics beg for quick

RELIEF

In functional dyspepsia and gastric neuroses, quick symptomatic relief is afforded by the digestant and sedative Pancreobismuth and Pepsin. And whenever there is insufficient or faulty digestion from any cause, Pancreobismuth will help to supply the needed digestive enzymes.

Pancreatin, pepsin and taka-diastase* provide for digestion of protein, fat and carbohydrate. Bismuth subnitrate allays gastric and intestinal irritation.

Sodium bicarbonate supplies antacid. And powdered ginger is stomachic and carminative.

This tried formula will serve you well for relieving sudden attacks of dyspepsia due to dietary indiscretion and also the more protracted types of gastric or intestinal disorder when the physiological secretions are deficient.

Prescribe ½ to 1 teaspoonful in a wineglassful of lukewarm water after meals.

*Uniform in composition and 2 to 6 times more potent than ordinary malt diastase.

Dr. Akin to the State Board of Health outlines the salient features of the program:

"The Public Health Service has taken the position that pellagra is a diet deficiency disease just as is beri beri.

"While there seems to be some difference of opinion or perhaps I had better say a frank agnosticism regarding the cause of pellagra, it is the general consensus of opinion among the physicians to whom I have talked that the prevention and cure of pellagra is strictly a matter of diet.

"It is my purpose to visit all counties in South Carolina wherein a whole-time health organization is now operating and I hope that it will be possible for you to continue to accompany me on these visits as you have been doing, as your presence serves to identify our study with the general health program of the South Carolina State Board of Health and insures full-hearted cooperation of the local physicians and local authorities.

"As a result of this rapidly undertaken county survey I expect to select, subject to the approval of the State Board of Health, two counties in east central South Carolina and west central South Carolina where an intensive study of pellagra will be undertaken. House to house surveys will be made through which approximately all cases of pellagra will be located. Full information regarding each case will be secured, and effort is being made to identify all factors which might contribute to the cause of the disease in each case. This work will be done in close cooperation with the practising physicians of each county, and no measures will be taken with reference to any case without the approval of the County Medical Association. Once we have established a factor or set of factors which appear to operate constantly in producing the condition we shall attempt through the cooperation of physicians, county health organizations, home demonstration departments and local welfare organizations, where these exist, to build up pellagra control movement which can be operated successfully not only in the counties selected for intensive study, but in any county. The Public Health Service hopes that through their work in South Carolina a course of procedure for controlling pellagra in rural areas will be worked out which can be recommended to any State where this disease is a major problem.

"If pellagra is a diet deficiency disease and if it may be prevented or cured by the regular consumption of such items of food as are suggested by those who sponsor the diet deficiency hypothesis, there seems to be no real reason why the people of this State may not rid themselves of a condition which annually affects some 20,000 to 30,000 persons, and annually kills several hun-

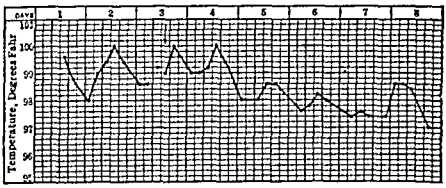
ANALGESIC *and* ANTIPYRETIC ACTION *of the* CHEMICAL TOLYSIN

CASE REPORTS: Acute Rheumatic Fever (III)

IN the avoidance of toxic effects or substantially diminishing such effects, frequently noted where the salicylates are used, the chemical, ethyl ester of para-methylphenylcinchoninic acid (*Tolysin*) holds attractive possibilities for the physician.



Relatively non-toxic and tasteless, it rarely produces nausea or vomiting. With a far greater therapeutic range (1-150 in dogs) than aspirin and cinchophen (1-25 and 1-63 respectively in dogs) it may be administered in larger doses with optimum analgesic and antipyretic effect.

This is a decided advantage in routine practice, well illustrated by the clinical report below (one of a group of thirteen from Am. Jour. M. S. Vol. CLXV, pp. 708–717—reprint on request).

CASE III S. M., male, 49 years, admitted to hospital complaining of pain and swelling in joints. History of recurring attacks of acute rheumatic fever. Present attack began nine weeks previous. Pain first felt in right foot which became swollen, red and tender and remained so for four or five weeks. The joints next involved were right knee, right hip, left wrist, left knee and right wrist.

For first two days in hospital patient was on a sugar tolerance test and received no medication. On third day 2 gm. of Tolysin every two hours, 3 doses, then every four hours; complete relief with subsidence of temperature after receiving 16 gm.; total administered, 38 gm. in five days—no signs of toxicity. Discharged on eighteenth day.

Temperature record of this patient is shown above. Tolysin started at the arrow. Relief from the symptoms coincident with the fall in temperature.

Attention is drawn to the dosage administered and to the *total quantity given in five days, without evidence of* untoward by-effects.

Tolysin's notable analgesic and antipyretic efficiency is attained by proper dosage, as follows: 2 to 3 five-grain tablets as an initial dose *with a glass of water,* repeating in such quantities as to produce a daily dosage of 12 to 20 tablets. After 60 tablets, allow a rest period of several days to one week. For chronic arthritic cases and use in children, suitable reductions may be made.

The chemical Tolysin (ethyl ester of paramethylphenylcinchoninic acid) is one of a group developed by The Calco Chemical Company, Inc. (subsidiary of American Cyanamid Company). Complete chemical literature, including clinical reports, with a generous sample, available to physicians on request.

dred. It is certain that the soil of South Carolina will grow every food which has been suggested as of value in preventing and curing pellagra. The real difficulty, therefore, will be in getting the people who are the most apt to be affected by pellagra, to raise and to eat the foods which are rich in protective elements.

"Occasion will also be taken to study the efficacy of the administration of yeast as is now practised in South Carolina. From the standpoint of administrative efficiency one could scarcely suggest an improvement on the method now employed by the State Board of Health, but the question to be answered is whether or not the yeast as now distributed is actually producing the results which may be expected of it. From my own observations I am certain that not all of the yeast actually purchased by pellagra sufferers is consumed by the case for which it is bought. As the product is not highly appetizing to a great many people, many pellagrains stop taking it before enough has been consumed to benefit the patient even if the yeast had a specific value. It is likewise true that a considerable amount of yeast is ordered by people who do not suffer from pellagra and the product is being taken for a variety of ailments.

"It is expected that the remainder of this year will be spent in studying conditions and it is hoped that before next spring some simple procedure will be developed which can be generally applied and which if followed out will tend to control a disease which is costing South Carolina so much in money and human suffering."

PELLAGRA CLINIC IN SOUTH CAROLINA

The October number of the Journal of the South Carolina Medical Association has the following account of a pellagra clinic held in Oconee County with the cooperation of the doctors of the County:

"The problem of pellagra in Oconee County, South Carolina, is one of considerable magnitude. A Pellagra Clinic was held in the County Health Department on August 12th by Dr. James A. Hayne of the South Carolina Board of Health, and Dr. C. V. Akin of the United States Public Health Service.

"Oconee County is the westernmost tip of the state. A portion of it is mountainous. The land area is 650 square miles, with an altitude ranging from 500 to 2,000 feet, and a population of 33,000 people. The streams are rocky and shallow but furnish a small amount of fish and there is abundant water power. Five cotton mills are operated in the county. The soil is rich and the crops are varied. It produces some of the finest

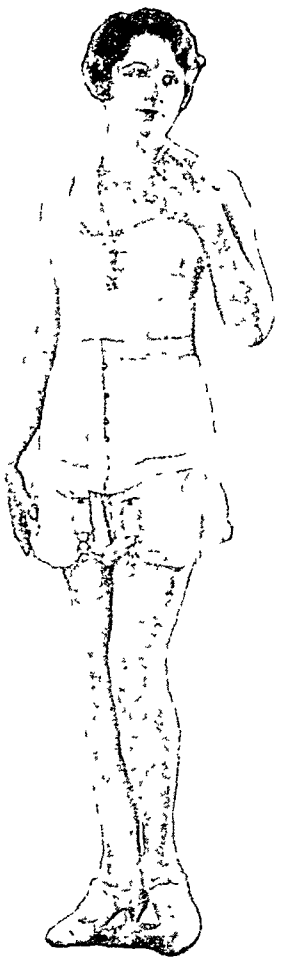
apples in the state The Nantahala National Forest takes in a part of the mountainous section

"Sixty-five pellagrins attended this Clinic, all white except two who were negroes Farm tenants and textile workers made up the larger portion of this number. Pellagra is a countywide disease Grouping these cases according to age, the highest per cent was between the age of thirty and forty years or at the peak of their earning power. The youngest was a child of five years while the oldest was a woman sixty-five



"Among the clinic findings it was ascertained that many of these patients were subject to recurring flare-ups, and the lives of children and adults jeopardized as a direct result of neglect The disease affects one's earning capacity, and economic barriers prevent continuous medical care and supervision time passes and patients expect a little treatment now and then to control the tendency of their disease to grow worse All of these cases had suffered from a few months to several years Some were receiving no treatment whatever, with others treatment was so irregular that it was almost ineffective Those treated by local physicians obtained desirable results for the period of time that they were being treated, but in many cases the doctor was unable to affect a cure because of long intervals between when they slipped away from his care without further treatment or observation, drifting into a state of chronic neglect since they were unable to provide a proper diet or medical treatment, consequently failing to see the results for which they had hoped

"Without this Clinic many patients would not have come under medical supervision and advice at least for a time, nor would they have been followed up and the trend of their disease noted, with the urge that they keep under the observation of their physician until a complete recovery was brought about, neither would they have received educational literature on pellagra nor advice on diet and hygienic living

"Brewster's yeast is sold through our Health Department The increased amount of this yeast advised by local physicians to pellagrins has increased the number of office contacts Most cases take yeast many take it spasmodically or as they can afford it More cases would come to our office if it were not that a grocery store in the county handles brewer's yeast also It is given free through our Health Department to extreme cases of poverty, and sold to all who can pay for it A careful record of every name and ad-

dress of pellagrins contacted is kept in the County Health Department. New and old cases were reached for the Clinic through posters, press publicity, personal interviews, letters, physicians and surveys.

"The cooperative endeavor of the local physicians of the county with this Clinic was manifested through the number of cases that they sent to it.

"Pellagra offers a tremendous field in preventive medicine. It is a problem of economic significance. Serious steps are being taken to prevent its inroads upon the health and efficiency of the people. This is accomplished through education which includes instruction in diet and urging cases to put themselves under the immediate care of their physician, intensive case-finding, and follow-up work.

"The good results of pellagra clinics are sufficiently definite to emphasize an added obligation on the part of the United States Public Health Service in the matter of examining and advising pellagrins. The favorable reaction and response of the people to a Pellagra Clinic have been interestingly demonstrated."

PUBLIC HEALTH LAWS IN NEW JERSEY

The September number of the Journal of the *Medical Society of New Jersey* has the following editorial comment on the public health laws proposed by the doctors of the State:

"The preceding editorial brought to mind an excellent example of a missed opportunity to praise publicly the good deeds of one of our members, and to instruct the laity further regarding such matters.

"About 3 years ago, Dr. Costill, after a period of most praiseworthy service to the state as Director of Public Health, was incontinently thrown out of office; we not only made no protest against using that office as a political football but neglected to express publicly our professional approval and appreciation of his fine work.

"Just recently, another change has been made in the State Department of Health; despite the fact that Director Bowen has proved himself a very capable and efficient officer, he has been disposed of as was his predecessor. In so far as we are aware, no public announcement has been made in either instance by way of explaining these changes. We have no complaint to make regarding the recently appointed Director; for all we know at this moment, he may be an ideal man for the place. But, we dislike the procedure, or method, employed in the making and break-

(*Continued on page* 1493—*Adv. xxv*)

(*Continued from page 1492—Adv. xxiv*)

ing of such an important official as the Director of Public Health in New Jersey.

"During his incumbency of the office, Dr. Costill frequently recommended changes in the existing health laws, and Mr. Bowen, in an address to the State Medical Society at the Annual Meeting in 1930, also set forth the desirability of a fairly complete revision and asked whether the medical profession would join in an effort to procure it Unfortunately, there was no discussion of the symposium of which Bowen's address was a part, and no authoritative answer was ever given to his question. However, at the recent Annual Meeting, provision was made for a special Committee 'to confer with the State Board of Health, and other public health authorities, on Revision of the State's Health Laws.' President Hagerty has named an excellent Committee—chosen with great care—under the chairmanship of Dr William G. Schauffler, of Princeton; and the following additional members: Dr. Joseph C Schapiro, of Union City; Stanley H. Nichols, of Long Branch; Frank C. Johnson, of New Brunswick; and Julius Levy, of Newark. It is hoped that this group will endeavor to bring about several greatly needed improvements.

"The first essential is, of course, to effect such alterations as will best safeguard the health of all residents of the state; i. e., public welfare must be the committee's prime consideration This society long ago constituted itself guardian of the people in all health matters, and it fully intends to maintain that position. In order to meet its obligations it must, however, be given a larger part in the control of health affairs. So, for our committee, that becomes the second important factor in the developments of the proposed conference. At present we have nothing like adequate representation on the Board and, further, we respectfully suggest that it should be a legal requirement that the Director, or Commissioner, must be a physician. We recognize the fact that on occasion the office has been well conducted by a layman, and realize also that some of the best City Health Officers in this state are not doctors of medicine, but such facts have been too greatly dependent upon chance In general, it would probably prove wiser to require that a physician be chosen for head of a state department whose work is so preeminently medical.

REFERENDUM ON MEDICAL CONTROL IN MAINE

The first article in the September number of the *Maine Medical Journal* is an editorial on a referendum to be taken at the general election on sweeping revisions of the several departments of State government. The editorial says:

"By a special referendum on the 9th of Novem-

ber the citizens of Maine are to be given the opportunity of expressing approval or disapproval of the Code Bill recently passed by the State Legislature. This is an important event, and more than that, an interesting and exciting one, for it is history in the making. It is to be hoped that the members of the medical profession will come solidly to the fore and take their rightful place as leaders in endorsing a change which has so direct a bearing on the conduct of health and welfare activities in this state.

"To place responsibility where it belongs in the hands of the man trained to assume that particular responsibility, to avoid waste of resources, time, and energy by centralized control of institutions and departments which from their very nature are united in a single purpose—these are the chief objectives of the code, and let it be said they are the objectives of common sense and all good government.

"During the past year more than one plea has been voiced in more than one state for *'MEDICAL CONTROL OF MEDICAL AFFAIRS.'* The wonder is that the cry has not been louder and more insistent. The long-established practice of constituting lay boards as trustees of public and private institutions with the sole authority to 'hire and fire' hospital directors and employees, and, in like manner, to control the policy and management of these institutions, has proved to be inconsistent with the highest aims of the profession and incapable of rendering the greatest good to the public. By abolishing lay boards of trustees and substituting trained hospital heads appointed by and responsible to a Commissioner of Health and Welfare, the Code Bill takes a long step in the direction of medical control and opens the way for a more harmonious and effective management of state health institutions. In a word, it offers a logical, direct, and dignified means of cooperation between the medical profession of Maine and the state in promoting the health and welfare of her citizens.

"It is clearly stated in the bill just which offices and departments will be abolished and the new appointments that must necessarily be made . . . . . Let every medical man be glad of the opportunity to take a positive stand and prove that doctors are likewise responsible citizens who can and will act in the best interests of their profession, the health and welfare of the public."

The Modern Method of Iodine Administration

Collosol Iodine

(Crookes)

A stable preparation containing iodine 0.2% in combination with protein.

COLLOSOL IODINE has been favorably reported upon in the treatment of rheumatoid arthritis, infective arthritis and allied conditions, in enlarged joints and glands, hypothyroidism and simple goitre as well as in the treatment of obesity from thyroid deficiency. It is indicated wherever internal administration of iodine is necessary.

Advantages Over Other Forms of Iodine

Risk of iodism is minimized. Large quantities may be given with perfect safety.

Elimination is slow with Collosol Iodine. The rapid excretion of iodides diminishes their therapeutic activity.

Collosol Iodine is non-irritant and non-staining when applied to the skin or when used as spray or gargle.

Supplied in ampoules for sterile isotonic solution for intravenous or intramuscular injection and in bottles for oral use.

HOW THE OREGON MEETING WAS RUN

The leading editorial in the November issue of *Northwest Medicine* comments on the Annual meeting of the Oregon State Medical Association as follows:

"An advantage of holding a state medical meeting in a small city is observed in the large attendance at the various sessions, owing to the lack of extraneous attractions. This condition was emphasized at the Eugene meeting last month, October 22-24, as noted in the good attendance during the three days of this meeting.

There were sections on medicine and surgery morning and afternoon for three days, the last period of each morning and afternoon session being devoted to a paper by guests from other states. Thus a total of forty papers was presented at this meeting, making an unusually full program for a state society meeting.

"The reading of papers was not interfered with by the all-absorbing game of golf. The afternoon of the first day was assigned to this sport, the scientific program being held at the same time. Probably the continuous rain interferred to some extent with the activities of the golf enthusiasts.

"The business of the society was transacted with expedition and completeness. The program for each of the three days was initiated by a seven o'clock breakfast, attended by members of the House of Delegates averaging a minimum of fifty members at each sitting. Consideration of business began promptly and occupied every moment until nine o'clock, the time for adjournment to the scientific sessions. This plan afforded abundant time for the full presentation of reports and consideration of all problems which were presented. This program for transacting business of the organization is to be commended to other state organizations.

"The Woman's Auxiliary is an active factor in the life of the Oregon Society."

WEE MODERNS

By BERTON BRALEY

The babies of these present days are raised upon a system,
You count their calories of food and on a card you list 'em;
They're spanked upon a schedule and petted by the clock
And you mustn't ever jounce 'em and you mustn't ever rock;
Physicians choose their style of dress and fix their hours of sleep
And tell you when they ought to laugh and when they ought to weep,
Their every eccentricity is catalogued and filed
For the modern type of baby is a scientific child!

Time was that mother raised them in a rather casual way,
With a bit of help from grandma—but that isn't done today;
The bringing up of babies is a far from simple art
And you need a dozen volumes and a blueprint and a chart,
A clinical thermometer, a stethoscope, a scale,
Some test tubes and a dictaphone that registers each wail,
The modern mother's regimen is very far from mild,
For the baby of the present is a scientific child!

Oh yes, I am describing the *modern* baby now!

Oh, the old folks sniff about it and the jesters jest a lot
But the modern type of baby is a healthy little tot,
He may be robbed of baby-talk, of many pats and kisses,
But there's a heap of colic and other ills he misses;
And in spite of all the sentiment that in our cosmos lurks
There isn't any question that the modern method works—
For the scientific baby is a husky little tad,

FIRST NEED IN DYSMENORRHEA

If one is to have even a fair chance of finding the underlying cause of the trouble, if one is to gain the confidence of the patient, the first need in treating dysmenorrheic women is to relieve the pain. Obviously, if this can be accomplished without the use of narcotics so much the better. For this purpose, one may well turn to Apioline in preference to many of the emenogogic mixtures of uncertain contents and dosage so frequently used. Apioline is a single drug principle derived from apium petroselinum and should not be confused with apiol, the greenish so-called oil of parsley. The dosage of Apioline is definite. One is dealing here with a stable standard product, the effect of which has been demonstrated on uterine muscles and is also evidenced in the increased blood flow to the pelvic region following its administration which makes for equalization of circulation and normalization of flow. It has also been claimed (Laborde and others) that Apioline has a selective action on uterine innervation. Be this as it may, the pain relief which follows its use is often most striking. Samples and literature may be obtained from Laboratoire de Pharmacologie, 92 Beekman Street, New York City. See page xxii.—*Adv.*

A CASE OF TULARÆMIA CONTRACTED IN THE CITY OF NEW YORK

By SAMUEL M. KAUFMAN, M.D., NEW YORK, N. Y.

From the Vanderbilt Clinic and the Department of Dermatology, College of Physicians and Surgeons, Columbia University, New York

SINCE the discovery of the etiology of tularæmia by Francis in 1919,[1] this disease has been recognized and reported from every state except Delaware, Washington and the New England group. Simpson[2] was recently able to collect 800 cases from the United States. Ohara has described the disease in Japan and over 1,000 cases have been reported from Russia. Dr. G. W. McCoy, Director of the Hygienic Laboratory in Washington, to whom serum from the case here reported was sent for diagnosis, informed the writer that this was only the fourth case reported from New York State. For this reason an account of it might be of interest.

Report of Case

M. G., German housewife, was admitted to the Department of Dermatology of the Vanderbilt Clinic, January 26, 1931, with a history of a sore on the left little finger of three weeks' duration. The patient stated that the first week in December, 1930, she procured dressed rabbits from the Washington Market of this city. A few days before the rabbits were prepared she had wounded her left little finger. The woman, however, denied handling either the rabbits or the utensils in which they were cooked, since a friend soaked the rabbits in salt water and cooked them. The friend is entirely well.

About the third week in December the patient developed pains in the elbow joints after finishing a heavy washing. A few days later she developed what she described as a "heavy head cold," complaining of headache, chills and fever. The "head cold" and the pain in the joints persisted for about two weeks and then disappeared. About this time, which was four or five weeks after purchase of the rabbit, the patient noted a small area of soreness about the tip of the left little finger. As the woman had injured this finger while manicuring a few days previously, she felt that she might have "infected it." About the same time the patient noticed a small pimple on the right index finger which she attributed to injury. She thought that a small piece of enamel from her gas range was imbedded in the skin.

After about a week of home medication the condition became worse and the patient then applied to the clinic for treatment. She showed the following lesions:

1. On the volar surface of the tip of the right index finger there was a red infiltrated mass 2x3 cm in area, in the center of which was a sharply circumscribed ulceration about 1 cm in diameter and ½ cm deep. The base showed granulation tissue, the edges were slightly undermined and exuded a greenish gray thick odorless pus.

2. On the dorsal surface of the left little finger, circumscribing the dorsal and lateral half of the nail, was a jagged ulceration of the paronychium about 1.0x0.5 cm surrounded by slight erythema. Except in outline this was similar to the first. Almost no tenderness was present.

3. The epitrochlear lymph glands were markedly swollen, the right measuring 5x2 cm and the left 3x2 cm. The glands were matted hard and slightly tender. The temperature was 99.4.

The axillary nodes were just palpable, the inguinal nodes not enlarged, and physical examination of the chest and abdomen showed no abnormality. The appearance of the lesions corresponded so well to the published descriptions of cases of tularæmia that this seemed the most probable diagnosis. The other possibilities considered were chancre and sporotrichosis. The former seemed unlikely on account of the presence of two lesions, the marked suppuration, the moderate induration and the enormous enlargement of the lymph nodes. The lymph node involvement and the absence of secondary cutaneous lesions made the diagnosis of sporotrichosis unlikely.

Laboratory Findings

The following examinations were made in the laboratory of the Department of Dermatology.

Dark field examination of the ulcers was negative. The blood Wassermann reaction was negative; culture from the ulcers for sporotrichum was negative.

Animal inoculations: A guinea pig was injected January 26 intraperitoneally with 2 cc of defribinated blood from patient mixed with equal volume of salt solution. The animal survived.

Two rabbits and two guinea pigs were injected subcutaneously with ground tissue excised from the border of the ulcer of the little finger. A third guinea pig was inoculated with pus washed from the ulcer. All the animals died in seven to nine days. Upon postmortem examination they showed ulceration of the skin overlying the site of inoculation. The livers and spleens showed innumerable small white flecks. On section sharply bordered foci of necrosis were found scattered through the parenchyma of the involved organs. These areas contained nuclear fragments and scattered lymphocytes; but there was surprisingly little reaction about them; only an occasional epitheloid cell was seen and no giant cells. In smaller and apparently less advanced lesions in the liver, groups of liver cells were found stuffed with basic staining rods and granules. These granules were probably bacteria. Similar invasion of bacteria in epithelial cells in mice has been described by Francis.

An additional rabbit was inoculated subcutaneously with two cc of pus aspirated from the epitrochlear node in the fifth week of the disease. No infection resulted.

The results indicated that the virus was not present at this time in the blood, but was abundant in the tissue and the discharge from the finger ulcer and that the suppurating lymph node became sterile. Cultures made from pus and excised tissue showed only staphylococci. Cultures on Dorset egg and Petroff egg medium from the organs of the infected animals showed some staphylococci and also minute pearly colonies which on smear showed a very small coccobacillus which was Gram negative, as shown in the accompanying photograph.

A culture from an area of subcutaneous infiltration on one rabbit taken by aspiration before death, showed an organism of this same character in pure culture. One strain isolated from a rabbit was tested against the patient's blood serum by Dr. Morales Otero and was agglutinated in a dilution of 1-640.

Agglutination Reactions: Two specimens of patient's blood serum were sent to Dr. G. W. McCoy at the Hygienic Laboratory in Washington and complete agglutination was obtained in the following titres:

	B. Tullarense	B. Abortus
Specimen Jan. 26 (3rd week of disease)....	1-640	1-20
Specimen Feb. 4 (4th week of disease)....	1-1280	1-10

The cross agglutination with B. Abortus is commonly observed. These findings confirmed the diagnosis of tularaemia.

Course of Disease

Wet dressings of 1-10,000 potassium permanganate were applied to the finger ulcers and wet dressings of 1% aluminum acetate to the swollen lymph nodes. Recovery was slow, but uneventful. In three weeks the finger ulcers had healed, but swelling of the lymph nodes persisted. Six weeks after the first observation 2 cc of pus were aspirated from the right epitrochlear node and the swelling subsided somewhat. The nodes have, however, remained enlarged two months after the patient's admission to the clinic.

The accompanying photographs show the condition of patient on February 13 about six weeks after first soreness was noted in finger. The patient's temperature was normal except on the day of admission and she complained of no systemic disturbance.

Source of Infection

The source of infection was difficult to establish. The rabbit purchased in the market might well have been sent from a locality where tularæmia is endemic. The patient, however, denied actually handling the animal. No symptoms were noted for about two weeks later and it is doubtful whether these were due to tularæmia. The sore on the finger, which was probably the primary lesion, was noted after a month. It is doubtful if this history can be relied upon in detail, as the patient became apprehensive after repeated questioning and may well have withheld some essential fact. The virus is known to resist drying for a long period and the hypothesis which seems best to fit the known facts is that she infected herself shortly before the appearance of the ulcer on the finger with some object in her kitchen which had been contaminated by the rabbit several weeks previously. At least this rabbit, purchased in the market, seems the most likely source of her disease.

Description of Disease

The disease now called tularæmia was described by McCoy in 1911[4] as a "plague-like disease of rodents" which he observed in California in ground squirrels in the course of a plague survey. The following year McCoy and Chapin[4] isolated the causative organism, B. Tularense. This organism was first isolated from a human case by Vail, Wherry and Lamb in 1914.[5] A comprehensive description of the disease and understanding of its mode of transmission was first obtained by

Laboratory Findings

The following examinations were made in the laboratory of the Department of Dermatology.

Dark field examination of the ulcers was negative. The blood Wassermann reaction was negative; culture from the ulcers for sporotrichum was negative.

Animal inoculations: A guinea pig was injected January 26 intraperitoneally with 2 cc of defribinated blood from patient mixed with equal volume of salt solution. The animal survived.

Two rabbits and two guinea pigs were injected subcutaneously with ground tissue excised from the border of the ulcer of the little finger. A third guinea pig was inoculated with pus washed from the ulcer. All the animals died in seven to nine days. Upon postmortem examination they showed ulceration of the skin overlying the site of inoculation. The livers and spleens showed innumerable small white flecks. On section sharply bordered foci of necrosis were found scattered through the parenchyma of the involved organs. These areas contained nuclear fragments and scattered lymphocytes; but there was surprisingly little reaction about them; only an occasional epitheloid cell was seen and no giant cells. In smaller and apparently less advanced lesions in the liver, groups of liver cells were found stuffed with basic staining rods and granules. These granules were probably bacteria. Similar invasion of bacteria in epithelial cells in mice has been described by Francis.

An additional rabbit was inoculated subcutaneously with two cc of pus aspirated from the epitrochlear node in the fifth week of the disease. No infection resulted.

The results indicated that the virus was not present at this time in the blood, but was abundant in the tissue and the discharge from the finger ulcer and that the suppurating lymph node became sterile. Cultures made from pus and excised tissue showed only staphylococci. Cultures on Dorset egg and Petroff egg medium from the organs of the infected animals showed some staphylococci and also minute pearly colonies which on smear showed a very small coccobacillus which was Gram negative, as shown in the accompanying photograph.

A culture from an area of subcutaneous infiltration on one rabbit taken by aspiration before death, showed an organism of this same character in pure culture. One strain isolated from a rabbit was tested against the patient's blood serum by Dr. Morales Otero and was agglutinated in a dilution of 1-640.

Agglutination Reactions: Two specimens of patient's blood serum were sent to Dr. G. W. McCoy at the Hygienic Laboratory in Washington and complete agglutination was obtained in the following titres:

	B. Tularense	B. Abortus
Specimen Jan. 26 (3rd week of disease)....	1-640	1-20
Specimen Feb. 4 (4th week of disease)....	1-1280	1-10

The cross agglutination with B. Abortus is commonly observed. These findings confirmed the diagnosis of tularaemia.

Course of Disease

Wet dressings of 1-10,000 potassium permanganate were applied to the finger ulcers and wet dressings of 1% aluminum acetate to the swollen lymph nodes. Recovery was slow, but uneventful. In three weeks the finger ulcers had healed, but swelling of the lymph nodes persisted. Six weeks after the first observation 2 cc of pus were aspirated from the right epitrochlear node and the swelling subsided somewhat. The nodes have, however, remained enlarged two months after the patient's admission to the clinic.

The accompanying photographs show the condition of patient on February 13 about six weeks after first soreness was noted in finger. The patient's temperature was normal except on the day of admission and she complained of no systemic disturbance.

Source of Infection

The source of infection was difficult to establish. The rabbit purchased in the market might well have been sent from a locality where tularæmia is endemic. The patient, however, denied actually handling the animal. No symptoms were noted for about two weeks later and it is doubtful whether these were due to tularæmia. The sore on the finger, which was probably the primary lesion, was noted after a month. It is doubtful if this history can be relied upon in detail, as the patient became apprehensive after repeated questioning and may well have withheld some essential fact. The virus is known to resist drying for a long period and the hypothesis which seems best to fit the known facts is that she infected herself shortly before the appearance of the ulcer on the finger with some object in her kitchen which had been contaminated by the rabbit several weeks previously. At least this rabbit, purchased in the market, seems the most likely source of her disease.

Description of Disease

The disease now called tularæmia was described by McCoy in 1911[3] as a "plague-like disease of rodents" which he observed in California in ground squirrels in the course of a plague survey. The following year McCoy and Chapin[4] isolated the causative organism, B. Tularense. This organism was first isolated from a human case by Vail, Wherry and Lamb in 1914.[5] A comprehensive description of the disease and understanding of its mode of transmission was first obtained by

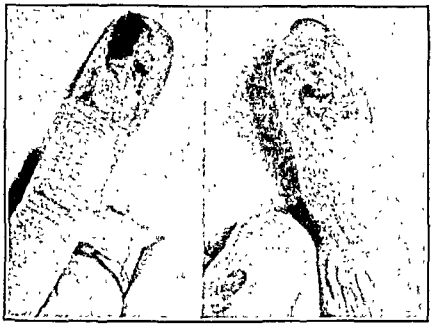

FIGURE 1

Edward Francis in 1919 and 1921.[1] He demonstrated that the disease known in Utah as Deer-fly Fever, and previously described by Pearse,[6] was due to Bacterium tularense, was endemic in rodents and was transmitted to man either by driect contamination from dead rodents or indirectly through insect bites.

Francis emphasized the value of the agglutination reaction in diagnosis and found that this reaction persisted for a long time after recovery. By testing the serum of former cases he was able to show that a case described by Johnson in California in 1904, several cases described by Martin in Arizona in 1907 and subsequent cases appearing in the literature as infections of unknown etiology, were in reality tularæmia. He has also shown that cases reported from Japan[8] and Russia[2] were due to the same infection. The following description of the disease is based largely on the reports of Francis.[1, 8, 9]

FIGURE 2
Forearm showing enormous enlargement of the epitrochlear node.

Tularæmia is a disease caused specifically by Bacterium tularense. The infection occurs as a bacteremia among ground squirrels, wild rabbits, wild rats and wild mice and the water rat or water vole of Russia. The disease may be transmitted secondarily to man in various ways:

1. By the bite of the horse-fly, Chrysops discalis. This species is found chiefly in Utah and the adjoining states, is a blood sucker, preying not only upon cattle, but also upon rabbits and man.

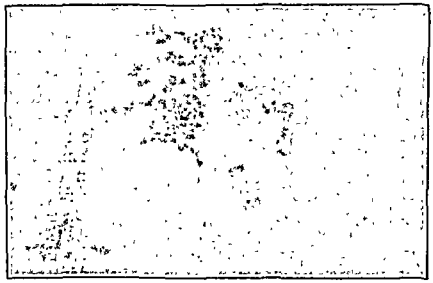

FIGURE 3
B. Tularense culture from infected rabbit.

2. By the bite of the wood-tick, Dermacentor Andersoni. This form is found chiefly in Montana. Its extreme importance lies in the fact that it harbors the organisms in its body throughout

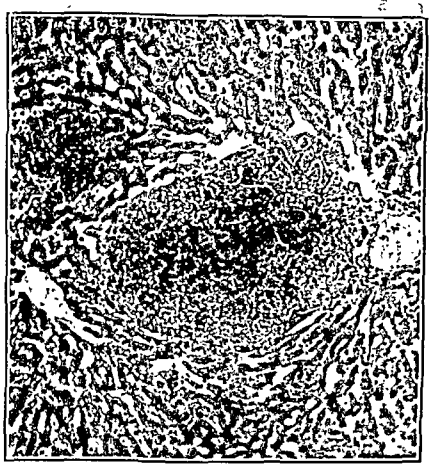

FIGURE 4
Focal necrosis in liver of infected rabbit. x 80 diameters.

Treatment

No preventative vaccine has as yet been developed. The treatment is rest and incision of suppurative glands when necessary. In the particular case recorded above a wet dressing of potassium permanganate seemed satisfactory for the ulcerative lesions. Under no condition is the excision of glands advised.

In conclusion, I wish to express my deep appreciation to Prof. J. Gardner Hopkins for his valuable aid and permission to present this case before you. I also appreciate the assistance received from Drs. Beatrice M. Kesten, Gerald F. Machacek and Miss Rhoda Benham.

POSITION IN PHYSICAL THERAPY*

By K. G. HANSSON, M.D., NEW YORK, N. Y.

PAPERS on physical therapy by very able men often suffer from the attempt of crowding more into them than the average listener can follow and appreciate. This paper will confine itself to a definite, small aspect of the subject and intends to discuss the most favorable position of the part under treatment by physical measures.

Having had most of my experience in orthopedic and traumatic hospitals, I am just trying to pass on what I have learned from bitter experience. It is nothing new but it has not been emphasized in its relation to physical therapeutics. For practical purposes our problem is narrowed down to the question: In what position should we treat a drop wrist, pathology of the deltoid m., the posterior trunk m., the glutteus max. or medius, the extensors of the knee or extensors of the foot, etc., and the reason for these most favorable positions. If the question of position is disregarded in these pathologies, we get deformities induced by either the contraction of the antagonists or by gravity. When we visualize a patient showing all these deformities we will have a body in nearly the same position as that of the fetus, i.e., flexion of the fingers, wrists and elbows; adduction and flexion of the shoulders and the lower extremities show adduction-flexion of the hips; flexion of the knees and feet. Head and trunk show a segment of a circle. This fetal position is approached in many pathologies and we must be on guard to prevent them. It is easier to prevent them than to correct them—once they have developed.

Let us first divide our neuro-muscular system in a concentric group, including all m. producing movements toward the center of the body and an excentric group which includes the m. performing movements away from the body. In general, we may say that the concentric group is antagonistic to the excentric group. This antagonistic action is maintained by a very delicate neuromuscular action that has a practical expression in the m. tonus. This m. tonus maintains a muscular tension which is necessary for the smooth working of our movements. In addition to this antagonistic action we have a synergistic action, i.e., a contraction impulse to a flexor m. is always preceded by a relaxing impulse to its extensor. The workings of this delicate function are not completely understood. A German anatomist in 1910 published his findings of both medullated and non-medullated nerves which ended in different ways among the m. fibers. Modern physiology teaches us that the

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 3, 1931.

striated m have two kinds of fibers the red rich in sarkoplasm and the white ones—rich in fibers The former contract more slowly and prevent too rapid relaxation after contraction Mosso had already in 1904 differentiated between the rapid m twitchings and the more leisurely m tonus This instinsic pattern of a muscle is controlled by both the C N S and the sympathetic nervous system Continuous N impulses are necessary to maintain a normal physiology in a m , both directly on the m fibers and indirectly on the blood supply These N impulses will produce what we call m tonus From experience these impulses produce their optimum effect when the muscle is in mid state, i e , when there is equal muscular tension between flexors and extensors This m tonus is the first thing lost when a muscle is paralyzed and the smooth workings of the unaffected muscles are upset Secondary contractures of these unaffected muscles will produce a shortening of all the soft tissue about the joint involving the connective tissue, the ligaments and the capsule This is what happens on the contracted side On the opposite side we will have overstretching of the muscles and elongation of connective tissue, ligaments and capsule

Von Tilman and Kremer called attention to the fact that over-stretching can produce atrophy Each m has a certain elasticity and Mosso has shown that, after a muscle has been stretched, it will retract but does not return to its original length Till man proved that a muscle can be damaged if by stretching it is prevented from returning to its normal resting position over a certain length of time Such a muscle will soon show deterioration There is a diminution of the primitive striae with gradual disappearance of the striation and, finally, gradual complete disintegration of the m fibers The change of muscle tissue into connective tissue is a consequence of failing functional stimulation and less differentiated tissue takes the place of more highly specialized structures

Even the passing stretching that takes place at rest or when a muscle is spared will produce the same deteriorating effect on the muscle tissue In bedfast patients in late stages the contractures are in positions beyond the rest position It is a well-known fact that such muscles as the extensors of the wrist and fingers, the deltoid m , the gluteı m , the quadriceps and the extensors of the foot and toes atrophy much more rapidly than their antagonists Several reasons for this have been advanced

Comparative physiology will teach us that excentric muscles are relatively younger in their function Concentric movements are older in their function, they have been developed earlier and their structure is therefore stronger and more resistant in every respect We only have to compare the flexors and extensors in the forearm and the adductors and abductors in the shoulder and hip This, we call phylogenesis It is not confined only to the muscular tissues It is undoubtedly true—even of the nerve supply Extensors and abductors are supplied by the nerves from the posterior nerve roots which are branches from the main nerve trunks that seem to continue into the ventral branch supplying the flexors and adductors If this is the reason for the difference in electrical irritability I am not aware of it I have, however, proved to my own satisfaction that less current is necessary to produce a contraction in flexors and adductors than in corresponding extensors and abductors This can easily be done by the Jones condenser set

Mark Jansen suggested that the stronger fascia found in excentric muscles will interfere with the circulation to the muscles when over-stretched It is rational to believe that a continued stretching will diminish the lumen of the blood vessels and produce circulatory changes

Furthermore, the maximum and minimum length of the concentric and excentric muscles indicates that the excentric muscles undergo more physiological stretching than their antagonists

Thus

SUBJECT I	LENGTH IN INCHES

POSITION IN PHYSICAL THERAPY*

By K. G. HANSSON, M.D., NEW YORK, N. Y.

PAPERS on physical therapy by very able men often suffer from the attempt of crowding more into them than the average listener can follow and appreciate. This paper will confine itself to a definite, small aspect of the subject and intends to discuss the most favorable position of the part under treatment by physical measures.

Having had most of my experience in orthopedic and traumatic hospitals, I am just trying to pass on what I have learned from bitter experience. It is nothing new but it has not been emphasized in its relation to physical therapeutics. For practical purposes our problem is narrowed down to the question: In what position should we treat a drop wrist, pathology of the deltoid m., the posterior trunk m., the glutteus max. or medius, the extensors of the knee or extensors of the foot, etc., and the reason for these most favorable positions. If the question of position is disregarded in these pathologies, we get deformities induced by either the contraction of the antagonists or by gravity. When we visualize a patient showing all these deformities we will have a body in nearly the same position as that of the fetus, i.e., flexion of the fingers, wrists and elbows; adduction and flexion of the shoulders and the lower extremities show adduction-flexion of the hips; flexion of the knees and feet. Head and trunk show a segment of a circle. This fetal position is approached in many pathologies and we must be on guard to prevent them. It is easier to prevent them than to correct them—once they have developed.

Let us first divide our neuro-muscular system in a concentric group, including all m. producing movements toward the center of the body and an excentric group which includes the m. performing movements away from the body. In general, we may say that the concentric group is antagonistic to the excentric group. This antagonistic action is maintained by a very delicate neuromuscular action that has a practical expression in the m. tonus. This m. tonus maintains a muscular tension which is necessary for the smooth working of our movements. In addition to this antagonistic action we have a synergistic action, i.e., a contraction impulse to a flexor m. is always preceded by a relaxing impulse to its extensor. The workings of this delicate function are not completely understood. A German anatomist in 1910 published his findings of both medullated and non-medullated nerves which ended in different ways among the m. fibers. Modern physiology teaches us that the

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, N. Y., June 3, 1931.

striated m. have two kinds of fibers: the red rich in sarkoplasm and the white ones—rich in fibers. The former contract more slowly and prevent too rapid relaxation after contraction. Mosso had already in 1904 differentiated between the rapid m. twitchings and the more lesiurely m. tonus. This instrinsic pattern of a muscle is controlled by both the C.N.S. and the sympathetic nervous system. Continuous N. impulses are necessary to maintain a normal physiology in a m., both directly on the m. fibers and indirectly on the blood supply. These N. impulses will produce what we call m. tonus. From experience these impulses produce their optimum effect when the muscle is in mid state, i.e., when there is equal muscular tension between flexors and extensors. This m. tonus is the first thing lost when a muscle is paralyzed and the smooth workings of the unaffected muscles are upset. Secondary contractures of these unaffected muscles will produce a shortening of all the soft tissue about the joint involving the connective tissue, the ligaments and the capsule. This is what happens on the contracted side. On the opposite side we will have overstretching of the muscles and elongation of connective tissue, ligaments and capsule.

Von Tilman and Kremer called attention to the fact that over-stretching can produce atrophy. Each m. has a certain elasticity and Mosso has shown that, after a muscle has been stretched, it will retract but does not return to its original length. Till man proved that a muscle can be damaged if by stretching it is prevented from returning to its normal resting position over a certain length of time. Such a muscle will soon show deterioration. There is a diminution of the primitive striae with gradual disappearance of the striation and, finally, gradual complete disintegration of the m. fibers. The change of muscle tissue into connective tissue is a consequence of failing functional stimulation and less differentiated tissue takes the place of more highly specialized structures.

Even the passing stretching that takes place at rest or when a muscle is spared will produce the same deteriorating effect on the muscle tissue. In bedfast patients in late stages the contractures are in positions beyond the rest position. It is a well-known fact that such muscles as the extensors of the wrist and fingers, the deltoid m., the glutei m., the quadriceps and the extensors of the foot and toes atrophy much more rapidly than their antagonists. Several reasons for this have been advanced.

Comparative physiology will teach us that excentric muscles are relatively younger in their function. Concentric movements are older in their function; they have been developed earlier and their structure is therefore stronger and more resistant in every respect. We only have to compare the flexors and extensors in the forearm and the adductors and abductors in the shoulder and hip. This, we call phylogenesis. It is not confined only to the muscular tissues. It is undoubtedly true—even of the nerve supply. Extensors and abductors are supplied by the nerves from the posterior nerve roots which are branches from the main nerve trunks that seem to continue into the ventral branch supplying the flexors and adductors. If this is the reason for the difference in electrical irritability I am not aware of it. I have, however, proved to my own satisfaction that less current is necessary to produce a contraction in flexors. and adductors than in corresponding extensors and abductors. This can easily be done by the Jones condenser set.

Merk Jansen suggested that the stronger fascia found in excentric muscles will interfere with the circulation to the muscles when over-stretched. It is rational to believe that a continued stretching will diminish the lumen of the blood vessels and produce circulatory changes.

Furthermore, the maximum and minimum length of the concentric and excentric muscles indicates that the excentric muscles undergo more physiological stretching than their antagonists.

Thus:

SUBJECT I	LENGTH IN INCHES			
Muscle	*Normal*	*Min.*	*Max.*	*Diff.*
Deltoid m.	6	4	6,25	2,25
Ext. fingers	18,25	17,25	19,75	2,50
Triceps m.	12	11,50	13,50	2
Erector spines ..	19,50	18	23	5
Glut. max.	10,25	9,75	15	5,25
Quadriceps	18	17,50	19,50	2

Gravity

It is true that gravity exerts most of its effort on the excentric group of mu[illegible]

we have in addition to all the previous disadvantages of this group of muscles the constant pull of gravitation. Therefore, whatever the anatomy and physiology may be of concentric and excentric muscles, the always-present gravity must be considered. A beautiful example of this is in the treatment of facial paralysis. The application of heat, electrical contraction, massage and mirror exercises I believe is only secondary to the support of the muscles innervated by the middle and lower branch of the facial nerve. This can be done by adhesive tape from the corner of the mouth to the ear. Better yet is a padded fishhook which is held by a pincenez holder on the ear.

When we realize that the physical therapy treatment takes less than an hour out of 24 or 48 hours the importance of the position of the relaxed tissue between treatment assumes greater significance.

Drop Wrist

The drop wrist and drop foot are two rather common deformities which we are called on to treat. It is of interest to speculate as to the predisposed nature of the structures involved, especially the musculo-spiral N. and the peroneal N. in particular, the superficial branch of the latter. The toxic properties of alcohol, lead and arsenic seem to select these nerves and the drop wrist often helps in the diagnosis of these poisons. I have been unable to find out any reason for this specific selection and, to say that the phylogenetic age is responsible, is only of academic interest.

In addition to such drop wrist from toxins, we have the paralytic drop wrist, anterior poliomyelitis being the most common pathological cause.

The traumatic peripheral nerve lesion of the musculo-spiral nerve producing a drop wrist is familiar to us all. In this connection I should like to ask you if anyone has had a similar experience as the following: In 1929 I was called in consultation to see a college boy who had received a fracture of his right humerus—middle third. It had been produced during training in hammer throwing. The weight had slipped and landed on this patient's arm fracturing the humerus. He showed clinically complete paralysis of musculo-spiral N. and, three weeks after the accident, he showed a reaction of degeneration. The surgeon, therefore, wanted to do an open reduction and, at the same time inspect the nerve. The consulting neurologist found no disturbance of sensation of the upper extremity and took the responsibility for a closed reduction. This was done and I saw the patient six months afterward with no signs of paralysis and with the fracture healed. It goes to show that we do not know much about the nerve lesions as yet, and it taught me to be more humble in electro diagnosis. This patient had his arm and hand placed in the proper position with wrist and fingers in extension. This position is absolutely necessary when we treat any weakness of extensors of wrist and fingers. The splint should place both the wrist and the fingers in extension while treatment is instituted. The flexors of the wrist and the fingers are very strong compared to the extensors and undergo contraction early.

Epicondylitis

In 1929 I brought out the importance of treating this pathological entity in such a position that the extensors coming off ext. condyle were relaxed for three to four weeks, while undergoing the proper physical therapeutic treatment. Before using the cocked up splint my results were poor; they have been uniformly good since I combined my treatment with the most favorable position.

Shoulder

Of all the muscles in the body the deltoid muscle probably is at the greatest disadvantage, both as to the mechanics, phylogenesis and gravity.

This disadvantage is shown early in life. In Erbs' palsy, it is most important to place the baby's upper extremity in the 90-90 position with the forearm supinated and fingers extended.

To prevent deformities in poliomyelitis, an early abduction splint is necessary to give maximum result in the muscle-reeducation treatment.

In all adult traumatism or disease about the shoulder, we must guard against the loss of abduction. I had once the opportunity of seeing two parallel cases of dislocation of the head of the humerus. One was treated in an abduction splint and was well in six weeks. The other one I treated without a splint and it took him six months—on exactly the same treatment. One fact that I have not seen emphasized in textbooks is the common occurrence of temporary paralysis of the circumflex nerve complicating shoulder dislocations. The abduction of the shoulder in treating fractures about this joint is generally recognized. I believe that it ought to be made a rule in the physical therapy treatment of the shoulder wherever there is the slightest danger of losing the abduction.

Neck

The posterior neck muscle is often the site of occupational or static myositis. This can-

not be treated successfully unless we realize the mechanics of the head and neck

In quadruped animals, the head is held up by the strong ligamentum nuchae and powerful neck muscles In the human biped position, the head is balanced on the cervical spine and the neck muscles act like guy ropes, the ligamentum nuchae being insignificant If we hold our head like a quadruped, as we so often do, in many occupations and also in reading and writing, a great load is carried by the posterior neck muscles giving us the proverbial pain in the neck Such a myositis may be temporarily relieved by heat, massage, static wave current, etc, but the permanent relief will only come with correction of the faulty mechanics We must teach the patient to carry the weight of the head on the spine The spine is for weight-bearing and the muscles are for balance and motion

Shoulder Girdle Brace

The wing scapula is most often part of general poor body mechanics, although we do find it as a single symptom Whether the etiology is anterior poliomyelitis or an expression of pseudo-hypertrophic muscular dystrophy, I do not know The pathology is either a paralysis of the long, thoracic N, or the respiratory N of Bell, or muscular degeneration of the serratus magnus m, the trapezius or rhomboid m The resulting deformity consists in the flaring out of the scapula and a displacement of the scapula laterally away from the posterior spinous processes The conservative treatment of this deformity should include a brace releasing the tension of the above muscles Such a brace consists of a figure eight strap around the shoulders, crossed in the back and connected with a small abdominal strap

Back

No other part of the body suffers so much from treatment and so much from lack of diagnosis as the back and especially the lower back I am not going to burden you with a description of possible pathologies which may produce low back pain Any of the structures of this part of the body may be at fault The skeleton, muscles, nerves, ligaments, abdominal or pelvic organs may be the cause producing symptoms of low back pain I shall, however, emphasize two things that should form the background in our dealings with this complex problem

The first one concerns the evolutionary changes in anatomy and physiology of the lumbo-sacral region In assuming the erect position a 90 degree extension took place between the lower extremities and the trunk Some of this change occurred in the hip joint and some in the lumbar region This anatomical change was not confined to the skeleton but involved all the structures and organs to be found about the pelvis and the abdominal and lumbar region Thereby, a weak structure was prepared for the increased activity that the lumbar spine had to take over A mechanically weakened structure was exposed to an increase in motion Such is the anatomical and physiological background for low back pain

The second point I would like to bring out is the logical sequence of the first one The importance of pain must be realized I believe that pain has a physiological part to play Pain, therefore, although only a symptom, must be respected The sensation of pain is probably the most important help a doctor has in his diagnosis I also believe it is safe to make the following general statement that any pain brought on by overactivity, either qualitatively or quantitatively, should be treated with rest The only complete rest for the back is the recumbent position in the quadruped attitude of spine, hips and knees This can only be accomplished on a hard bed This prevents the sagging under the heaviest part of the body—which is the pelvis and hips The hips are flexed to prevent the pulling of the ilio psoas on the lumbar spine and to relax the quadriceps muscles This position cannot be assumed without flexing the knees If this advice were taken literally, half the population would be spending their time in bed This is not always practical and therefore we must do the next best thing—which is incomplete rest or support For the whole back we use a spinal brace consisting of two steel uprights running parallel to the spine and resting on scapula above and on the pelvis below These steels are the skeletal support of a corset The supporting elastic bands should run parallel to the different muscle layers making up the abdominal wall

The pelvic support consists of a canvas belt placed just below the crest of the ilium, extending from the pubis to just below the umbilicus in front and laced in the back over the sacrum

With such support we will register better result with our physical therapy treatments in these most difficult cases of back pathology —which are probably the most trying patients we have to treat, with the possible exception of our arthritis patients

The Quadriceps

The two muscles in the body which are the most susceptible ones to the atrophy of non

use are the quadriceps and the deltoid muscles. In any pathology of the thigh or about the knee joint, the quadriceps muscle must always be watched because atrophy may set in after a week to ten days. Extension is the most important position in the knee and it therefore becomes necessary to start very early the treatment of the quadriceps to maintain its tone. It is the vastus medius which is responsible for the last few degrees of extension. This muscle is often neglected in the treatment resulting in a wabbly knee and necessitating the locking of the knee in walking. A support is rarely needed because overstretching of the quadriceps seldom occurs and full extension of the knee in standing, walking, sitting or lying is easy to assume.

Drop Foot

As mentioned before, we have in the superficial peroneal nerve or external popliteal nerve a site of predilection for such poisons as alcohol, lead, arsenic, etc.. This produces the well-known drop foot.

I have had the unpleasant task of treating several cases of drop foot due to stretching for sciatic neuritis. This is an example of how paralysis really can result from overstretching of a nerve.

Continuous stretching of the extensor muscles of the ankle and the toes in bedridden patients due to gravity and the weight of the bedclothes is an example of atrophy produced by stretching of the muscles.

In hemiplegia we have a different type of a drop foot. Due to cerebral irritation we have a muscle tonus changed into a muscle spasticity; the flexors getting the better of the pull producing a drop foot. In this connection it is of interest to note how much sooner and how much oftener the lower extremity returns to useful function in a hemiplegia patient compared to the upper extremity. If the demand for function which is forced on the lower extremity in walking is responsible for this recuperation, I do not know. I like to believe so, however, for the sake of those spastic children which we try so hard to save for a useless, joyless and burdensome, longer life.

This drop foot problem always includes a stretching of the extensors of the ankle and toes with accompanying contraction of the flexors of the ankle and toes. When treating these cases, the foot should always be held in 90 degrees to the leg by a brace that relaxes the extensors and stretches or, at least, prevents contraction of the opponents. The application of heat for the nutrition of such atrophying extensors or the contractions of such muscles by means of electrical currents or the muscle reeducation of these same muscles will give better results when the principle of the most favorite position is applied.

The same principle holds in the treatment of a ruptured plantaris muscle. This is not a rare occurrence and is seen in tennis and baseball players. The proper position here is with the foot in flexion—which is accomplished by raising the heel, thereby shortening the plantaris muscle.

Weak Feet

In dealing with the weak abducted foot we have an example of concentric muscles, the tibialis posticus and the tibialis anticus being overstretched and probably undergoing the same changes of atrophy and deterioration. I am speaking of the abducted foot with lowered longitudinal arch. It is only rational to believe that such a change in foot structure as the abduction of the foot, must lengthen or stretch the tibialis posticus and the lowering of the longitudinal arch will do the same thing to the tibialis anticus. The Whitman plate recognizes and therefore corrects both these deformities. The lateral heel spur corrects the abduction and the raised medial part of the plate raises the arch. If we recognize the flat, abducted foot from this point of view and return the tibial muscles to their original normal length, we will be more successful in our physical therapy treatments when they are directed toward improving the circulation or relieving the pain or strengthening the deficient muscles or correcting the body-mechanics.

Conclusions

It is evident that it is easier to prevent deformities than to correct them. In order to prevent deformities, the various parts of the body have a definite, most favored position in which they must be placed. In a general way we must support or prevent overstretching of the muscles performing movements away from the body. We must place an extremity in such a position that the weaker extensors are favored over the stronger flexors, etc.

The effect of gravity on muscle weakness also determines to a certain extent the deformity and must be reckoned with. I believe that many of us have not got the maximum result in our physical therapy treatment because we have had our attention too much centered on the actual treatment and not enough attention has been paid to the physiological pathology underlying our problems.

HUMAN RABIES*

Report of Two Cases

By GUY F CLEGHORN, M D, MINEOLA L I

THE opportunity to examine and observe the uncontrollable symptoms of Human Rabies is indeed slight within the scope of the physician's life journey and I assure you that there is no recompense for the privilege, if it indeed be one, the cases being terrible to the sufferers and horrible to the witness

Rabies is a very old disease, dating back for centuries, occurring in practically all parts of the world but very prevalent in Europe and Asia, with the exceptions of Germany and England where strict muzzling laws are rigidly enforced Outbreaks are constantly occurring in the United States and I would here note that my own County, Nassau, has been under quarantine for three years, on account of its prevalence

Man acquires the disease solely through the bite of an animal, usually a dog but sometimes a wolf, fox, cat, cow, goat or horse Only about 15 per cent of the persons bitten by rabid animals, however, become infected Bites about the face and hands are much more dangerous than bites through the clothing The exact nature of the causative agent has not been determined The Virus is contained chiefly in the nervous system and salivary glands and is conveyed by the saliva, the virus reaching the salivary glands by way of the nervous system and not by the blood stream

The pathology shows that there are marked changes found in cases of rabies in and around the ganglion cells of the cerebro spinal and sympathetic ganglia The ganglion cells are encircled or completely replaced by a collection of round cells The ganglion cells show swelling eccentrically of the nucleus and undergo degeneration This phenomenon of perivascular and perighanglionic cell in filtration gives rise to the so-called Negri bodies or Rabies nodes, the presence of such bodies being generally accepted as characteristic of Rabies

The period of incubation is usually from two weeks to three months, dependent on age, being shorter in children, also the proximity of the part infected to the brain center, the extent and severity of the wound, chances of infection increasing with the number of teeth marks, deep puncture bites being five times as dangerous as superficial ones, open wounds seemingly less apt to admit the Virus

Three stages of the disease are noted in the syndrome (1st) The premonitory stage in which the tissue about the bite becomes irritated, painful and numb, melancholia and depression follow with severe headaches, anorexia, insomnia, irritability, increased sensitivity to light, fear, increase of pulse rates and difficulty in swallowing

(2nd) The stage of great excitement and restlessness with extreme hyperaesthesia develops The slightest stimulus causes violent reflex spasms, particularly to the larynx and mouth These spasms are painful and are accompanied by extreme dyspnoea Attempts to drink water cause insensely painful spasms, so that patient dreads the very sight of water Hence the name of the malady Maniacal symptoms at times accompany the spasms but *the mania is rarely dangerous in form* Temperature usually varies from 100 to 103 and occasionally is normal This stage lasts from one and a half to three days In the interval between spasms, patient may be quiet and the mind unimpaired

The paralytic stage follows that of excitement, the spasms no longer occur, the patient becomes quiet and gradually unconscious, heart action weak and death from syncope results in from four to sixteen hours

Diagnosis in man is usually simple Acute bulbar paralysis may resemble it Tetanus may be confused but in Tetanus the trismus is the initial symptom, the spasms are tonic rather than clonic in character and do not involve especially the muscles of deglutition and respiration and the mental peculiarities of hydrophobia are lacking Pseudohydrophobia develops similar symptoms and the imitation of a barking dog or biting, together with the lack of true respiratory spasm differentiate it

The prognosis, when once the disease is established, is hopeless, palliative treatment is all that can be offered such as chloroform or morphine

Prevention consists of enforcement of muzzling regulations, destruction of strays and quarantining of all dogs imported or transported from localities where rabies is known to exist These methods would stamp out the disease if well enforced

All dog or animal bites should be thoroughly cauterized with fuming Nitric Acid, as cauterization, if properly done, will reduce liability to rabies at least 75 per cent and even if delayed 24 or 48 hours, it has definite value

The Pasteur treatment introduced over forty years ago by Louis Pasteur should be

* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse N Y June 2 1931

given to every person known or suspected of having been bitten by a rabid dog. The Semple method is the treatment now most popular in use and is the carbolized antigen diluted with Saline solution given in daily doses for a period of 21 days.

Two cases came under my observation in May, 1930. Six people, four small children and two adults were attacked by a rabid dog. The children were severly bitten on the face and arms and hands. The wounds were cauterized after a short period with carbolic acid and mercurochrome in four cases, one with Nitrate of Silver and one with fuming Nitric Acid. All received anti-rabic Virus within 48 hours. Two children developed rabies and died.

One, E. S., a boy seven years of age was bitten on the face. He likewise received four slight puncture wounds and three deep puncture wounds on right forearm. The wounds were said to have been cauterized within one-half hour with carbolic acid and mercurochrome. Anti-rabic serum, Semple method, was supplied by the New York City Health Department and given 48 hours after the injury and daily doses for thirteen days. Death occurred on the fourteenth day after the institution of the treatment. Patient was a well built, rugged and healthy boy, and bore the inoculations well until about the tenth when he appeared to be listless, whining and complained of pain in his right forearm over the site of the injury and headache. Examination showed wounds reddened and puffy. Upon inquiry it was found that he had refused food from the night previous. These symptoms became more intense on the next day when patient developed a temperature of 103, very restless, generally refusing food and whining continuously. Bowels obstinately constipated, urine decreased, heart action and respiration accelerated.

Spasms of the muscles of deglutition appeared on the following day and were of short duration but it was impossible to approach him with any sort of food or liquids without forcing them. Irritability and restlessness were very pronounced alternating with periods of quietness and apparent sleep. Extreme dyspepsia at times. A lumbar puncture was performed at this time and was attended by a tremendous amount of physical effort on the part of the patient following which the child gradually became quiet, exhausted with apparent paralytic condition in which he remained until death eighteen hours later.

The second case was typical of the first with the exception that the disease did not manifest itself until twenty inoculations had been administered or the twenty-second day after being bitten and ran a shorter course of only forty-eight hours duration, due probably to the fact that she was a child four years of age, weak and undersized. The spinal taps in these cases were negative.

In conclusion I would strongly advise thorough cauterization of all dog bites with fuming Nitric Acid, anti-rabic Virus in all known or suspected cases and particularly no relaxation of any police or sanitary regulations which tend to localize, control or prevent outbreaks of this disease.

Annual meeting, Hotel Statler, Buffalo, May 23-25, 1932

SPECIAL MEETING OF THE HOUSE OF DELEGATES

The Council of the Medical Society of the State of New York, assembled on December 10, 1931, decided to call a special meeting of the House of Delegates on Thursday, January 14, 1932, in Albany, to consider the report of the Joint Committee on the Governor's Health Commission, and to express the attitude of the State Society toward the legislative recommendations of the Commission. This action of the Council was taken in accordance with a vote of the House of Delegates at its annual meeting on June 1, 1931, as recorded in the Minutes of the House on pages 826 to 828 of the NEW YORK STATE JOURNAL OF MEDICINE of July 1, 1931.

The report of the Joint Committee will be made available to every County Society before the meeting. The full text of the report of the Governor's Health Committee issued last Spring was printed in this Journal of October 1, 1931, page 1208.

MEDICAL SERVICE TO THE UNEMPLOYED

Relief to the unemployed is receiving the attention of official and civic bodies, from the United States Government to the townships and local churches; and organizations and committees are being formed everywhere to distribute the relief to the satisfaction of both those donating and those receiving the relief.

Sickness is first on the list of conditions for which relief is needed. Sickness always arouses sympathy even though it be among criminals and other enemies of society. The physician is therefore the first citizen who is expected to give relief,—and he is always ready to respond to every call of real need. But in estimating the service to be demanded of a physician, two fundamental principles must be considered:

1. The duty of making contributions for relief purposes falls on the doctor as a citizen to exactly the same extent that it falls on all other citizens. In these modern days, the general form of relief is that of financial donations. A doctor is ready to subscribe his proper quota of money for the support of relief agencies, such as the Red Cross, hospitals, church funds, and welfare associations.

2. A doctor is also under an obligation to donate the special service in which he is peculiarly skilled,—that is, his medical service. To treat the poor and the helpless has always been recognized as a commonplace duty by every doctor; and he does not deserve the special credit for offering to treat the needy in these times of unemployment and financial depression. He has been donating medical services every day of his professional life, and he will continue to do so in times of prosperity as well as depression.

The obligation of a doctor to contribute his medical service in addition to his general financial donations is the same as that resting on any other skilled person. The music dealer, for example, is ready to loan a piano for a Red Cross meeting, and to transport it to and from the hall, or to tune the piano that happens to be in the meeting room. At first thought, these might be considered to be personal services only, but actually they cost the music dealer money which he could not afford to give if the calls upon him were frequent.

A doctor, too, is under expense when he makes a professional call upon a poor person. His expense is at a minimum when he calls upon the sick person in a well-equipped hospital,—but he at least pays out money for his travelling expenses. His expense of money and time is often considerable when he gives the treatment in the home of the patient. He must then see that arrangements are made for nursing, for medical supplies, for the care of the children, and for informing the friends. If the patient is in a rural town, the doctor will probably have to call up the drug store, the public health nurse, the welfare commissioner, the priest, and possibly half a dozen other persons. He is the relief agent for the whole community, especially at the outset of a sickness; and he does not lose a minute's time in building up the machinery for the relief and setting it in motion. Moreover, he does the same thing over again with his next needy patient.

Acting as the agent for other relief organizations is a very large burden on the doctor even in large cities; and it is almost intolerable in the smaller communities. Yet all this service is classed as medical relief, when a large part of it belongs in the class of charity, or nursing, or social service.

Suppose a village of five thousand people organizes a service for aiding the unemployed. The doctor, the grocer, the jeweller, the music dealer, and every other citizen offers his own peculiar service to the committee. When that committee is confronted with the problem of deciding what personal service to expect from each individual in addition to his financial subscription to the general fund, the members will begin to realize the variety of the contributions rendered by the physician. The particular activity of the committee will be to act as a clearing station for all forms of relief,—charitable, social, and medical. It will maintain a list of the doctors who are willing to give their services free; and it will assign the doctors in accordance with a plan which they may suggest. After the doctor makes his call, he will report the further needs of the patient to the committee, which shall at once give the service which otherwise would be the burden of the doctor alone.

The committee would also be prepared to ask other business men to donate their personal services as needed. If, for example, the doctor prescribes a dressing to be changed every three hours, the committee might have to ask the jeweller to donate his personal services in fixing the clock. Why should not the jeweller donate his expert services just as the doctor donates his? The doctor will be entirely satisfied if each citizen donates his personal service on the same basis that the physician donates his medical service.

Just a word in regard to paying a doctor for his services. Economic and social conditions in a large city are such that the word "Free" means something very different from that in a village. The Bronx County Medical Society.

for example, has developed a plan by which a relief agency shall pay a doctor at the rate of one dollar for a call. It is an accepted fact that a city doctor spends at least one-third of his income on necessary overhead expenses; and so if his fee is ordinarily three dollars, one dollar of that goes for overhead expenses, and two dollars for his personal service. That one dollar paid to a Bronx doctor represents the cash outlay which the doctor spends when he makes the call; and he gives his personal service free. This plan is entirely satisfactory in a large city where relations are impersonal. This form of payment would probably be impractical in a village where the relief agencies have no extension system of book-keeping.

The response of the doctors to the call for relief is creditable to the profession; and the cooperation of the relief agencies is commendable.

THE ANNUAL INDEX

The special object of the New York State Journal of Medicine is to record the essential activities of the Medical Society of the State of New York and its component District Branches and County Societies, in a permanent form which will be available to the members and also to the medical profession and public health workers generally, not only in New York but also in other states.

The Journal recognizes the fact that the medical societies of other states are also taking an active part in all forms of service relating to the curing of sickness and the promotion of health. The Journal, therefore, abtracts the reports of the activities of the medical societies of other states as recorded in their official state journals. The space which the New York State Journal has given to the records of the activities of medical societies of the counties and states is nearly as great as that devoted to scientific articles. These records are the only comprehensive descriptions of these activities.

The Editors and members of the Publication Committee of the New York State Journal of Medicine have put forth special efforts to make the records of medical society activities available by indexing and cross-indexing them in detail in a special index which has covered an average of six pages during the last three years. The special index this year fills seven pages, and is more extensive and complete than ever before, largely because the activities themselves have included an ever-widening field. The index affords a means by which a worker in any department of medical society activities may ascertain what the societies in other places have done, and may therefore profit by the experience of others working in similar lines.

LOOKING BACKWARD

This Journal Twenty-five Years Ago

Medical Examining Boards: The leading editorial in this Journal of December, 1906, is on the subject "A Single Medical Examining Board," to take the place of a triple board which gave examinations in homeopathy and eclecticism. The editor says:

"The homeopath and the eclectic are not peculiar in the essentials of medicine, and, so far as therapeutics is concerned, they differ no more in their actual practice from the regular practitioner than do the regular practitioners among themselves. Homeopathic and eclectic medicine have practically disappeared; still the laws of New York keep alive the delusion that they exist.

"Now we are confronted by the harm of the law which created three separate medical examining boards. Other 'schools' of peculiar therapeutics are demanding the same special privileges which already have been accorded to the two 'schools' now recognized by the State. The same laws, it is insisted, which apply to homeopathy, should apply to osteopathy, provided each complies with the same requirements; and the State can not much longer be made to see it in any other light. When the State recognized one peculiar sect it opened the way to recognize all.

"Before this absurdity has gone any further it should be stopped. There should be a single examining board, whose business it should be to examine into the qualifications to practice the healing art of candidates applying for a license in this State.

"A doctor whom the State recognizes should be simply a doctor. The State should know no eclectics, osteopaths or hydropaths. Therapeutics is but a small part of the science of medicine. It should be the privilege of the licensed doctor to use small doses or large doses, massage or hydrotherapy or whatever he please, provided he be well grounded in the fundamentals of medicine.

"The medical profession must earnestly take hold of the matter, and of its own initiative demand the abolition of the present three-examining boards system and its replacement by a single board of impartial judges of the qualifications to practice the healing art."

MEDICAL PROGRESS

Cancer Metabolism and Inflammation.—The difficulty of influencing malignant tumors, says Ruth Lohmann, writing in the *Klinische Wochenschrift* of September 26, 1931, lies in the fact that if it were possible to withdraw the oxygen from tumor cells within the body they could live by splitting sugar, and if they could be deprived of sugar, they could live by their oxidation of fat and protein. Serum and tissues apparently offer optimal conditions for the metabolism and growth of tumors. The task lying before those who would treat tumors on the basis of cell physiology consists in producing conditions in the body which so far as possible hinder the respiration and splitting of the tumor cells, that is, in providing a milieu in which oxygen, sugar, and bicarbonate are lacking, with a high content in carbonic acid. In order to learn whether the healthy organism has at its disposal any reactions tending to prevent or destroy tumors, or whether such can be started into activity by any kind of treatment, Lohmann undertook to measure the influence exerted by inflammation upon tumor cells, by placing sections of rat sarcoma and human carcinoma in serum and also in inflammatory exudates derived from cantharides vesicles and pleural inflammations in human beings. Comparing the results in these two media, she found that the cells placed in the inflammatory exudates were uniformly destroyed after 6-14 hours, while control cells in normal serum remained unaffected. She thus demonstrated that cancer cells in an inflammatory environment are not capable of living by the oxidation of their fat and protein content, and that they die even when 3 per cent oxygen is added to the exudate for the purpose of reproducing the conditions found in vivo in the milieu of an inflammation. A capacity for inflammation is accordingly a requisite in the organism that is to cope successfully with cancer. Such capacity is to be understood not only with reference to the degree of an inflammation, but also to the sensitivity necessary for the setting up of an inflammatory condition. This sensitivity is a defensive reaction of the entire organism regarded as a unit, and it becomes less with increasing age. In this may be seen a reason why the body is able to restrain a tendency to proliferate in the years when it is most acutely subject to inflammations, and why proliferation meets with less opposition in the later years of life when inflammatory attacks occur with less violence or not at all. The ideal of prevention would thus be to maintain the capacity for inflammation, so that every degenerating cell will as soon as it is formed be destroyed.

Pruritus Ani.—In discussing the variety of pruritus in adults caused by *Enterobius vermicularis,* W. P. Macarthur states that this nematode has been removed from the genus *Oxyuris* for the reason that its characteristics do not conform to those of the genotype *Oxyuris equi.* The ova of Enterobius practically always gain access to the human digestive tract by way of the mouth, and hatch in the duodenum. The larvae migrate to the cecum, where the majority of the worms exist. The gravid females make their way to the rectum and anus to oviposit, and it is their wriggling movement which cause the irritation loosely called pruritus. There is no multiplication of the parasites within the body. Patients often suffer nightly torments from enterobiasis without the cause being suspected. In every case of nocturnal pruritus ani, the presence of this parasite should be suspected, and further examination should be carried out. The most thorough diagnostic measure is a rectal wash-out with three or four ounces of saline, *which must be administered when pruritus is active.* After a few minutes this is returned and examined for worms. As the itching usually ceases before morning, such remission constitutes strong evidence of enterobiasis. The most efficacious treatment consists in the removal by lavage of the adult female worms which have migrated to the rectum. For this purpose nothing is superior to salt water in a strength of two tablespoonfuls of salt to the pint, 4 ounces of the solution being sufficient for the injection. It is useless to give the injection at any time when pruritus is not felt. There is no drug so effective as to make rectal irrigation unnecessary, though 2 grains of santonin, combined with ½ grain of calomel, is distinctly helpful. To avoid autoinfection, which occurs most readily, the patient should wash his hands thoroughly every time after touching the surface of the body or an undergarment, since there is no certainty that eggs have not been picked up.—*British Medical Journal,* August 22, 1931, ii, 3685.

Determination of Blood Bilirubin by Splenic Contracture as a Functional Test in Tuberculous Subjects.—Giovanni de Flora, writing in the *Riforma medica* of August 3, 1931, reports that he examined the blood of 30 tuberculous patients before and after injection of adrenalin, and found an increase of blood sugar after the injection. Next, in order to eliminate the adrenalin factor, and to exert a stimulation as directly as possible upon the spleen, he froze the region around the spleen by spraying it for one minute

with ethyl chloride, in 3 individuals, and then likewise made tests for blood sugar. As is generally known, the blood sugar is very sensitive to the influence of adrenalin; hence the author made simultantous records of the blood sugar and the blood bilirubin, both after adrenalin and after freezing. He found that after freezing the splenic region there was no increase but a definite decrease of blood sugar. He could therefore conclude that the behavior of the blood bilirubin depends not on the adrenalin but on the contraction of the spleen. This conclusion was reinforced by the fact that in two of the cases in which he had performed perfrigeration in corresponding opposite metameres (splenic and hepatic areas), he found in the former very conspicuous modifications of the blood bilirubin curve, and in the latter scarcely any variations. In view of the importance of the spleen as a station of the reticuloendothelial system, and regarding it as an index of the properties of the rest of the system, it is possible to say that these tests may be regarded with approximate accuracy as a functional sounding of this important system. This was confirmed by the clinical behavior of the patients examined, for in all the tuberculous persons in whom the process was benign the bilirubin curve took an ascending course, whereas in those where the disease was grave the reaction was slight or altogether absent. This demonstrates the importance of the reticuloendothelial system for the defense of the body against chronic processes, such as syphilis, leprosy, and especially tuberculosis. From this observation we may deduce that the hypovegetative type is the one most predisposed to tuberculosis, because its mesenchyma is poor and exhibits little activity. As is known, the reticulo-endothelial system is the principal representative of the mesenchymal tissue, hence it is the first to feel the inroads of Koch's bacillus. Its functional sounding is therefore of great importance both for prognosis and for treatment.

Restoration of Thumb Action by the Graft of a Functionally Injured Finger from the Same Hand.—P. Bonnet and F. Carcassonne point out that if an injury has destroyed a thumb and has at the same time rendered a finger of the same hand useless, the transplantation of the latter to replace the thumb is sometimes quite feasible and is greatly to be recommended, in view of the importance of the thumb. The authors have recently succeeded in making such a graft in a workman whose hand was caught in a machine, which cut off the thumb below the second phalanx, and injured the next three fingers seriously. It was possible to utilize the index finger to create a new thumb, and the procedure was accordingly carried out in a 4-stage operation, as follows: (1) Preparation of stump of thumb. (2) Preparation and oblique section of bone of the index finger. (3) Transference of the finger, with retention of a wide internal pedicle. (4) Section of pedicle. Eleven months after operation the result was complete and the condition perfect, except for rigidity. A tendinous graft will be attempted at a later time. Sensitivity is completely restored, and the patient has a useful hand. In such an operation the chief precautions to be observed are: (1) To make sure of perfect viability of the tissues. (2) To avoid making too long a graft, which would be awkward for use as a thumb. Not the entire finger, but the first or first two phalanges should be utilized, according to the length needed. (3) To make sure of rotation of the finger into the plane of the thumb, so that the palmar surface of the index will meet that of the remaining fingers, and thus make a grasp possible. One should also bear in mind the danger of necrosis from too early liberation of the pedicle, or from compression of vessels by a badly applied dressing or too accentuated an angle of the nutritive flap. In the case under consideration, the patient has the use of his natural metacarpo-phalangeal joint, but not of the grafted phalango-phalangeal joint. In rare cases it is possible to restore the usefulness of the latter, but not unless the finger is in perfect condition. A grafted thumb of this kind is not suited for very heavy labor, since it is more fragile than the thicker lever of the first metacarpal, but for ordinary purposes it meets all needs. The operation is especially appropriate in that it conserves for useful ends an injured finger that would otherwise have to be amputated, and makes unnecessary the mutilation involved in the sacrifice of a sound finger for this purpose, such as is often practised.—*Lyon Chirurgical*, September-October, 1931.

Extraordinary Development of the Lower Lobes of the Lungs, without Morbid Involvement, in a Patient Treated by Right Artificial Pneumothorax.—G. Rossel makes a report in the *Schweizerische medizinische Wochenschrift* of August 22, 1931, of what he believes to be a unique case of its kind. In a young man of 24 in whom it was possible to obtain an ideal elective collapse limited to the right upper lobe, by means of pneumothorax continued at intervals of 8-10 days over a period of 2½ years, the two lower lobes, which at first retained their normal dimensions, began, at the end of 21 months, to exhibit an extraordinary progressive development upward in the shape of a cone. Little by little they began to "swell," and, as the months went on, to "hypertrophy" more and more, until finally their upper margin reached the clavicle. When this point was reached, it became very difficult to make the insufflations, as the needle encountered the lung. Since it was evident that they were try-

ing to assume the size of the entire lung and had almost completely filled the pleural cavity, the pneumothorax was stopped, after a total of 98 insufflations. Ten months have elapsed since then, and the patient's restoration to health is complete. The development of the lung is still more accentuated, and as seen in the radiogram, the two lower lobes appear to have taken on the size of the entire lung. The upper lobe is completely retracted against the mediastinum. One who did not know the patient's history would think it was an azygous lobe. Upon auscultation respiration is heard over the entire right hemithorax; it is ample, vesicular, without adventitious bruits, and differs in no way from that of the left lung. Only at the extreme apex is it weak (in the supraclavicular fossa). It is possible that a small pocket of gas still remains there. The possibility of an *elective pneumothorax,* which is relatively little known, is based on the tendency of the pulmonary tissue infiltrated by tuberculosis to retract, while the sound tissue is unaffected. Assuming that there are no pleural adhesions, the result of small and frequent doses of pneumothorax is not to compress, but to promote retraction; the aim of the insufflations will be to follow the retraction, and support it. It is impossible to say whether the astonishing development of the two lower right lobes is due to a simple compensatory emphysema or to a veritable hypertrophy with new growth, for nobody knows whether there is such a thing as new growth of pulmonary tissue, be it hypertrophic or reparative.

Epidemic Meningitis Minor.—During the period from February 21st to April 8th of this year J. V. C. Braithwaite and W. Mitchell Innes observed 13 children suffering with symptoms of meningitis at the Leicester Royal Infirmary. They presented a clinical picture similar to that described by Quincke, in 1893, under the name "serous meningitis," but with some important differences. Eight of the cases in the series were secondary to bronchopneumonia, usually of a mild type. The onset was sudden in seven, insidious in six. Vomiting, headache, and drowsiness were the most constant symptoms. Nuchal rigidity was present in all of the patients, while 11 of them had a positive Kernig sign. The cerebrospinal fluid was under pressure, clear and sterile. The protein tended to increase slightly, but usually there was no other abnormality. Lumbar or cisternal puncture caused rapid and complete disappearance of the symptoms, usually after one operation, and there were no fatalities. At the same time as the occurrence of these cases there was a mild epidemic of cerebrospinal fever and also an influenza epidemic. The condition might, therefore, have been an abortive form of either influenzal or cerebrospinal meningitis, probably the former. The disease differed from Quincke's serous meningitis in that the age of the patients ranged from nine months to six years, while Quincke states that serous meningitis is mainly a disease of young adults. Other points of difference were: the shortness of the course in the cases under consideration, while Quincke's cases lasted from four weeks to five months; otitis media was absent in the authors' cases, while in Quincke's cases it was frequently a point of origin; fatal cases were common, according to Quincke, and he found an occasional growth of microorganisms from the cerebrospinal fluid. He also noted tetany as a complication. The authors suggest that, in view of the benign course of the disease in their series of cases, the name "meningitis minor" is preferable to "serous meningitis."—*British Medical Journal,* September 26, 1931, ii, 3690.

The Mechanism and Pathogenesis of Alternation of the Pulse.—On the basis of a case personally observed, a new explanation of the mechanism of alternation of the pulse is put forward by N. Kisthenios and M. Gomex in the *Archives des maladies du coeur et des vaisseaux* of July, 1931. In the normal state the left ventricle, before driving into the aorta the mass of blood it contains, increases the intraventricular pressure in the first phase of its contraction until it is greater than that in the aorta at the moment. This may be called the presphygmic phase, because it produces no sphygmographic phenomenon. During this phase the heart expends only a portion of the energy at its disposal, reserving the remainder for the second phase, that of evacuation of the blood into the arterial system. But when necessary, the normal heart may produce a complete systole, stronger by reason of the reserve force which it does not ordinarily utilize, but which enables it to produce a greater amount of energy when this is demanded. It is quite evident that the duration of the two successive phases of the cardiac contraction, and the energy that the heart must employ in the course of each, will be a function of the peripheral resistance and of the pressure which dominates the arterial system during diastole; if these are augmented, the heart, compelled to expend an inordinate amount of energy while it is making tension of the ventricle, will have to call upon its reserve forces to assure complete evacuation of the blood. If these forces are exhausted, evacuation will be incomplete. The authors believe that in cases of alternation, elevation of diastolic pressure and exhaustion of the heart are present at the same time. The increase of diastolic pressure, because of peripheral resistance, has the effect of prolonging the phase of ventricular tension, and of exacting of the heart a great expenditure of energy during this period, so that the organ is incapable of calling on its reserve forces owing

to exhaustion. It follows that the ventricle will evacuate the blood only incompletely into the vessels; hence the pulse will be feeble. The next time, however, in view of the small amount of blood which has entered the arterial system, the peripheral resistance will be less, the first phase of systole brief, the effort to open the sigmoid valves less, the evacuation of blood complete; hence there will be a strong pulsation which will in its turn increase diastolic tension, and so on.

The Diagnostic Program in Food Allergy.—Warren T. Vaughn states that a realization of the deficiencies of the skin test, which is only 50 per cent accurate in the detection of food allergy, has led to the diagnostic use of the food diary and the trial diet. The skin tests make the best point of departure at the beginning of the study, for when positive they afford a definite starting point in the formulation of the diet. Any allergic diet must be followed rigorously for at least two weeks before one can be certain of results. If, after this, symptoms persist one may have recourse to the food diary, where symptoms are intermittent, or to the trial or elimination diet where they are more constant, or indeed to a combination of both. In keeping a food diary the patient tabulates all the substances which pass the lips. Each day he adds a new food at the bottom of the list. He notes methods of cooking and food combinations. It is not sufficient, for example to record "eggs." Scrambled eggs and omelet are reported as entirely different foods. Roast beef and steak are separated. Salads are classified according to their constituents. Days on which symptoms are manifested are checked. Not infrequently certain foods stand out as being often or constantly present on those days or on the preceding day. If the food diary does not solve the problem elimination diets may be tried. If the eliminative diet fails it may be because of crossed reactions within a biological group of foods. Vaughn has, therefore classified vegetable foods biologically, as, for example, under *Graminae* he places wheat, rye, barley, oat, rice, and corn. He has found that where one member of a biological food group has proved to be allergic to an individual, other members of the same group may cause allergic symptoms, even though the skin reaction has been negative. Sensitivity to one member of a group, however, does not necessarily imply sensitivity to all other members of the same group. On the basis of his observations, Vaughn has arranged a foundation list of foods consisting of those which are infrequently allergenic and of foods such as are not closely related genetically to others. After eliminating any food to which the patient gives a positive skin reaction and any which experience has caused him to suspect, a diet is built up upon the remaining apparently innocuous foods. As a rule new foods are added singly and not more than one every third day. Vaughn emphasizes that it is not sacrilege for the allergist to employ other therapeutic measures than purely allergic, directed against other related nonspecific factors such as intestinal stasis, bile tract infection, ulcer, diabetes, tuberculosis, etc.—*American Journal of the Medical Sciences*, October, 1931, clxxxii, 4.

The Antagonistic Action of Leucemia and Tuberculosis in the Human Organism.—In the course of the last 10 years, says Gottfried Holler, in the *Klinische Wochenschrift* of September 5, 1931, there have come under his notice a dozen cases of leucemia combined with tuberculosis, which revealed a very characteristic antagonistic influence of the two morbid processes upon one another, and in which the majority of the patients finally died of miliary tuberculosis. He observed that for a long time only benign deposits of the tuberculous process appeared in these leucemic patients (fibrous apical inflammation, pleurisy that was soon healed, and glandular processes, especially in the abdomen and mediastinum), until at last the tuberculosis appeared in the form of a universal miliary dissemination. All these cases were characterized by a striking leucopenia, expressed chiefly in a loss of granulocytes and a marked increase, for a time, of monocytes and lymphocytes. Of no little importance was the histologic finding in the spleen, which exhibited an increase of the reticulum and the sinus endothelium. In the cases with myeloid leucemia there were a striking number of myelocytes and other immature granulocyte forms, while the cases of lymphatic leucemia abounded in lymphoblasts. Thus there was the picture of aleucemic leucemia, one cause of which was the inflammatory changes in the spleen induced by the tuberculosis. These, taken in connection with the blood picture, suggested the existence of a reticuloendotheliosis. Three case histories are outlined, in one of which a lymphatic leucemia was removed by a lymphogranuloma of each lung—a morbid process which, in the most modern view, is etiologically related to tuberculosis. The two stages were clearly marked by the change of the blood picture from a high grade leucocytosis into a leucopenia, and by a change in the type of cells flushed into the blood from a relative hyperlymphocytosis to a hypermonocytosis. Conversely the author has observed leucemia supervening in cases of tuberculosis, which then assumed a very long, slow course. There existed for example in a lymphatic blood picture an enlargement of liver and spleen, but for a long time there was no participation of the peripheral glands, or else the leucemic process was confined for a long time to a single group of glands. Frequently the diagnosis could be made only by excision and examination of a lymph gland.

LEGAL

A SURGEON RECOVERS FOR DISABLING INJURIES

By LORENZ J. BROSNAN, ESQ.

Counsel Medical Society of the State of New York

A case of great interest to the medical profession was the subject of a recent decision by the Circuit Court of Appeals in one of our mid-Western States. We feel, because of the importance of the case, that it merits a very detailed review in these columns.

The plaintiff was a physician, the defendant an insurance company. The action was brought on a policy of accident insurance which the physician had taken out with the company prior to the incident which formed the subject-matter of the action. The yearly premium on this policy was $750. One of the provisions included in the policy was a weekly indemnity of $250 for total disability which would prevent the assured from performing the duties pertaining to his occupation. The plaintiff had, for about twenty-seven years prior to the commencement of the action, devoted himself entirely to the practice of surgery in a large mid-Western city. During the policy period the doctor accidentally fell on the sidewalk in front of his house. At the time he was carrying a glass jar, and the fall broke the jar, lacerating his right hand and wrist. The median nerve was severed and clearly the result was a serious impairment in the use of the hand and wrist.

The doctor claimed that the injury so sustained constituted a total disability within the meaning of the policy. The insurance company resisted this contention, whereupon about two years after the injury the doctor instituted suit against the company and recovered payment for total disability over the period of time that he had been incapacitated subsequent to the injury. Sometime later he instituted the present action to recover for permanent disability.

On its face the policy showed that it provided compensation for accidental injuries to the plaintiff, a surgeon engaged in his occupation of surgical practice. The answer of the defendant insurance company included allegations that the doctor was not in fact wholly disabled, and that he could still engage in the practice of his profession even though he could not perform manual operations. This allegation was based on the theory that the profession of the plaintiff was "surgical practice" and that term included, in addition to the actual operating of cases, at least three other types of work. They were described as, first, the diagnosis of the mental, physical and nervous condition of the patient; second, the care of the patient preparatory to or subsequent to an actual operation; and, third, duties as a consulting surgeon who does not actually operate. The company contended that the plaintiff was able to perform duties of this sort and, therefore, was not prevented wholly from engaging in surgical practice.

On the trial, it seems to have been established beyond doubt that the doctor's hand was still seriously injured. He testified that as a direct result of the accident he had lost the faculty of sensation in the major part of his right hand and, except for the little finger and part of the palm of the hand, it was really useless. He swore that he was no longer able to diagnose properly by two-handed palpation and that he could not properly handle the instruments necessary to do surgical work. He also testified that he had submitted to five operations and an extended course of treatments in an attempt to regain the usefulness of the hand, but that these operations and treatments had not been successful and the hand had in fact become worse. The doctor also told the Court that he had made no attempt to resume his practice, as he well understood the responsibilities of a surgeon and knew that to do so would throw him open to charges of malpractice on the part of the patient.

The defendant introduced medical testimony to show that with injuries similar to those sustained by the plaintiff it was still possible to engage in surgical work. By agreement between the parties, the doctor called five witnesses besides himself and so did the company. All of the company's witnesses were crippled, some worse than the doctor, and all professed to be successfully engaged in some phase of surgical practice, and all of them agreed that surgical practice could be carried on by one unable to use instruments. These witnesses contradicted the plaintiff's witnesses as to what the description "surgical practice" covered, implying that it did not necessarily include the ability to use surgical instruments or to operate with them on human beings.

The crux of the case depended upon the interpretation given to the term "surgical practice" in the policy. When the Court charged the jury upon this point, he defined "surgery" as follows:

"Surgery is a branch of medical science. It is limited to manual operations usually performed by surgical instruments or appliances."

Counsel for the insurance company requested the Court to charge upon this point as follows:

"The occupation covered by the policy and for which the plaintiff was insured, is surgical practice. Surgical practice means the general practice of surgery by one authorized by law to engage in such occupation, under the ordinary circumstances in which a surgeon follows such occupation, and applies to one skilled in the knowledge of medicine and surgery. The occupation of surgical practice is not limited solely to the performing of manual operations, but includes all material duties, as disclosed by the evidence, involved in the occupation of surgical practice."

The Court, however, declined to so charge. Apparently it did not agree with the defendant's contention that the term "surgical practice" is somewhat broader than the word "surgery," and of course under the Court's charge "surgical practice" within the meaning of the policy implied of necessity the ability to perform manual operation.

The jury returned a verdict in favor of the physician and from the judgment entered thereon the insurance company appealed to the Circuit Court of Appeals. That Court, with one Judge dissenting, affirmed the judgment below. One of the principal points raised by the insurance company on this appeal was that the theory of their defense had not been fairly submitted to the jury by the Trial Court. Upon this point the Circuit Court of Appeals said:

"Admittedly it had to be boiled down for submission to a jury. So analyzing the mass to define the theory we find that it proceeds from the obvious fact that the performance of the duties of every professional occupation includes and presupposes in the professional the exercise of many trained and developed powers. Conspicuously every such occupation includes the duties skillfully to observe, to estimate, to apprehend and to prepare for conditions and to consult with others about them and to resolve upon them preceding, accompanying and following professional action. And in all the professions there are specialists There are theologians who do not preach, lawyers who try no cases, doctors who administer no potions and surgeons who never incise. Observing that surgical practice in no wise differs from all professional occupations in this general aspect, defendant centered upon a certain number of such incidents of the surgical practice, like diagnosis, consultation, preoperating and post-operating attention and so forth, and developed that cripples could do those things and some other things and make a living at it, and it contended that the doctor could likewise. * * * It was a fair defense and no impropriety is charged in the conduct of it. But, however elaborated the defense remained as succinctly epitomized in defendants' answer, 'that by reason of the ability of the plaintiff to do and perform many of the duties hereinabove detailed and many other duties hereinabove detailed and many other duties pertaining to the occupation of surgical practice, the plaintiff is not entitled to recover.'"

The Court then went on to discuss generally the provisions of accident policies, with special reference to the policy before the Court, and said:

"Such accident policy provisions have been before the courts time out of mind. It has always been obvious that an absurdly literal construction could be put upon such words as 'any and every duty pertaining to my occupation' which would reduce the coverage for total disability to the states of coma or absolute mental and physical helplessness. But the fact that money is paid and accepted for accident insurance under these policies compels attributing good faith to the parties and a construction of the words used in the policy conformable to an honest intention to indemnify against total inability to practically carry on the occupation specified. * * * It appears * * * that the doctor's injuries were to his hand only and that the doctor's health was good save for the lost eye and the crippled right hand. Accordingly it must be deemed well and firmly settled that such total disability provisions of any accident policy as here presented do not limit recovery to cases of coma or complete helplessness, nor is recovery precluded because the insured gets well enough to follow some other occupation than the one covered by the policy. * * *

"Obviously the words of this clause, 'prevent the insured from performing one or more material duties,' like the words of the other clause, 'prevent the insured from performing any and every duty,' could be absurdly construed to describe a state of helplessness. In a strained sense one flat on his back unable to move is merely 'prevented from performing' more duties pertaining to his occupation than the lone duty of thinking about it. But the same assumption of good faith in the parties prohibits the construction, and the courts con-

strue the clause as consistent with honest intention to indemnify against partial disability."

In holding that the case had been fairly tried and the issue resolved in favor of the doctor by the jury and, hence, no legal reason was found in the record to disturb the verdict of the jury, the Court said:

"Whether the doctor was malingering or actually disabled was before the jury every moment of the trial. The jury must have believed that the doctor could not practice surgery if he tried. The word 'disabled' carries that implication clearly and unequivocally. To couch the same thought in the terms of duty adds words but no substance. * * *

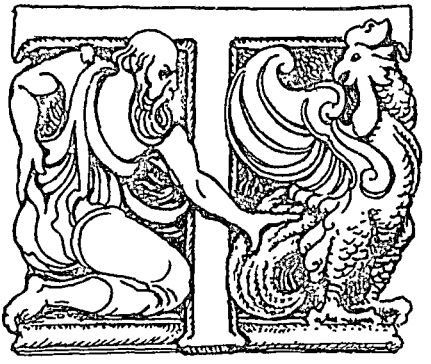
"On the whole case it is evident that reasonable minds may well differ as to whether a man of Doctor M's physical and mental vigor has been totally disabled for surgical practice. But it has been settled by the jury upon a fair trial most ably contested by counsel on both sides."

RECURRENT HERNIA

In this case a young woman of heavy build consulted the defendant, a physician and surgeon specializing in surgery, complaining that she was suffering from a rupture. Upon examining her the doctor found that she had a bilateral indirect hernia, and he suggested an operation to which the proper consent was given.

The doctor performed a modified Bassini operation, under a general anesthesia, which operation was roughly described as opening the skin and the sac; then isolating and tying off the sac and the conjoined tendon being sewed over to Poupart's ligament; and the facia of the oblique external muscle being closed and sutured with chromic catgut, and the skin being sutured likewise with catgut. Bandages and dressings were applied and the patient remained in the hospital for about nine days, at the end of which time she was discharged, her progress up to that point having been extremely satisfactory.

During her hospitalization the doctor daily changed the dressings himself and after her discharge the patent returned to him in order that he might change the dressings weekly for the next several weeks. At the date of the last of such treatments the wound was entirely healed and the doctor discharged her as no longer needing medical care.



Some months later a suit was instituted against the defendant doctor based upon a claim that the hernia had recurred and that the plaintiff had been obliged to undergo a subsequent operation for the treatment of double oblique inguinal hernia. The plaintiff charged the defendant with being negligent in that he failed to perform a "process of grafting" knowing that the plaintiff was a stout woman at the time of the operation, and further that the defendant was negligent "in that he allowed and permitted large fatty deposits of tissue at the site of said rupture or hernia to remain therein; in that he negligently caused the incisions of and around said rupture to open; in that he failed to perform sufficient sutures, in consequence of which said sutures could not hold together and opened immediately after the performance of said operation." The case regularly came on for trial and the defendant and his attorney appeared in court ready to proceed with the defence of the action, but the plaintiff failed to appear. The court, therefore, on motion of the defendant's attorney, dismissed the case, finally terminating the matter in favor of the doctor.

NEWS NOTES

MEDICAL INITIAL LETTERS

THE use of ornamental first or initial letters of chapters and paragraphs, done in symbolic designs, was a familiar device for illustrating or illuminating ancient manuscripts. The NEW YORK STATE JOURNAL OF MEDICINE, throughout its thirty-one years of existence, has used a boldfaced initial letter three lines deep to begin each article in its scientific department. This particular article begins with the initial letter "T," five lines deep, drawn by Dr. Robert L. Dickinson. The design is based on a stone carving over the window of the large assembly hall of the building of the New York Academy of Medicine. It represents Hippocrates, the Father of Medicine, about to grasp a cock, the symbol of vigilance and the appropriate sacrifice to Æsculapius, the God of Healing.

The Academy of Medicine building is ornamented with symbolic carvings of men and animals appearing over the lintels of doorways and windows. The importance and appropriateness of these symbolic figures are indicated by their inclusion in stone in the Academy building.

Dr. Dickinson considers these designs to be worthy of display at the beginning of every scientific article. He therefore offers a specimen of the initial letter "T" as a demonstration of illumination appropriate for a medical journal, such as THE NEW YORK STATE JOURNAL OF MEDICINE, or the Bulletin of the Academy of Medicine.

SUFFOLK COUNTY

The 125th Annual Meeting of the Suffolk County Medical Society was held on Thursday, October 29, in the Henry Perkins Hotel, Riverhead, with the President, Dr. W. J. Tiffany, in the Chair. A business meeting was opened at 12 o'clock noon, and was followed by a luncheon. A scientific session was held in the afternoon. There were present 39 doctors of the Society, and 30 guests, including public health nurses and wives of the members.

The Secretary reported that the Comitia Minora had held three meetings during the six months since the last meeting of the Society, and that one of the meetings was for the purpose of formulating plans to the cooperation of the physicians of the County with the County Health Department in combating the epidemic of poliomyelitis. (See this Journal, September 1, 1931, page 1103.)

The Secretary, Dr. E. P. Kolb, reported on the routine work of the Secretary's office, and said that all matters of general interest had been published in the Monthly News Letter of the Society.

The Treasurer reported in detail on the finances of the Society.

Dr. A. T. Davis, for the Publication Committee, reported "that the News Letter had been issued regularly and that about 250 new names had been added to the mailing list, the additional cost being taken care of by the County Health Dept."

Dr. Frank Overton, Chairman of the Public Health Committee, reported on the satisfactory cooperation of the physicians with the County Department of Health, and on the questionnaire sent to doctors to ascertain the prevalence of venereal diseases as a preliminary step to an active campaign against those diseases at the expense of the County Health Department, according to a State law passed last Winter, requiring counties having county health departments to provide treatment for venereal patients who otherwise could not obtain treatment This law is similar to the welfare law which is working well in the County.

Dr. Arthur T. Davis, County Health Commissioner, gave a detailed report on the recent poliomyelitis epidemic. This report covered the distribution, age incidence, sex, percentage of deaths and paralysis, etc. He reported that about 8000 c.c. of immune serum had been secured from 25 donors. Dr. Davis expressed his appreciation of the hearty cooperation given the Department of Health by the practicing physicians of the County.

Dr. W. H. Ross, Chairman of the Economic Committee, gave a detailed report of agreements made with the County Welfare Commissioner in regard to the care of patients under the Welfare Law. The report was unanimously adopted, and was as follows:

"The Committee on Economics of the Suffolk County Medical Society held three meetings with Welfare Commissioner Ernest Van Hise, and Hospital Superintendents, and agreed upon the following standards for the administration of that part of the State Welfare Law relating to medical services to those persons who are unable to secure necessary medical care:

"1. The family physician of the patient shall be employed as in private practice.

"2. The employment of a doctor shall be authorized by the Commissioner of Welfare, or one of his fifteen local deputies

"3. When a doctor is called to attend a patient under the Welfare Law, he shall at once notify the Commissioner or his deputy, and get a written authorization for his attendance. This authorization must be renewed every two weeks for continued attendance.

"4. In an emergency case the physician shall give the proper treatment at once; and within forty-eight hours he shall obtain the proper authorization for his treatment.

"5. Additional authorization shall be obtained for unusual procedures, such as *x*-rays, laboratory analyses, consultations, and surgical operations.

"6. The following principles shall be considered as standard in regard to medical fees:

"Office call $2.00
"Visit to the house 3.00
"Visits at a hospital, two dollars per day regardless of the number of visits.
"Obstetrical case 25.00
"Prenatal office visits during a period of four months previous to confinement, each 2.00
"Surgery fee, to the surgeon... $5.00 to 50.00
"Surgery fee, to the medical assistant, 5.00 to 10.00
"Surgery fee, to the anesthetist $5.00 to 10.00
"Hospital charge, including basic laboratory examinations, per day..... 3.50
"One necessary *x*-ray plate shall be taken free and additional ones shall be authorized by the Commissioner or his deputy.

"7. The Committee on Economics of the Suffolk County Medical Society offers its services in arbitrating disputes regarding medical bills or services."

The Society voted its confidence in the County Health Department, in the following resolution:

"RESOLVED, That the Suffolk County Medical Society hereby reaffirms its opinion first expressed in 1926 that public health administration can only be efficiently done by county organization (to replace township part-time organization); that after three years of experience the local profession more strongly than ever believes that the efficiency of public health practice is greatly improved by county organization; and that the physicians of the County have found that a County Health Department is an asset in their professional work and an asset to their economic welfare."

The following officers were elected for the year 1932:

"President, Charles C. Murphy, Amityville; Vice-President, Joseph H. Marshall, Southold; Secretary, Edwin P. Kolb, Holtsville; Treasurer, Grover A. Silliman, Sayville; Censors, Wm. J. Tiffany, Wm. N. Barnhart and Louis A. Garben; Delegates to State Society, Albert E. Payne and Chas. C. Murphy; Alternates, Edwin P. Kolb and Arthur T. Davis; Delegate to Second District Branch, Wm. H. Ross."

The following new members were elected:

"Drs. Abraham I. Goldschlager, Islip; Victor K. Young, Riverhead; Morris W. Molinoff, Brentwood; Vincent A. Doroszka, Patchogue; Ethel H. Trygstad, Brightwaters; Arthur E. Corwith, Bridgehampton; Roland G. Vaughn, Amityville; and Cathryn V. Riley, Patchogue. By transfer from the Ontario County Medical Society, Dr. Hiram R. Barringer, Bay Shore; and from the Kings County Medical Society, Dr. Morris R. Keen, Patchogue."

The program of the Scientific Session consisted of two papers, as follows:

1. President's Address, on "Modern Ideals in Medicine," by Dr. William J. Tiffany, Kings Park.

2. "Treatment and After-Care of Poliomyelitis," by Dr. Walter Truslaw, Brooklyn.

EDWIN P. KOLB, *Secretary.*

BRONX COUNTY

A regular meeting of the Bronx County Medical Society was held at Elsmere Hall on November 18, 1931, at 9 p.m. with the President, Dr. Irving Smiley, in the Chair.

The following doctors were elected to membership: Drs. Nathan Block, Emil G. Conason, Arnold A. Constabile, Julius Dankberg, David Diamondstone, Louis Richard Ferraro, Benjamin Fleissig, Joseph Harkavy, Max B. Kampf, Joseph Melton, Israel Pine, Angelo Procaro, I. Jerome Silverman, Nathaniel Sipilesko, S. Sydney Tausend, Felix P. S. Vogel, and Lionel Charles Rubin (Associate Member).

Dr. H. L. Frosch, who with Dr. Samuel Gitlow represented the Bronx County Medical Society on the Subcommittee on Pathological Laboratories of the Coordinating Committee of the Five County Medical Societies, reported relative to proposed modifications of the sanitary code affecting clinical laboratories. These modifications were referred to the county societies for their approval. Dr. Frosch explained the modifications recommended and asked for the approval of our society as recommended at the last meeting of the comitia minora. The report was accepted and the recommendations were approved.

Dr. E. N. Lefcourt, Chairman of the Social Committee, reported relative to the proposed beefsteak dinner and show to be held on December first, and appealed for the cooperation of the doctors.

Dr. B. H. Archer, for the Committee on Medical Economics, reported on the special economic meeting being arranged by the committee, to be held at Elsmere Hall, on Monday evening, December 7, 1931, at which the topic for discussion will be "A plan to prevent the wholesale, indiscriminate practice of medicine and surgery by the City of New York," presented by Dr. C. J. O'Connor, of the committee. Dr. Archer urged the members to attend the meeting and to give the committee their earnest support.

The President called attention to the joint meeting of the organized medical and dental professions, which will take place at the Hotel Pennsylvania, on Monday, November 30, and asked for a large representation from our society.

The Scientific Program then proceeded as follows:

Paper: Benign and Malignant Tumors of the Breast: Early Diagnosis, Treatment and Prognosis (Lantern Demonstration), Joseph C. Bloodgood.

The paper was discussed by Drs. Burton J. Lee, Henry Roth, Abraham O. Wilensky, Bradley L. Coley, William Klein and Charles S. Rogers. The discussion was closed by Dr. Bloodgood.

I. J. LANDSMAN, *Secretary.*

FRANKLIN COUNTY

The annual meeting of the Medical Society of the County of Franklin was held in the lecture room of the Alice Hyde Memorial Hospital, October 28, 1931.

The following members were present: Dr. P. E. Stamatiades, President, in the chair; Dr. H. Beattie Brown, Vice-President; Dr. G. F. Zimmerman, Secretary-Treasurer; Dr. G. C. de Grandpre, Censor; Drs. D. M. Brumfiel, E. N. Packard, J. W. Price, S. F. Blanchet, A. G. Wilding, C. E. Stickney, A. L. Rust, R. H. Mayhew, P. F. Dalphin, J. W. Blackett, W. H. Kingston, F. F. Finney, D. C. H. Van Dyke, E. E. Thurber, E. M. Austin, and J. E. White. Visitors, Dr. S. W. Sayer, District State Health Officer, Gouverneur, N. Y., and Dr. A. H. Hyman, Faust, N. Y.

The Secretary's report showed fifty-three members in good standing, while two were dropped in 1931 for non-payment of dues.

The following officers were elected for 1932:

President: H. Beattie Brown, Saranac Lake.

Vice-President: J. W. Kissane, Malone.

Censor for three years: E. M. Jameson, Saranac Lake.

Delegate to State Society meeting 1932: C. C. Trembley, Saranac Lake.

Dr. Anthony B. Gedroiz, of Saranac Lake, was admitted to membership.

The Committee on Medical Economics reported that an agreement had been reached with the supervisors of Franklin County providing remuneration to physicians for the hospital care of indigent patients, and a schedule of fees had been agreed upon. This agreement dates from July 1, 1931.

Dr. Jameson on behalf of the Saranac Lake Medical Society extended a cordial invitation to all members of the County Society to attend their meetings, these meetings to be held every two weeks from November to March, beginning November 4th.

Dr. White addressed the meeting on the subject of auto accidents where settlements of hospital and physicians' bills are made by the carriers directly to the injured, instead of to the hospitals and physicians themselves. In many cases the injured refuse to pay their hospital and physician's bills after receiving money for that purpose from

the carriers. It was moved, seconded and carried that a petition be forwarded to the State Medical Society and to the Legislative Committee asking that legislation be fostered to correct that condition.

The following petition was framed and mailed to the Legislative Committee of the State Medical Society.

"The Medical Society of the County of Franklin petitions the Medical Society of the State of New York and its Legislative Committee to foster such legislation as is necessary to compel insurance companies to assume the payment of hospitals and physicians for attendance on victims of automobile accidents, such bills to be paid directly by them to the hospitals and physicians concerned."

SCIENTIFIC SESSION

The following papers were presented:

1. Poliomyelitis: Dr. S. W. Sayer, Gouverneur.
2. The Use of Some of the Newer Drugs in Heart Disease: Dr. D. M. Brumfiel, Saranac Lake.
3. Home Treatment versus Sanatorium Treatment in Pulmonary Tuberculosis: Dr. R. H. Mayhew, Malone, N. Y.

G. F. ZIMMERMAN, *Secretary.*

BROOME COUNTY

The Broome County Medical Society held its regular monthly meeting in the Art Gallery of the Arlington Hotel in Binghamton, November 10, 1931.

The usual business session, which included at this time the nomination of officers of the Society for the ensuing year, preceded the educational program which was given over to Dr. B. H. Nichols, Director X-ray Department, Crile Clinic, Cleveland, Ohio. Dr. Nichols's subject was "Role of the Roentgenologist in Pain of the Upper Right Abdominal Quadrant," and was profusely illustrated with picture demonstrations. The address covered the subject in a very painstaking and detailed way and exemplified the keen observations and vast experience of this high authority.

There was a full attendance, including guests from adjoining Counties.

HENRY D. WATSON, *Secretary.*

FIRST DISTRICT BRANCH

The twenty-fifth annual meeting of the First District Branch of the Medical Society of the State of New York was held on Wednesday, October 7, 1931, in the Hotel Palatine, Newburgh. The President, Dr. Charles D. Kline of Nyack, Rockland County, presided.

The First District Branch is composed of three county societies of Greater New York—Richmond, New York, and Bronx; and four Hudson Valley societies—Westchester, Dutchess-Putnam, Rockland, and Orange. Seventy-five members from these seven county societies were present.

The meeting began with a social gathering as the members began to assemble at noon. A luncheon was served at one o'clock followed by after-dinner speaking.

Dr. W. D. Johnson, President of the Medical Society of the State of New York, outlined some of the ideals of a family doctor, illustrating his remarks with apt quotations of poetry.

Dr. Charles G. Heyd, President-Elect of the State Society, gave a brief description of a visit to France as one of a group of official medical visitors to the French government.

Dr. John A. Card, Speaker of the House of Delegates and Chairman of a special committee on indemnity insurance, made a plea that every doctor should take advantage of the reduced rates offered for indemnity insurance by the Etna Insurance Company under on agreement with the State Society.

The scientific session was of unusual interest and value, and the program included four speakers as follows:

I. "Medical Nomenclature," H. P. Logie, M.D., New York Academy of Medicine.

II. "Compensation and the Doctor," V. A. Zimmer, Director of Compensation Division of the State Labor Department.

III. "Some Phases of Circulatory Failures and Their Treatment," Marcus A. Rothschild, M.D., New York.

IV. "Lung Abscess—Newer Phases of Treatment," Harry Wessler, M.D., New York.

THE DAILY PRESS

DARWINISM IN VERSE

Modern animals may be survivals of the fittest amid changing swamps and mountains and plains; or they may be the result of an orderly development like that which takes place in the mind of man as his childish notions blossom into the creations of reason. James J. Montague inclines to the older idea of Darwinism in the following verses in the New York *Herald Tribune* of November 9:

"The pterodactyl was a fowl
Much larger than a hawk or owl,

And furthermore, as you will find,
He was a bird and brute combined.

Combine an eagle and a bat
And it will help you to get at

What pterodactyls really were—
Great flying beasts that had no fur,

As well as brutes which had no growls
Because they partially were fowls.

No members of this curious race
Abide today in any place.

They merely show how Nature tried,
With small experience for a guide,

To fashion things which might survive,
And eat and drink and fight and thrive

Upon this rolling mundane sphere,
And prove that they belonged down here.

This proof remained quite unsupplied
And so the simple creatures died.

So you and I should both be glad
That later on our chance we had,

When Nature found, by 'cut and try,'
That we'd be able to get by,

And prove at last that we were worth
Preserving long upon the earth."

NECESSITIES OF LIFE

Cigarettes are not necessities of life in Chicago, according to the following item in the New York *Herald Tribune* of November 6:

"Two packages of cigarettes, J. L. Jacobs, county efficiency expert, estimated today, cost the county $246. He stood with a stop watch in his hand yesterday while the county Board of Commissioners debated the question of whether they should pay 30 cents for the two packages, the cost of which was listed on a bill for meals for a jury. Mrs. Glenn Plumb, one of the commissioners, protested, contending that cigarettes are not lunch.

"The debate which followed lasted for fifteen minutes, but in the end the commissioners decided they could not be expected to furnish smokes for jurors.

"'I've been doing some figuring,' Mr. Jacobs said. 'At the rate you commissioners and the stenographers and other employees are paid, it cost the county $246. And that doesn't count the cost of heating this room.'"

On the other hand the New York *Times* of November 30 predicts that cosmetics may be necessities in Philadelphia:

"Society leaders and business women insist cosmetics are necessities, although a bill has been introduced at the special session of the Legislature to tax sales of cosmetics 10 per cent on the ground that such preparations are luxuries.

"'Cosmetics are as much a necessity as toothpaste,' says Mrs. Pauline B. Peters, president of the Philadelphia Club of Advertising Women. 'They are a necessity because a good appearance is a necessity—a business necessity.'

"'Rouge, powder and lipstick are psychological necessities,' asserts Mrs. H. Maurice Snyder, former chairman of juniors for the State Federation of Pennsylvania Women.

"'I think the importance of a woman's looking well lies in her looking well to herself. Her morale is boosted 100 per cent when she does.'

"Mrs. William L. Van Leer of the Junior League calls cosmetics an essential 'part of a woman's physical hygiene.'"

TRUTH vs. FICTION

The most serious truth-teller may seem to be a liar, or a vaudeville entertainer, when he explains natural phenomena to an ignorant audience. Thus did an Englishman to an audience of Hindus when he told of water becoming hard so that men walked on its surface; and thus did Dr. Roy Chapman Andrews seem to an audience of prisoners on Welfare Island, New York City, when he told them of dinosaur eggs found in the Gobi Desert when he was leading a research expedition of the American Museum of Natural History. The *Tribune* of November 23 says:

"Dr. Roy Chapman Andrews gained the incredulous applause of the workhouse gathering on Welfare Island yesterday afternoon with his strange tale of the Chinese dinosaur eggs that were 95,000,000 years old. Some of the inmates of the place seemed to think it was the funniest story they had ever heard; they roared with laughter when he assured them that the eggs really were that old and after he had finished the lecture, they had him return again 'to the egg part' and tell it again.

"His audience listened indifferently as Dr. Andrews began. He was the man who had been to Asia looking for Adam. He talked about the windstorms, the wild asses which roamed the desert, they were mildly interested when he told them that an antelope wrapped in a man's fur-lined vest had escaped one cold night. They listened to him tell about fish in lakes a thousand miles from the ocean. However, as he came to the dinosaur eggs, they became interested.

"Some sat with a rapt expression; some opened their mouths, stared and listened; they looked at one another, half smiled and when Dr. Andrews said 'You may think I am an awful liar,' they shouted with laughter.

"They wanted to know why anyone should go so far for eggs that were so old; they wanted to know how much it had cost to get the eggs and to bring them here; they wanted to know where the eggs were now.

"'Professor,' inquired a Negro woman, 'how come if you say an animal as big as a dinosaur laid those eggs, how come the eggs aren't bigger? Seems like they ought to be big as a grand piano.' Dr. Andrews explained that the animal which had laid the eggs was nine feet long and that the eggs were nine inches long. 'So,' he said, 'we have one inch of egg for one foot of dinosaur so that shouldn't be so bad for a record.'

"One negro boy wanted to know how long it would take eggs 95,000,000 years old to hatch. They told him as soon as they got off the island they were going straight to the American Museum of Natural History and see the thing for themselves."

COCKROACHES

Physicians who are sanitarians are compelled to take an interest in the cockroach from a human point of view; and those doctors who are biologists study it because it has survived almost unchanged from early geological ages. An editorial writer in the New York *Times* of November 9 has hit upon information which doctors' wives may cherish when he says:

"Cockroaches, the American Association for the Advancement of Science informs an eager world, lose about 9 per cent of their body weight daily in dry air at 86 degrees Fahrenheit; in four days they die.

"This will be gratifying news to housewives, especially in New York. They will have merely to maintain for four days an even temperature of 86 degrees Fahrenheit in the proverbially dry air of their apartments and the cockroaches will vanish. Thereby will be created more technological unemployment as science drives the exterminators out of business.

"Too little attention, aside from applications of various pastes, powders and what not, has been given to the cockroach. Few of us, for example, have taken time to learn that it is 'a blattid orthopterous insect especially abundant in hot countries,' although most of us knew that it is 'chiefly nocturnal.' Furthermore the Croton bug, or, in more recent years, water bug, which in our ignorance we fancied was native to this city and its environs, is in truth an alien—the German cockroach, *Phyllodromia germanica,* to be exact?"

BOOK REVIEWS

QUANTITATIVE CLINICAL CHEMISTRY. By JOHN P. PETERS, M.D., M.A., and DONALD D. VAN SLYKE, Ph.D., Sc.D. Volume 1, Interpretations. Octavo of 1264 pages, illustrated. Baltimore, The Williams & Wilkins Company, 1931. Cloth, $12.00.

The authors have enriched American medical literature with an extremely valuable textbook. The volume represents the product of the labors of two leading authorities in their respective fields. Although the book is entitled a Clinical Chemistry, it essentially treats with the chemical aspects of clinical medicine. There are exhaustive chapters on the chemistry and metabolism of the foodstuffs, an extensive discussion of the clinical syndromes associated with deranged metabolic functions, and an accumulation of the literature of every subject discussed. Thus diabetes mellitus becomes the subject of an extensive elaboration in these chapters. The chapters on Protein and Non-protein Nitrogen lead up to a complete dissertation on the nephritides. Uric acid and gout make up the material of another chapter. There are many valuable therapeutic suggestions presented and discussed on a profoundly scientific, physiologic basis. It contains a chapter on hemoglobin and oxygen with their direct clinical applications to cardiac disease, pneumonia, carbon monoxide poisoning, anemia, and the chronic respiratory diseases. Other subjects presented of extreme clinical value are those of body fluids and edema; acidosis; alkalosis; the role of the inorganic constituents of the blood and tissues, including calcium magnesium, sodium, potassium, phosphorus, sulphur and chlorides. The book contains a fine chapter on the acid-base balance of the blood with a description of the diseases which affect the balance. This book thus represents the accumulation of the most recent knowledge of the chemical basis of diseased states.

It is a step in a new direction, and takes a place with structural pathology as a factor in the elucidation of the pathogenesis of internal diseases. No physician can practise modern medicine without a thorough acquaintance with the information presented in this monumental text-book. It will undoubtedly become an invaluable adjunct to the medical student for his training in biological chemistry, physiology, medicine and therapeutics. It is recommended by the reviewer as the best text-book of its kind in English literature.

WILLIAM S. COLLENS.

NUTRITION AND DIET IN HEALTH AND DISEASE. By JAMES S. MCLESTER, M.D. Second edition. Octavo of 891 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1931. Cloth, $8.50.

The author has issued a second edition and has brought up to date a very valuable book. The introductory chapter is concerned with the metabolism of foodstuff and energy requirements of the body. Dr. McLester presents a very logical dissertation on the protein requirements of the body with recent observation on the physical effects of high protein diets among Eskimos and Arctic explorers. The author also quotes the interesting work of McCoy who pointed out the poor physical state of the Bengali, living on a low protein ration compared with the fine physique of the Sikhs, a high protein-consuming race. That together with Whipple's studies on the value of meats in blood building seem to dissipate the fear of the production of renal damage by liberal protein diets. The author also gives a concise but clear presentation of the vitamin, mineral and water metabolism of the body.

There is an interesting chapter on Satiety value of foods, normal menus, and the economics of the normal dietary. Then follows a chapter on Food Products, with a description of the chemical composition, preservation, canning and cost of the common foods. Among them are included dairy products, meat, fish, eggs, cereals, and vegetables. An important statement found in this chapter is concerned with the general misconception among physicians that there are chemical differences between red and white meats, particularly regarding salt content.

There follow chapters on the normal diet, and the diet during reproduction. The author has added a chapter on toxemia of pregnancy to the new edition. The book also contains a chapter on Infant Feeding by McKim Marriott. The second part of the book is concerned with nutrition in disease. The author presents the dietetic requirements together with practical methods of dietetic management of the following groups of diseases: deficiency diseases, diabetes mellitus, gout, obesity, anaphylaxis, disorders of the genito-urinary and gastro-intestinal systems, febrile conditions, vascular disease, skin diseases, and the feeding of surgical patients. The book closes with a valuable section on methods of feeding, cooking, and numerous important tables of use in nutritional work.

WILLIAM S. COLLENS.

FOOD ALLERGY: Its Manifestations, Diagnosis and Treatment with a General Discussion of Bronchial Asthma. By ALBERT H. ROWE, M.S., M.D. Octavo of 442 pages. Philadelphia, Lea & Febiger, 1931. Cloth, $5.00.

It is with much interest and pleasure that we have reviewed Dr. Rowe's book on "Food Allergy."

Of recent years the internist and the allergist have become discouraged with the results of skin tests using the foods, especially in adults. Repeated negative results have made it seem almost useless to do this kind of testing in many cases. In his book Dr. Rowe has offered a very reasonable explanation of this and has shown us a way out of the dilemma. His "elimination diets" will mark a real advance in the diagnosis and treatment of allergy. His chapters on allergic migraine, canker sores, urticaria and the intestinal types of allergy are very valuable. He has reached the conclusion that in many cases these conditions may be attributed to food very careful medical investigation to rule out other disallergy but he has reached this conclusion only after eases or conditions as etiological factors.

The reader gains the distinct impression that the work is sound and that the conclusions drawn are not over enthusiastic. Because of the complicated nature of the diseases due to allergy and the painstaking care required to arrive at a diagnosis, it becomes more and more apparent that the complicated and obscure cases can best be handled by internists who are devoting themselves to allergy.

Dr. Rowe's book marks a real contribution to this field of study and should be invaluable as a reference book for internists as well as allergists.

E. P. MAYNARD, JR.

OUR NEIGHBORS

CHIROPRACTORS IN CALIFORNIA

The October number of *California and Western Medicine* contains the following interesting news notes regarding chiropractors in California:

"The minimum standards as to equivalent quantity and quality in training as laid down by Class A Medical schools are not excessive and, being reasonable and proper, should be the basic minimums which would be demanded of all persons who sought the legal sanction of the State to go before the public, as being competent to treat the diseases and injuries of human beings.

"However, and unfortunately, California adopted the course of not applying basic standards of minimum preliminary and professional education in healing art matters. As a consequence, each year sees the licensure, not only of a considerable number of medical graduates from institutions demanding proper basic minimum standards, but also witnesses the advent into the fold of licensed practitioners of an unusually large number of graduates of sectarian or cultist schools, the standards of which schools in some cases are considerably below those of the majority of medical schools of even some twenty or thirty years ago!

"The inspection of the registration figures of Los Angeles County which were printed in the September *California and Western Medicine* of last month, page 238, reveals how such a double or multiple board system works out in actual practice. The sectarian school known as the chiropractic, for instance, which secured its legal recognition in California about the year 1923, has since that time turned out many graduates, and the California Chiropractic Board of Examiners has granted legal recognition to a large number of such. For figures on these points see the item above referred to, and also *California and Western Medicine* of July, 1930, page 517, and December, 1930, page 915.

"From the statistics available it would appear that within less than ten years a total of about three thousand graduates in chiropractic have been granted licenses to practice the healing art in California. It is probably a safe assumption to affirm that the majority of these graduates probably did not have a complete high school education in the way of preliminary training, and that the professional curricula of their respective schools were far, far below those which would be construed as equivalent to the curricula of Class A medical schools of America.

"In California and some other states—even though such sectarian or cultist graduates possess educational and training qualifications far below the minimum standards laid down by the best American and foreign schools of medicine—their graduates are none the less granted licensure privileges which permit them to go before the people of California on equal basis with graduates of Class A schools. Such a state of affairs, of course, is dreadful inconsistency. However, at this late day little or nothing can be done in the above premises because the citizens of California through initiative vote have granted these sectarian groups legal rights which not even the legislature can change.

"What is of importance to the people of California, however, is the attempt now seemingly being started in California which, if it goes on to fulfillment, will give a certain number of chiropractor licentiates the right to obtain from their board an extension of their fields of practice in that they would be given chiropractor physicians and surgeons' certificates, probably equal in scope and powers to physicians and surgeons' certificates as granted by the Board of Medical Examiners of the State of California.

"For some time now, in the Sunday magazine section of the *Los Angeles Times*, the '—— College of Chiropractic' of Los Angeles, and latterly its presumable successor, the '—— College of Chiropractic,' have printed advertisements which read as follows: 'Become a Doctor of Chiropractic. Learn a dignified profession. Students receive a thorough training at this institution. Our course is complete in every detail and includes: dissection, chemistry, *x*-ray, electrotherapy and obstetrics. There is an abundance of clinic work. We have added an extra 1,000 hours of medicine and surgery which is optional to the student. Day and evening classes. Enroll now. Write for literature. State board quiz classes.'

"We have been informed that the last named school now has about sixty students to whom it has been stated it is giving a physicians and surgeons' course, with the implied understanding that such students probably later on may be able to obtain physicians and surgeons' licenses.

"If the above information be not in error, California may add to its list of physician and surgeon licentiates a new group, so that it would then have the following ensemble:

"1. As at present, graduates of nonsectarian medical schools holding 'physicians and surgeons'

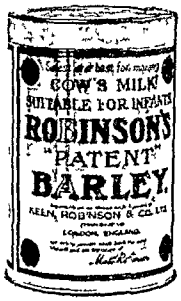
Modifier.. Diluent.. Demulcent..

IN the bottle feeding of infants, physicians have long recognized the value of Robinson's "Patent" Barley as a modifier of cow's milk.



The addition of Barley Water makes the mixture curdle in a manner similar to human milk—in small clots, rather than large clots as in the case of cow's milk. It is thus made more digestible.

As a diluent, it not only replaces plain water, but, since it contains a small amount of starch, Robinson's "Patent" Barley gradually adapts the infant to starchy foods which will later form the major part of his diet.

In digestive disturbances, Barley Water is a particularly valuable drink, since in addition to containing a high percentage of water, it possesses demulcent properties which render it soothing to the intestines. These properties are a result of its colloidal, non-irritating nature.

• • •

LEADING SPECIALISTS today also specify Robinson's "Patent" Barley as an invaluable aid in the treatment of infant diarrhea and other digestive disturbances.

ROBINSON'S "*PATENT*" BARLEY *is prepared in a strictly hygienic factory from the finest barley. It is subjected to routine biochemical and bacteriological tests in order to control its quality. It is a uniform and clean product, free from irritating husks and from bleaching agents.*

Robinson's "*Patent*" Barley

Standard since 1823

If Epsom Salt cost $1 a pound

Puretest refining processes would not be so surprising

Every physician thinks of Epsom Salt as a good old friend. In the class of saline evacuants, a more effective drug has never been found.

No doubt you have often wished that it might be a little less crude, a little more refined. But you have said, "After all, Epsom Salt is just Epsom Salt, and so long as it is up to U.S.P. standards, we can ask no more."

But you *can* ask more today, and you can get more. In Puretest Epsom Salt.

Puretest Epsom Salt exceeds U.S.P. requirements in several important points. It contains a smaller percentage of chlorides, heavy metals, and all other impurities.

Puretest is put through more rigid reaction tests, more refining processes than ordinary Epsom Salt of U.S.P. grade.

All this painstaking scientific care in manufacture, testing and shipping, results in a purer, more refined product—a product which you can prescribe for your patients and know that you have designated the highest quality obtainable.

Why do the makers of Puretest go to all this extra expense and labor to raise a product so low in price, from an accepted commercial grade to a highly selected, refined quality?

Simply because we believe a drug or remedy intended for internal use by human beings *must be the very best* which scientific knowledge and methods can produce.

We will gladly send you a sample for your own personal examination, or any Rexall or Liggett Drug Store will show you Puretest Epsom Salt.

HOW PURETEST EPSOM SALT EXCEEDS THE ORDINARY U.S.P. GRADE

1. It contains a smaller percentage of chlorides, heavy metals and other impurities.
2. Its form is more uniform—a clear, sparkling white needle crystal form with a minimum of fines and impurities.
3. It is subjected to more rigid reaction tests.
4. It is put through a greater number of, and more exacting sampling tests.
5. It shows greater speed and completeness of solubility.

Puretest Epsom Salt

UNITED DRUG CO., BOSTON, MASS.

Laboratories at Boston, St. Louis, Toronto and Nottingham, England

(*Continued from page* 1528)

certificates granted by the Board of Medical Examiners of the State of California.

"2. As at present, graduates of sectarian osteopathic schools, holding 'osteopathic physicians and surgeons' certificates granted by the California Osteopathic Board of Examiners.

"3. Perhaps in the near future, graduates of sectarian chiropractic schools who would hold 'chiropractic physicians and surgeons' certificates, granted by the California Chiropractic Board of Examiners.

"From the news items in the California Board of Medical Examiners' column in this issue is taken an item which in turn was previously printed in the San Francisco *Call-Bulletin* of August 14, 1931. Readers of *California and Western Medicine* can draw their own conclusions therefrom. The excerpt reads thus:

" 'Move to obtain legislative action which would revoke a surgeon's license in event it could be shown the surgeon performed an unnecessary operation was launched in San Francisco today by the California Chiropractors' Association. Chiropractors are not allowed to practice surgery. According to Dr. Harry C. Bond, president of the organization, seventy-five members voted to draft a measure on the subject for submission to the next legislature.'—San Francisco *Call-Bulletin*, August 14, 1931.

"All the above is here printed in the hope that the component county societies of the California Medical Association will give attention to a subject which is seemingly somewhat important. Let it be remembered that if such legal sanction is once obtained by chiropractic or other sectarian and cultist groups, whereby 'physicians and surgeons' certificates could be granted by their respective boards, that it would then be practically impossible to take away such rights.

"Wherefore it would appear that the time to think and do, is beforehand and not afterward."

CRIPPLED CHILDREN IN NEW JERSEY

The October number of the Journal of the Medical Society of New Jersey contains the following editorial on the care of crippled children:

"The General Assembly of New Jersey, in 1929, passed an Act providing for a Special Commission to make a census of all the crippled children in the state, and in due time all physicians were asked to aid in that task. The profession responded, of course, and as one result of several conferences between the Chairman of the Commission and the Chairman of our Welfare Commission, with the Executive Secretary acting at times as an intermediary, and the State Board of Health coöperating when necessary, a plan was

Ways to Compensate for the "DON'TS" ON THE DIABETIC DIET

If what the patient can eat be made more varied and more appetizing, conforming to the "don'ts" on the diet will seem much less of a hardship. Knox Sparkling Gelatine brings change to the diet without involving deviation from the diet. Its use introduces more than fifty appealing dishes to the diabetic routine—all built up from the basic foods allowed.

The splendid thing about Knox Gelatine is that it can be used freely and safely. It is pure, granulated gelatine. It contains no sugar, no coloring, no flavoring . . . no synthetics of any kind. It combines ideally with other foods.

Knox has prepared a Diabetic Recipe Book. Many physicians have found this book to be valuable, giving it to their patients as a supplement to the diet list. It is available in any quantity for physicians who desire it. For your convenience, a coupon is printed below. Just send it in.

WINTER SALAD *(Six Servings)*

	Grams	Prot.	Fat	Carb.	Cal.
2 teaspoons Knox Sparkling Gelatine	4.5	4	..	..	..
¼ cup cold water	..	..	..	..	..
½ cup hot water	..	..	..	..	..
½ teaspoon salt	..	..	..	..	..
¼ cup vinegar	..	..	..	..	..
1½ cups grated cheese	150	43	54	..	..
½ cup chopped stuffed olives	70	1	19	8	..
½ cup chopped celery	60	1	..	2	..
¼ cup chopped green pepper	25	..	..	1	..
½ cup cream, whipped	75	2	30	2	..
Total		51	103	13	1183
One serving		8.5	17	2	197

Soak gelatine in cold water. Bring hot water and salt to boil and dissolve gelatine in it. Add vinegar and set aside to chill. When nearly set, beat until frothy, fold in cheese, olives, celery, pepper and whipped cream. Turn into molds and chill until firm. Unmold on lettuce leaf and serve.

SPANISH CREAM *(Six Servings)*

	Grams	Prot.	Fat	Carb.	Cal.
1 tablespoon Knox Sparkling Gelatine	7	6	..	..	..
¼ cup cold water	..	..	..	..	..
1 cup milk	240	7	10	12	..
¾ cup boiling water	..	..	..	..	..
2 eggs	100	13	10.5	..	..
1½ teaspoons vanilla	..	..	..	..	..
Few grains salt	..	..	..	..	..
Total		26	20.5	12	336.5
One serving		4	3	2	56

Soak gelatine in cold water five minutes. Heat water and milk [illegible] firm.

KNOX *is the real* GELATINE

IF you agree that recipes like the ones on this page will be helpful, write for our complete Diabetic Recipe Book—it contains dozens of valuable recommendations for the diabetic diet. We shall be glad to mail you as many copies as you desire. Knox Gelatine Laboratories, 432 Knox Ave., Johnstown, N. Y.

TRAINING OFFICE SECRETARIES IN MISSOURI

The Journal of the Missouri State Medical Association for November has the following note on a school for office secretaries:—

"A school for training young women to be efficient office secretaries to physicians has been started in St. Louis. The school is conducted by Miss Mary E. Holliway at 3720 Washington Boulevard. Miss Holliway is eminently fitted to impart this kind of information. She was secretary to Dr. George H. Jones during his eight years of service as secretary of the Missouri State Board of Health. After leaving the State Board of Health Miss Holliway was secretary to Dr. Hanna W. Loeb and is now secretary to Dr. S. B. Westlake. The course offered by Miss Holliway includes, conduct of the waiting room; greeting of patients and types of patients; telephone service to both doctor and patient; economy of the physician's time; clinical instruction in simple conditions; assistance to the physician during examination; care of office equipment; first-aid suggestions; medical terms and dictation of complete case histories in the various specialties; files, accounts, and collections."

GRADUATE EDUCATION IN KENTUCKY

The July issue of the *Kentucky Medical Journal* has the following editorial comment on the Graduate courses in Kentucky:

"The Post-Graduate course, held under the auspices of the Kentucky State Medical Association from June 1st to the 12th, had the largest attendance and was one of the most successful of the summer school that has been conducted by this Association. A faculty of sixty physicians of Louisville gave unstintedly of their time and energy for its success. So appreciative were the doctors attending the school, of the splendid work that was given them, that many requested that they hold night sessions, especially in the laboratory department. Dr. H. V. Noland and fifteen assistants from the laboratory of the State Board of Health during the second week conducted the evening demonstrations at the request of the 28 members registered.

"Dr. P. F. Barbour, Chairman, the Medical Department of the University of Louisville, and the other physicians who gave so generously of their time, are to be congratulated upon the success of this summer school."

BI-NA-GLUCONATE is perfectly stable and sterile It may be boiled without deterioration It is not affected by light or heat Each 2cc represents 0 016 Gm of metallic bismuth with 2% alcohol benzylic as a local anaesthetic

Now a STABLE Bismuth Solution

in True Colloidal State

Exerts Maximum Therapeutic Effect in the Treatment of Syphilis

PHYSICIANS, familiar with the therapeutic value of Bismuth in Syphilotherapy, have desired a stable solution BI NA GLUCONATE being such a stable solution commands the attention of the medical profession

BI-NA GLUCONATE, presenting a Bismuth solution in true colloidal state, recognizes that all life processes take place in a colloidal system, and being in form isomorphic with the elements of the body, will exert the maximum therapeutic action It is quickly assimilated, slowly eliminated, and may be administered without fear of detrimental side actions

BI NA-GLUCONATE is an alkaline organic, water soluble Bismuth salt solution in *true colloidal state* for intragluteal injection Its superiority has been clinically demonstrated

Injected intragluteally, 1½ to 2 inches deep, it has been shown to be painless; absorption certain and complete, and to have the desired therapeutic effect with no evidence of Bismuth toxicity such as stomatitis lead line and salivation

BI-NA-GLUCONATE is supplied in Hyposols (ampules) 12, 25 and 100 in a package. Send for literature

VITAL STATISTICS IN TEXAS

The United States Registration area consist those states whose statistics on births and de are ninety-five per cent reliable. The August i of the *Texas State Journal of Medicine* has an torial headed, "Texas Vital Statistics Recogniz which says:

"We are pleased to announce to the mec profession of Texas that the United States reau of Census has begun the compilation of birth and death rates for Texas cities. The Te records are now being transcribed. A large f is at work in the health department at Austin it is due to be made much larger in weeks to c This is a development that has been devoutly sired by all who are interested in public he matters. . . . The recognition, while pleasing, ries with it a responsibility that the medical fession of Texas cannot overlook or sidestep."

The reasons for refusing the recognition of vital statistics of Texas is indicated by the clo paragraphs, as follows:

"In the preliminary work that has been d we are informed that 1,176 letters were ma in connection with the reports for the month June. On more than three hundred birth reco the reporting physicians failed to state whe the child was alive or still born. On more t fifty of the reports, there was nothing said al the legitimacy or illegitimacy of the child, as quired, and on other reports such essential in mation as the sex, and date of birth, were omit Of course, statistics of this character are dependable. The reporting physician has sir been careless.

"When the check-up begins on the cause death, it is quite likely that even greater disc ancies than these will be found, in view of uncertainty and the differences of opinion an practicing physicians, as to the proper designa of many diseases or conditions which cause d On one of these reports a doctor stated tha saw his patient June 13, and the patient June 6. Another report has it that a patient from ether narcosis, complicated with ur coupled with the statement that there had be surgical operation. Nothing was said as to character of the operation or the condition re ing it. The inference possible in such a would make the information previously useless.

"It is not the purpose of our editorial to di the problem. We merely desire to broadcas information and urge upon our readers that give special and close attention to the prepar of the data called for by the Bureau of Statistics of the State Department of Health that the reports and the correspondence thereto be expedited."

ANNUAL REGISTRATION IN TEXAS

n editorial in the November number of the *us State Journal of Medicine* contains the lowing comment on Annual Registration.

'or years the State Medical Association has erated closely with the State Board of Medi- Examiners in an effort to see that this very ssary and certainly very fair law is used for purpose for which it was intended, namely, protection of the unsuspecting and credulous ic from imposition by inadequately prepared litioners. The State Board of Medical Ex- ers has been, for the most part, without s, and the State Medical Association has to furnish them money. We have been glad o this. It is simply one channel through h we have passed our money in the protec- of the public health.

'he annual registration law becomes effective ary 1. At that time, each practing physician exas will be expected to register with the Board of Medical Examiners, giving much ed data to that governmental agency and ig $2.00 for the privilege of registering and continuing practice throughout the calendar year. The State Board will compile a list of the legalized practitioners of medicine in this state as it stands each year, and will use the registration fee in paying the expenses incident to the adminstration of the law and bringing into account those who are practicing medicine and who steadfastly refuse to obey the law. If the State Board is to be successful in its endeavors, it must know who is practicing medicine in Texas, both legally and without sanction of the law. Last month we editorially asked our readers to help the State Board in locating all such. County Societies have been asked to furnish the State Board with complete lists of the practitioners in their respective jurisdictions. Quite a bit of information has been secured, but far from enough. We are repeating the appeal.

"Incidentally, the members of the State Medical Association who are required to pay the fee will be out nothing, in view of the fact that the annual dues of the State Medical Association have been reduced in the amount of the fee."

RADON

We announce the following prices anywhere in the United States and Canada

GOLD RADON IMPLANTS

Millicuries	Per Implant
1.0	$4.00
1.5	5.50
2.0	7.00
2.5	8.50
3.0	10.00

Our price is based on the Radon content at the hour of use. ¶ The GOLD RADON IMPLANTS are 0.3 millimeter pure gold. ¶ Certificate of Guarantee furnished with each Radon preparation assuring accurate dosage. ¶ Instruments loaned without charge if returned in good condition within five days after you have used them.

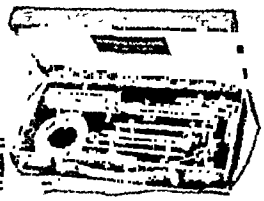
ELECTRICALLY LIGHTED SURGICAL INSTRUMENTS



"E. S. I. Co."

The mark that stands for quality and service also represents a complete line of electrically lighted instruments for specialists in practically every field.

The tenth edition of the E. S. I. Co.'s catalog is interesting because it not only outlines the wide scope of the line, but describes the most recent developments in this important field.

Write today for a free copy . . . sent postpaid.

ELECTRO SURGICAL INSTRUMENT CO.
ROCHESTER, N. Y.

MEN ARE NOT IMMUNE

EXCESSIVE perspiration does not search out its victims by sex. Men just as often suffer from its discomforts as women. This is especially true of hyperidrosis of the axillae, hands and feet.

The physical discomfort and social implication of excessive perspiration are equally distressing to men and women.

NONSPI

(AN ANTISEPTIC LIQUID)

checks the perspiration and prevents the odor, too. It needs to be applied only once or twice a week to those parts of the body not exposed to adequate ventilation. Trial supply gladly sent to physicians on request.

YES, I'd like to try NONSPI. Please send me a free trial supply.

PUBLIC RELATIONS IN CALIFORN

The November number of *California and We rn Medicine* records the establishment of a D partment of Public Relations as follows:

"At this year's annual session of the Californ Medical Association of San Francisco, the Hou of Delegates, at its meeting of April 30, 19 instructed the Council to take steps to create 'Department of Public Relations.'

"The special committee's report as adopt provided that 'An Advisory Committee of Publ Relations be established, composed of the chai men of the component committees or commi sions on,—*Public Policy and Legislation:* Med cal Economics: Hospitals and Clinics: Healt and Instruction: and the Cancer Commission,'- with the president, secretary, and, general coun sel of the California Medical Association, ex officio.

"It was further voted that an effort be mad to secure the services of a competent colleagu either from California or some other state, wh would be the executive secretary of the depar ment, and who would also act as director of th Department of Public Relations.

"It was further voted 'that the work and re sponsibilities of the present standing committee or commission shall be in no way curtailed, bu that their grouping into the department shall b considered to be for the purpose of increasin their activity and efficiency.'

"It was also voted that the members of th Committee on Public Relations should be calle together at an early day for the purpose of o ganization and of development of the work o this department.

"As soon as this is done, further informati will be given members of the California Medic Association through a Public Relations Depar ment column in the official journal, which colum will probably find a place in the California Med cal Association department of California an Western Medicine."

CHIROPRACTORS IN RHODE ISLAN

The Rhode Island Medical Journal for Nove ber contains the following editorial comment the new chiropractic law:—

"Such chiropractic-physicians shall be entit to the same services of the laboratories of State Public Health Commission as are availa to physicians qualified to practice medicine section 3 of chapter 159 of the general laws, a they shall be subject to the same duties and l bilities and entitled to the same rights in t practice of their profession as may be imposed

(*Continued on page* 1555—*Adv. xxi*)

(*Continued from page* 1554—*Adv* ix)

n by law or regulation upon or to physicians
ther schools, except that they shall not write
criptions for drugs for internal medication
practice major surgery

This is an excerpt from the Public Laws
nding the chiropractic Act and passed in
January Session of 1931 It permits chiro-
tors the same privilege as those granted phy-
ns except the prescribing of drugs for internal
ication and major surgery What constitutes
or surgery is not defined

As the law now stands a candidate for exam-
on for a chiropractic license must have at-
ed an approved school of chiropractic for
2 years of nine months each as a resident
ent The preliminary educational require-
t for entering a chiropractic school is a high
ol or its equivalent The candidate must be
ears of age at the time he applies for exam-
on

The examining Board consists of two physi-
s and a chiropractor The subjects examined
re anatomy, physiology, histology, embry-
y, chemistry, laboratory diagnosis, hygiene
sanitation, philosophy of chiropractic, spinal
analysis, pathology, physical diagnosis, *X*-ray,
first-aid, gynecology and dietetics The law re-
quires that the Public Health Commission must
approve of and sign the license of all candidates
certified as successful by the Board of Examiners
in Chiropractic

"Obviously the examination of candidates in
medical subjects cannot be as rigid as those re-
quired of physicians, for they could not pass them
because of the limited education which they re-
ceive And yet, they are permitted to treat any
kind of illness, to sign death returns and are given
most of the privileges granted physicians From
time to time they will come to the State Legisla-
ture for further privileges as they have already
done

"Even the best trained physicians know little
enough about the diagnosis and treatment of dis-
ease and injury And yet the State sees fit to put
the stamp of approval on those who, because of
the lack of education, know little about disease
and its manifestations This certainly shows
little appreciation on the part of the public offi-
cials of their responsibility for the safeguarding
the health of the individual, and public health in
general"

THERAPEUTIC ALMANAC

NOVEMBER

DECEMBER

Thanksgiving and Christmas cheer within. Snow, slush and bleak winds without. Influenza strikes; other febrile and respiratory ills, pneumonia, infectious diseases follow. Acidosis comes with them—or it may precede and predispose to disease.

℞ ALKA-ZANE

A teaspoonful in a glass of water, taken after effervescence has subsided, three times daily, will guard the alkali reserve and furnish active alkalization.

Note—Alka-Zane combines the carbonates, phosphates and citrates of sodium, potassium, calcium and magnesium. No sulphates, tartrates or lactates; no sodium chloride.

PLAN FOR RURAL MEDICAL SERVICE IN KENTUCKY

The November number of the *Kentucky Medical Journal* contains the following news item regarding the action taken by the county societies on rural medical service:

"The Carlisle and Ballard County Medical Societies, believing that adequate medical service in Kentucky should be made available to all of her people, and

"Believing that it is the duty of the State, County and Community to co-operate in providing such needs, and

"Believing that faulty distribution, rather than insufficient numbers of Physicians in the State, constitutes the heart of the problem;

"The Carlisle County Medical Society, and, The Ballard County Medical Society, declares that it is their judgment that:

"(1) Doctors should not be expected to practice Medicine where facilities are such that they cannot render efficient service.

"(2) That Community Hospitals and Group Practice would attract young graduates to locate in rural districts.

"(3) That our Legislature should raise its appropriation to 50 per cent of the cost of Rur Hospitals.

"(4) That County Fiscal Courts can ma appropriations to build and maintain Hospit as well as Court Houses or Public Schools. T health of a County is as vital to the happiness its people as is education or legal processes.

"(5) That Rural Doctors realize the handic under which they work, and should assume t leadership in uncovering the cause, and discov ing the remedy for its relief."

The Journal also prints a leading article on t plan, written by Dr. R. C. Burrow, of Cunnin ham, a member of the committee on medical ser ice from Carlisle County. The doctor sums up report of an investigating committee, as follow

"They call attention to Governor Sampson message to the 1929 session of the General Asse bly, in which he recommends establishing a Sta Medical School, and the subsequent introducti in the House, of a bill for such a school. Th and other suggestions in their pamphlet, leads t to feel that their final solution to the problem state medicine.

GASTRIC ULCER
Needs More than Neutralization

Yet, neutralization has an important job to do in gastric ulcer. It prepares the field so that treatment may be effective. CAL-BIS-MA measures up fully to this requirement. It places no faith in gastric ferments to act out of their element. It relies on sodium and magnesium for quick neutralization, on calcium for prolonged effect, on bismuth for protection of the mucous membrane, on *colloidal kaolin* for adsorption of gases and toxic substances. There is no penalty to pay in discomfort by excessive gas formation, the colloidal kaolin takes care of that; no constipation from prolonged use, magnesium prevents that; no secondary acid rise—every ingredient in Cal-Bis-Ma guards against it.

In Gastric Hyperacidity

CAL-BIS-MA

Cal-Bis-Ma is not merely theoretically correct. You can soon prove it practically efficient by sending for a trial supply.

WILLIAM R. WARNER & COMPANY, Inc., 113 West 18th Street, New York City

(*Continued from page* 1556—*Adv. xxii*)

"The time is short. The Legislature will meet ain very shortly and this pamphlet is propa- nda, getting ready for measures for state medi- ie during the next session." . . . . . "It is up the profession to find something better than ite medicine, and so inform our Legislature fore their next meeting. The scarcity exists, t state medicine will make it worse by driving t the independent doctors.

"I am suggesting Health Units, Group Practice, d *Community Hospitals as the remedy, hoping* it the membership of this society presents it, or nething better, to our state society, so that the ofession will be ready for united action to pre- it state medicine."

After listing the equipment which a young doc- needs (including an electrocardograph), the author says:

"Give the young graduate a chance to join a oup where his outlay for equipment will be ly his proportionate part of the group, and iny will leave the crowded cities, where there one doctor to every three or four hundred ople, and locate in the rural districts, where ere is only one physician to every two thousand people, and where specializing would not be drawn to such narrow limits.

"Community hospitals, with an adequate number of nurses, would figure largely in relieving the scarcity of physicians in rural districts (and the supply of nurses seems to be adequate for all needs.) The hospital should belong to the community, and should not be maintained or operated for profit. Let the group of doctors be required to furnish the equipment as listed above. It matters little how the hospital is built, whether by fiscal appropriation from county or state, or both, or church, or by public subscription. It would be far cheaper on the state to appropriate money for community hospitals, the amount of such appropriation to be matched by an equal sum from the county or community, than it would be for the state to build and finance state medical schools. It would do far more toward furnishing efficient medical service. State medical schools would do but little good toward meeting the issue without the community hospital, but give us community hospitals and it will be a long time before there will be a lack of physicians to run them.

"Carlisle County has one physician to every

when dyspeptics beg for quick

IN functional dyspepsia and gastric neuroses, quick symptomatic relief is afforded by the digestant and sedative Pancreobismuth and Pepsin. And whenever there is insufficient or faulty digestion from any cause, Pancreobismuth will help to supply the needed digestive enzymes.

Pancreatin, pepsin and taka-diastase* provide for digestion of protein, fat and carbohydrate. Bismuth subnitrate allays gastric and intestinal irritation.

RELIEF

Sodium bicarbonate supplies antacid. And powdered ginger is stomachic and carminative.

This tried formula will serve you well for relieving sudden attacks of dyspepsia due to dietary indiscretion and also the more protracted types of gastric or intestinal disorder when the physiological secretions are deficient.

Prescribe ½ to 1 teaspoonful in a wineglassful of lukewarm water after meals.

*Uniform in composition and 2 to 6 times more potent than ordinary malt diastase.

fourteen hundred population, and no one ever suffers for lack of medical attention, unless it is the 'dead-beat.' Those deserving of charity are not allowed to suffer. Give us a hospital, the necessary equipment mentioned above, the help of technicians and nurses, and one doctor can render efficient service to a population of two thousand, and at a price they are able to pay."

POPULAR MEDICAL PUBLICITY IN IOWA

The first report of the special committee on Publicity of the Medical Society of the State of New York (see this Journal, December 1, 1931, page 1469) calls to mind what other State Societies are doing in popular health publicity. The Journal of the Iowa State Medical Society for November, 1931, page 640, contains the following summary of the work of the Speakers' Bureau:

"The Bureau established a new record last month in sending forty-five speakers to thirty-one meetings. This number compares very favorably with that of long established bureaus. In order to keep this comparison favorable, however, we must make this number of talks an average month instead of a record one. To do this, we need help. The Bureau is still a new project in the state. There is a tremendous lot of work to be done in educating the public to secure its health speakers from proper sources. Here is where the individual physician, the county medical society, and the woman's auxiliary can be of infinite value to us. Let people know that the Iowa State Medical Society maintains a Speakers' Bureau, and that the list of speakers is carefully selected and kept up to a certain definite standard. Only part of this can be done by correspondence. Repetition of this information will make the Bureau a familiar name to the public. We are anxious to reach the schools, service clubs, luncheon clubs, women's clubs, Y. M. C. A., Y. W. C. A., and Farm Bureaus, in every locality in Iowa. This lay education program is one of the most important activities in the state society and is fundamental to the success of many others.

"The Bureau is always anxious to promote programs among the county medical societies. With the beginning of the fall programs, there are being presented many new interesting and valuable facts gleaned from the study during the summer months. The county medical society secretaries are urged to send in the names of any of their members who have presented especially good papers which should be shared and enjoyed by the members of other societies. Now is a good time to schedule competitive exchange programs between county medical societies of similar size."

ANNUAL REGISTRATION IN COLORADO

The November issue of Colorado Medicine eports the appointment of a special committee a annual registration, as follows:—

"Considerable discussion of the annual regis- ation fee law in the House of Delegates at e Colorado Springs meeting resulted in crea- on of a new special committe for this year, e Committee on Investigation of the State egistration Fee. In the creation of this com- ittee it was directed that a thorough study the annual registration plan be made, both regards its comparatively recent establish- ent in Colorado by the 1929 legislature, and ncerning its operation, successful or other- ise, in such other states as have similar laws.

"The committee is asking that it be given e help and cooperation of every member of e Society in the collection of such informa- on, so that the committee may be accurately formed as to the operation of the law in all rts of the state."

The article also contains the text of the gistration law passed in 1929. The annual e is two dollars, and is to be deposited in a ecial fund known as the "Medical Board egistration Fund," from which disbursements e to be made by the proper officers of the ate Board of Medical Examiners. The article es not state the purposes for which the fund ay be used.

INANCES OF THE MEDICAL SOCIETY OF PENNSYLVANIA

The annual reports of the officers and committees of the Medical Society of the State of ennsylvania are printed in the September num- r of the Journal of the Society The principal ems may be summarized as follows:

"RECEIPTS"

Membership due @ $5.....	$49,463.36

ECONOMICS IN ARKANSAS

The economic status of Arkansas doctors is discussed on the President's page of the November Journal of the Arkansas Medical Society by Dr. D. A. Rhinehart is follows:—

"When asked about his practice, a physician from one of the smaller towns of the State said that the last he had was fine. Others, when asked the same question, have most often replied that the business of practicing medicine has gone on about as usual, but that the financial remuneration is considerably below average.

"In traveling over the State I find few signs of bad effects of the flood, the drought, or the industrial depression. In an agricultural district there is little unemployment during a crop-growing period. Arkansas certainly has been blessed with one of the best feed and food-growing seasons ever experienced. There is an abundance of produce of all kinds.

"In the immediate future in Arkansas, people will have plenty to eat, but there will be little money to pay for pleasures, luxuries, and unusual expenses such as medical care. The economic status of physicians is, on the average, the same as that of the communities in which they live and practice. During the coming year, in most parts of the State, physicians may expect as many calls as usual for their services, but they must not expect so great a monetary return. Such money as they receive must be expected from those financially in better circumstances than the average and from those whose income is from various sources."

MEDICAL EDITORSHIP IN NEBRASKA

An editor's work is the same in Nebraska as in New York, as is shown by the following editorial in the December issue of the *Nebraska State Medical Journal:*

"This number completes Vol. XVI of the *Nebraska State Medical Journal* and the editor leaves it to the reader to say whether t *Journal* is worth while. An edito has his ideas and his conceit about the work he does on a jour nal. This editor has long sinc learned that one cannot expect ap plause from the medical reade The profession takes a lot fo granted and as long as the reade sees nothing special to kick abou he says nothing audibly withi hearing of the editor, leaving hir to form his own conclusions.

"This editor likes state medica journalism, he gives the best h has to the work and he hopes th reader likes the resultant produc He pleads for continued and in creasing cooperation of the profes sion and welcomes suggestions an constructive criticism."

COLORADO LOOKS AT NEW YORK

The October number of *Colo rado Medicine* has this to sa about a chiropractor on Lon Island:

"Chiropractic took a hard slug ging in a Jamaica, L. I., court la week. William H. Werner, pres dent of the American Bureau c Chiropractic, was on trial fc practicing medicine without a l cense. His income from chir practic treatments and teachin was figured to be $70,000 a yea Some 200 of his patients, who b lieved him a martyr, jammed int the courtroom where they cause so much disturbance that the tri judges had them ejected.

"Chiropractor Werner was martyr to his cause in one sens Regular medicine, including hon eopathy, uses drugs, surger physical therapeutics, every po sible means to prevent and cur disease. Chiropractic in essenc believes that spinal manipulatio (one form of physical therapy) sufficient to prevent and cure.

"In New York when rich Wi liam H. Werner, doctor of chir practic, treats the sick for pay, h has no more legal standing tha a Pennsylvania 'hexer.' He trie to harangue the judges on chir practic. They squelched him an sentenced him to six months in th workhouse."
